

# MINUTES OF THE 47th GENERAL ASSEMBLY OF THE EUROPEAN ASSOCIATION FOR THE STUDY OF DIABETES

held in Lisbon International Fair, Portugal, Thursday 15 September 2011 at 18:00

Present:	Dr. U. Smith	(President)
	Dr. A.J.M. Boulton	(Vice President)
	Dr. F. Bosch	(Vice President)
	Dr. G. Spinas	(Honorary Treasurer)
	Dr. M. Walker	(Honorary Secretary)
	Dr. J. Zierath	(Editor-in-Chief, Diabetologia)
	Dr. C. J. Tack	(Chair, PGEC)
	Dr. V. Jörgens	(Executive Director)
	Dr. M. Grüsser	(Vice Director)
	and 47 members	

The President, Dr. Smith, welcomed everyone to the 47th General Assembly.

## 1. MINUTES 46th GENERAL ASSEMBLY 2010

Since there were no comments, the minutes were approved unanimously and officially signed as a correct record.

## 2. REPORTS

### a) President

The President's report to the members on the activities of EASD was given in the President's Address before the Minkowski Lecture. It is available under:  
<http://easd.conference2web.com/content/1029>

The President reported on the various activities and expressed his thanks to all partners. The postgraduate courses continued to be successful and attracted many young researchers. Dr. Smith reported that as expected the EASD Annual Meeting this year in Lisbon is doing very well and the number of delegates attending has increased. Dr. Smith thanked all members of the EASD Office and the Executive Committee, for their commitment and hard work.

### b) Honorary Treasurer

Dr. Spinas reported that EASD is doing very well financially. The income had increased in 2010 by approx. one million Euros from membership, registration fees and earnings from the Stockholm Annual Meeting. He said the administrative cost of 2.15% is very low. The expenditure had increased in 2010 because funds had been made to the Foundation.

Dr. Spinas expressed his thanks to the Executive Committee and to Drs. Grüsser and Jörgens for their support and advice and to the dedicated professional team in Düsseldorf. Special thanks were given to Mrs. Klee, Mrs. Deparade-Oertel and Ms. Weiss for the precise handling of the accounts. As his term of office was coming to an end, Dr. Spinas said farewell and expressed that it has been a very rewarding time and a tremendous privilege for him to serve as Honorary Treasurer and that EASD was living up to its mission.

The President thanked the Honorary Treasurer and on behalf of the Executive Committee for his diligence and asked if there were any questions. There were no further comments.

**c) Honorary Auditors**

The President asked the Honorary Auditor, Dr. Roden for his report. Dr. Roden confirmed that the accounts had been checked carefully and were in perfect order. Dr. Smith asked for the vote to accept the accounts.

The Honorary Treasurer was unanimously discharged (38 votes for and 1 abstention).

**d) Honorary Secretary**

Dr. Walker reported that 2145 abstracts had been submitted; of the 1352 which were accepted 264 were orals. The top three countries for abstract submission were USA, UK and Germany.

Dr. Walker also reported that there had been positive response to the App.

Dr. Walker closed his report by thanking all members of the EASD staff, in particular Ms. H. Goliberzuch and Mrs. M. Toledo, for their outstanding help and support with the organisation of the EASD Annual Meetings.

Dr. Smith thanked Dr. Walker for his diligence and asked if there were any questions. There were no further comments.

**e) Editor-in-Chief, Diabetologia**

Dr. Zierath briefly reported that the impact factor of Diabetologia was the highest ever and the journal continued to be successful. She also expressed her thanks to the team in Bristol and the outgoing associate editors Drs. Bierhaus and Beguinot.

Dr. Smith thanked Dr. Zierath for her enthusiasm and dedication to the journal.

**f) Chair, Postgraduate Education Committee**

Dr. Tack also reported that the web education sessions were progressing very well. Dr. Tack thanked Brian Carey, Leona Pecirep and Mary Hata for their friendly assistance.

Dr. Smith thanked Dr. Tack for his diligence in his role as Chair of the Postgraduate Education Committee.

**g) Chair, Extra-European Postgraduate Activities**

Dr. Boulton reported on the successful three courses: Nepal in November 2010, China in December 2010 and Best of EASD-India Course held in Cochin and Bangalore in February 2011 had all been very well attended. Dr. Boulton reported that courses were being planned in

China and South Africa. Dr. Boulton expressed his thanks to the staff of EASD in particular Mary Hata; he also thanked the sponsors and the collaboration with ADA and IDF.

Dr. Smith thanked Dr. Boulton for his hard work in organising the extra-European activities.

**3. ELECTIONS****President (2011–2014)**

The General Assembly unanimously approved the election of Dr. A.J.M. Boulton with 45 votes and 1 abstention.

**Vice President (2011 – 2014)**

The election of Dr. S. Del Prato was unanimously approved with 46 votes and 1 abstention.

**Honorary Treasurer (2011 – 2014)**

The election of Dr. M. Roden was unanimously approved with 46 votes and 1 abstention.

**Council Members (2012 - 2015)**

The election of Drs. H. Beck-Nielsen, S. Bolgarskaya, A. Novials Sarda and R. Weitgasser was unanimously approved with 44 votes and 3 abstentions.

**Honorary Auditor (2011 - 2014)**

The election of Drs. P. Diem and L. Gardete-Correia was unanimously approved with 46 votes and 1 abstention.

#### **4. STUDY GROUPS**

Dr. Boulton reported that the EASD Study Groups and representatives had been invited to a forum during the Annual Meeting. At the forum he noted that presently, the format of constitution varies greatly across the study group. Dr. Boulton also suggested that study group members would be ideal candidates for EFSD grant reviewers and encouraged all study groups in listing the names of potential reviewers.

#### **5. HONORARY MEMBERSHIP**

The nomination for Dr. C. Wollheim was unanimously approved. Dr. Smith thanked Dr. C. Wollheim for his outstanding contribution to diabetes research.

#### **6. ANY OTHER BUSINESS**

Dr. Wim Wientjens thanked EASD for their marvellous work. He also commented the possibilities if future IDF meetings would eventually be allowed to take place in the EU. Dr. Pierre Lefèbvre suggested that talks between the EASD Executive Committee and the IDF board should take place.

Dr. Smith thanked Dr. Wientjens and Dr. Lefèbvre for their comments and assured them that EASD and IDF are continuously in correspondence with each other. Dr. Smith thanked the industry for their support. He also expressed his sincere gratitude to the Local Organising Committee for their outstanding contribution to the organisation of the 47th EASD Annual Meeting. The President warmly thanked Dr. Jörgens and the EASD team in Düsseldorf for their dedicated work.

Dr. Smith brought the General Assembly to a close at 18:50.

# Agenda for the 48th General Assembly of the European Association for the Study of Diabetes

to be held in the Rubner Hall, Messe Berlin, Germany  
on Thursday 4 October 2012 at 18:00

## 5. Honorary Membership

## 6. Any other business

# 48th EASD Annual Meeting of the European Association for the Study of Diabetes

Berlin, Germany, 1 – 5 October 2012

## Abstracts

### Index of Oral Presentations

- OP 01 Incretin based therapies
- OP 02 Impact of bariatric surgery
- OP 03 Hyperglycaemia and the brain
- OP 04 Insulin action in the liver
- OP 05 New modulators of energy expenditure
- OP 06 What's new in the treatment of diabetic nephropathy?
- OP 07 What's new in insulin therapy?
- OP 08 Diagnosing and treating diabetic neuropathy
- OP 09 The effects of interventions in reality
- OP 10 Type 2 diabetes: from risk models to survival
- OP 11 Links between obesity, inflammation and insulin resistance
- OP 12 Dynamics of beta cell signal transduction
- OP 13 Nutritional approaches to body composition and liver fat
- OP 14 Can we improve outcomes in diabetic pregnancy?
- OP 15 Role of the immune system in type 1 diabetes
- OP 16 Mechanisms of insulin action
- OP 17 Mitochondria: signalling power plants of the beta cell
- OP 18 The -omics frontier: applications of new technologies
- OP 19 Novel therapies
- OP 20 Insulin: beyond traditional delivery
- OP 21 Stem cells in chronic complications
- OP 22 Mitochondria and insulin action
- OP 23 Complications and biomarkers
- OP 24 The transcriptome of healthy and stressed beta cells
- OP 25 Intervention studies in type 1 diabetes
- OP 26 Causes and consequences of diabetic nephropathy
- OP 27 New pathways involved in the cross talk between immune cells and metabolic tissues
- OP 28 Type 1 diabetes mellitus: acute and chronic complications
- OP 29 Genetics of type 1 and type 2 diabetes
- OP 30 Beta cell function in vivo
- OP 31 The importance of glycaemic control: results from large scale studies
- OP 32 Insights in diabetic retinopathy
- OP 33 Devices, algorithms and their application
- OP 34 Profiling glucose and clinical trials
- OP 35 Regulators of adipose tissue expansion
- OP 36 Non-coding RNAs in the beta cells
- OP 37 Metformin actions and benefits
- OP 38 Hypoglycaemia
- OP 39 Diabetes education and its clinical impact
- OP 40 Glucose fluctuations and cardiac complications
- OP 41 Modifiers and markers for cancer in type 2 diabetes
- OP 42 Changes over time in type 1 diabetes

- OP 43 SGLT-2 inhibitors
- OP 44 Mechanisms of incretin action
- OP 45 Diabetes and depression
- OP 46 Foot ulceration: Can we do better?
- OP 47 Tuning into the rhythm of clock genes in diabetes
- OP 48 Imaging beta cell mass in vivo

### Index of Poster Sessions

## OP 01 Incretin based therapies

1

### Liraglutide trial in paediatric subjects with type 2 diabetes: safety, tolerability and pharmacokinetics/pharmacodynamics

T. Battelino<sup>1</sup>, D. Klein<sup>2</sup>, D.J. Chatterjee<sup>3</sup>, P. Hale<sup>3</sup>, C.T. Chang<sup>3</sup>, S. Arslanian<sup>4</sup><sup>1</sup>University Medical Center, Ljubljana, Slovenia, <sup>2</sup>Cincinnati Children'sHospital Medical Center, Cincinnati, <sup>3</sup>Novo Nordisk Inc, Princeton,<sup>4</sup>University of Pittsburgh School of Medicine, USA.

**Background and aims:** Prevalence of T2D is increasing in adolescents and the need for more treatment options is escalating. We investigated the safety, tolerability, pharmacokinetics (PK) and pharmacodynamics of liraglutide QD in adolescent subjects (10–17 years old) with T2D in a randomised, double-blind, placebo-controlled trial.

**Materials and methods:** Subjects on diet/exercise or metformin were randomised 2:1 to liraglutide (14) or placebo (7) injections. Starting at 0.3 mg, doses were escalated weekly to 0.6, 0.9, 1.2, 1.8 mg/day (or placebo equivalent) for 5 weeks.

**Results:** Nineteen subjects completed the trial. Groups were matched at baseline, with mean (SD) age 14.8 (2.2) years, weight 113.2 (35.6) kg, diabetes duration 1.7 (1.4) years and HbA<sub>1c</sub> 8.1% (1.2%). No serious adverse events (SAEs), including severe hypoglycaemia, were reported; AEs were mild in liraglutide-treated subjects and mild to moderate in placebo-treated subjects. Transient, dose- and body weight-independent gastrointestinal AEs were most common at lower doses of liraglutide (Table). There were no significant changes in other measures of safety and tolerability. No pancreatitis was reported and calcitonin levels were within the normal range in all subjects and did not increase meaningfully with liraglutide. After administration of 1.8 mg liraglutide, mean  $t_{1/2}$  was 12 h and CL/F 1.7 L/h, similar to observations in adults ( $t_{1/2}$  = 13 h, CL/F = 1.2 L/h). After 5 weeks, the decline in HbA<sub>1c</sub> was greater with liraglutide vs. placebo (-0.86 vs 0.04%,  $p=0.0007$ ), while mean body weight remained stable (-0.50 vs -0.54 kg,  $p=0.9703$ ).

**Conclusion:** Liraglutide was well-tolerated in a paediatric cohort with T2D, with safety, tolerability and PK parameters similar to those in adults.

**Table.** Summary of gastrointestinal AEs, hypoglycaemic events by liraglutide dose and by randomised group and calcitonin levels.

	Lira 0.3 mg	Lira 0.6 mg	Lira 0.9 mg	Lira 1.2 mg	Lira 1.8 mg	Total lira	Total placebo

### The once-weekly human GLP-1 analogue semaglutide provides significant reductions in HbA<sub>1c</sub> and body weight in patients with type 2 diabetes

M.A. Nauck<sup>1</sup>, J.R. Petrie<sup>2</sup>, G. Sesti<sup>3</sup>, E. Mannucci<sup>4</sup>, J.-P. Courrèges<sup>5</sup>, S. Atkin<sup>6</sup>, M. Düring<sup>7</sup>, C.B. Jensen<sup>7</sup>, S. Heller<sup>8</sup><sup>1</sup>Diabetes Centre, Bad Lauterberg im Harz, Germany, <sup>2</sup>University of Glasgow,UK, <sup>3</sup>University Magna Graecia, Catanzaro, Italy, <sup>4</sup>Careggi TeachingHospital, Florence, Italy, <sup>5</sup>General Hospital, Narbonne, France, <sup>6</sup>Hull YorkMedical School, Hull, UK, <sup>7</sup>Novo Nordisk, Søborg, Denmark, <sup>8</sup>University of

Sheffield, UK.

**Background and aims:** Semaglutide is a unique acylated human GLP-1 analogue with a half life of 160 h. The aim was to investigate HbA<sub>1c</sub> dose response of once weekly (OW) doses of semaglutide in subjects with T2D. Safety, tolerability and pharmacodynamics of semaglutide vs placebo and open label once daily (OD) liraglutide were also investigated.

**Materials and methods:** In a 12-week, randomised, double-blind, placebo-controlled trial, 411 subjects (n=43-50 per group) with T2D were exposed. Participants (male/female 65/35%; HbA<sub>1c</sub> (mean±SD) 8.1±0.8%; body weight 87.5±13.8 kg; diabetes duration 2.6±3.1 years; met only/diet & exercise alone 80/20%) received sc injection of one of five semaglutide doses (0.1-1.6 mg) OW, open label liraglutide (1.2 mg, 1.8 mg) OD or placebo OW. Two semaglutide doses were titrated (T) in weekly increments of 0.4 mg. Primary endpoint was change in HbA<sub>1c</sub> from baseline. Secondary efficacy endpoints included proportion of subjects reaching ADA HbA<sub>1c</sub> target (<7%) and change in body weight. Change and percentage to target were analysed by ANOVA and logistic regression, respectively. Comparisons between semaglutide and liraglutide were not multiplicity-corrected.

**Results:** Semaglutide ≥0.2 mg dose dependently reduced HbA<sub>1c</sub> from baseline (Fig), and increased the likelihood of achieving HbA<sub>1c</sub> <7% ( $p<0.05$  vs placebo for doses ≥0.2 mg). Treatment with semaglutide ≥0.8 mg numerically brought more patients to target than liraglutide 1.8 mg (0.8 mg T 69%, 0.8 mg 73%, 1.6 mg T 81% vs liraglutide 1.8 mg 57%). Body weight was dose dependently reduced from baseline by up to 4.8 kg vs placebo 1.2 kg ( $p<0.01$  for doses ≥0.8 mg). There were no reports of pancreatitis or treatment-related changes in blood calcitonin. Proportion of subjects with nausea and vomiting increased with dose, but events were generally mild or moderate and ameliorated by titration. Withdrawals due to gastrointestinal AEs were: placebo 0%; liraglutide 1.2 mg 2.2%, 1.8 mg 10%; semaglutide 0.1 mg 0%, 0.2 mg 4.7%, 0.4 mg 8.3%, 0.8 mg T 18.6%, 0.8 mg 14.3%, and 1.6 mg T 27.7%. Few subjects reported minor hypoglycaemia (semaglutide n = 5, liraglutide n = 3); no major hypoglycaemia. Injection site reactions were reported by 7 subjects: semaglutide n = 2; liraglutide n = 5. One subject (semaglutide 1.6 mg T) developed low titre non-neutralising anti-semaglutide antibodies (no crossreaction to native GLP-1).

**Conclusion:** Over 12 weeks, semaglutide dose dependently reduced HbA<sub>1c</sub> and body weight, with higher doses being more effective than liraglutide. No semaglutide safety concerns were identified. Future trials will attempt to further reduce side effects with effective dose escalation regimens.

### Efficacy and safety of once-daily lixisenatide in type 2 diabetes insufficiently controlled with basal insulin ± metformin: GetGoal-L study

R. Aronson<sup>1</sup>, M. Riddle<sup>2</sup>, P. Home<sup>3</sup>, M. Marre<sup>4</sup>, E. Niemoeller<sup>5</sup>, L. Ping<sup>6</sup>, J. Rosenstock<sup>7</sup>

<sup>1</sup>LMC Endocrinology Centres, Toronto, Canada, <sup>2</sup>Oregon Health and Science University, Portland, USA, <sup>3</sup>Newcastle University, Newcastle upon Tyne, UK, <sup>4</sup>Université Paris 7, INSERM U695, France, <sup>5</sup>Sanofi-Aventis Deutschland GmbH, Frankfurt, Germany, <sup>6</sup>Sanofi, Bridgewater, USA, <sup>7</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA.

**Background and aims:** This study used a randomized, placebo-controlled, double-blind, multicentre study design over 24 weeks to evaluate the benefit of adding once-daily lixisenatide to established and stable basal insulin therapy ± metformin, in people with Type 2 diabetes mellitus (T2DM) and inadequate blood glucose control.

**Materials and methods:** The modified intention-to-treat (mITT) population included 493 participants randomized 2:1 to injectable lixisenatide 20 µg or placebo each morning. Insulin dosage was kept constant throughout the study, within 20% of the daily dose at screening. If HbA<sub>1c</sub> was ≤7.5% at entry, insulin could be temporarily reduced by 20%. The primary endpoint was HbA<sub>1c</sub> reduction with lixisenatide versus placebo at endpoint (Week 24 or last observation carried forward).

**Results:** Baseline demographics: mean T2DM duration 12.5 years, BMI 32.1 kg/m<sup>2</sup>, HbA<sub>1c</sub> 8.4% and were balanced between both groups. Previous insulin therapy (mean 55 U/day) included glargine (50%), NPH (40%), detemir (9%), premix (2%). Compared with placebo, lixisenatide reduced HbA<sub>1c</sub> (-0.36%; p<0.001), 2-h postprandial glucose after standardized breakfast (-3.81 mmol/L; p<0.0001), and weight (-1.28 kg; p<0.0001) (Table). More lixisenatide versus placebo patients achieved HbA<sub>1c</sub> <7.0% (28 vs 12%; p<0.0001). However, insulin dose at endpoint decreased more with lixisenatide versus placebo (-5.6 vs -1.9 U/day; p=0.012). Incidences of all and serious adverse events were 73.5 and 3.7% with lixisenatide versus 68.3 and 4.2% with placebo. Discontinuation due to adverse events (mainly gastrointestinal) was 7.6% with lixisenatide and 4.8% with placebo. Comparable proportions of lixisenatide versus placebo participants had a documented hypoglycaemic event (27.7 vs 21.6%); four (1.2%) had severe hypoglycaemia with lixisenatide, none with placebo.

**Conclusion:** In patients with uncontrolled T2DM using basal insulin ± metformin, addition of once-daily lixisenatide therapy produced improved glycaemic control (despite ~10% reduction in insulin dose) and reduced body weight. Adverse events were mainly gastrointestinal and tended to subside over time.

Efficacy parameters in mITT population		Lixisenatide (n=327)	Placebo (n=166)

### Exenatide once weekly resulted in sustained improvement in glycaemic control with weight loss through four years

D. Maggs, L. Porter, Y. Li, R. Pencek, J. Zhou, C. Schulteis, L. MacConell; Amylin Pharmaceuticals, Inc., San Diego, USA.

**Background and aims:** In the 30-wk, randomised, open-label DURATION-1 study, the once-weekly formulation of the GLP-1 receptor agonist exenatide (EQW) significantly reduced HbA<sub>1c</sub> compared with twice-daily exenatide (LS mean Δ HbA<sub>1c</sub>: -1.9% vs. -1.5%; p=0.002), with similar weight loss, in 295 intent-to-treat (ITT) patients with Type 2 diabetes mellitus treated with diet/exercise, metformin, sulphonylurea (SU), and/or thiazolidinedione. Following the controlled period of the study, long-term efficacy and safety were evaluated in an open-label extension period, during which all subjects received EQW, for a total of 4 years.

**Materials and methods:** Of the original 295 ITT patients participating in DURATION-1, 258 (87%) received EQW in the long-term extension period. Of those participating in the extension, 176 (68%) patients completed 4 y of EQW treatment (baseline [mean±SD]: HbA<sub>1c</sub> 8.2±0.9%; FPG 9.2±2.3 mmol/L; weight 100±18 kg; duration of diabetes 7±5 y). During the extension period, some patients increased or decreased oral antidiabetes medication doses.

**Results:** Long-term EQW treatment was associated with significant HbA<sub>1c</sub> reduction (LS mean [95%CI]: -1.7% [-1.9, -1.5]). At 4 y, mean±SE HbA<sub>1c</sub> was 6.9±0.1%, with 55% of patients achieving HbA<sub>1c</sub> <7.0% and 36% achieving HbA<sub>1c</sub> ≤6.5%. Clinically significant improvements in FPG (-2.1 mmol/L [-2.4, -1.7]) and weight (-2.5 kg [-3.8, -1.2]) were observed. A total of 34% and 22% patients achieved the goal of HbA<sub>1c</sub> <7% and ≤6.5%, respectively, accompanied by weight loss and with no reported hypoglycaemia events. Improvements were also observed from baseline to 4 y in cardiovascular risk markers: systolic blood pressure (LS mean [95%CI]: -1.6 mmHg [-4.0, 0.9]), total cholesterol (-0.28 mmol/L [-0.43, -0.13]), LDL cholesterol (-0.21 mmol/L [-0.33, -0.08]), and triglycerides (-13% [-19, -6]; geometric LS mean % change). Nausea, the most common adverse event (AE) with EQW during the initial controlled period, decreased in incidence with ongoing therapy, as did injection-site pruritus, the most frequent injection-site related adverse event observed during the controlled period. The annual event rate for nausea with EQW was 15/100 y patient exposure over the 4-y study duration. Injection-site pruritus occurred at an annual event rate of 6/100 y patient exposure over the 4-y study duration. Six (2%) EQW patients withdrew due to gastrointestinal AEs and 1 (<1%) EQW patient withdrew due to an injection-site related adverse event over 4 y. No major hypoglycaemia was observed. Among EQW patients using SU at baseline, minor hypoglycaemia was observed at an annual event rate of 137/100 y patient exposure over 4 y. In EQW patients not using concomitant SU at baseline, minor hypoglycaemia was observed at rate of 26/100 y patient exposure over 4 y. Annual event rates for cardiac and renal/urinary disorders were 5/100 y patient exposure and 6/100 y patient exposure, respectively, for EQW over 4 y.

**Conclusion:** Overall, longterm EQW treatment was associated with significant, sustained improvement in glycaemic control and improvements in cardiometabolic measures, with no unexpected safety findings.

### Therapy escalation options for patients failing therapy with exenatide BID + metformin or glimepiride + metformin: results from the EUREXA clinical study

B. Gallwitz<sup>1</sup>, J. Guzman<sup>2</sup>, F. Dotta<sup>3</sup>, B. Guerci<sup>4</sup>, R. Simo<sup>5</sup>, B. Basson<sup>6</sup>, A. Festa<sup>7</sup>, J. Kiljanski<sup>8</sup>, H. Sapin<sup>9</sup>, S. Chen<sup>10</sup>, M. Trautmann<sup>11</sup>, G. Scherthaner<sup>12</sup>; <sup>1</sup>Eberhard-Karls University, Tübingen, Germany, <sup>2</sup>Celaya Center for Specialist Medicine, Guanajuato, Mexico, <sup>3</sup>Policlinico Le Scotte, Siena, Italy, <sup>4</sup>Brabo Hospital & CIC, Nancy, France, <sup>5</sup>Vall d'Hebron Research Institute, Barcelona, Spain, <sup>6</sup>Lilly France, St Cyr au Mont D'Or, France, <sup>7</sup>Lilly Austria, Vienna, Austria, <sup>8</sup>Lilly Polska, Warsaw, Poland, <sup>9</sup>Lilly France, Paris, France, <sup>10</sup>Amylin Pharmaceuticals, Inc., San Diego, USA, <sup>11</sup>Lilly Deutschland, Hamburg, Germany, <sup>12</sup>Rudolfstiftung Hospital, Vienna, Austria.

**Background and aims:** Type 2 diabetes continues to progress despite therapy, and treatment options when one therapy fails remain controversial. The study aim was to examine escalation with exenatide twice daily (EXE) or glimepiride once daily (GLI) in patients with metformin (MET) failure, and subsequent escalation when these agents failed to maintain HbA<sub>1c</sub> control.

**Materials and methods:** In a long-term (up to 54 mo) randomised open-label study, the primary comparison was EXE (N=490) vs GLI (N=487) as add-on for patients (mean age 56 y, BMI 32.5 kg/m<sup>2</sup>, diabetes duration 6 y, HbA1c 7.4%) with inadequate glycaemic control with MET. Primary endpoint was time to inadequate HbA1c control (HbA1c >9% at any visit or >7% at 2 successive visits, excluding first follow-up visit). Patients with inadequate control were recruited to an extension phase: patients on EXE were re-randomized to add-on GLI (EXE+GLI) or thiazolidinedione (EXE+TZD); patients on GLI received add-on EXE (GLI+EXE).

**Results:** Estimated hazard ratio for time to inadequate control (EXE/GLI Cox regression adjusted for baseline HbA1c) was 0.748 (95% CI 0.623, 0.899,  $P=0.002$ ), indicating superiority of EXE. Rate of documented hypoglycaemia (hypo) was lower for EXE vs GLI (0.76 vs 2.43 episodes/y). Data for patients who received extension add-on therapy after inadequate control on EXE or GLI are shown in Table. HbA1c decreased for EXE+TZD and increased for EXE+GLI, with significant difference from 18 mo to at least 30 mo. HbA1c decreased for GLI+EXE. BMI was unchanged for EXE+GLI and increased for EXE+TZD (difference significant from 24 mo onwards) and decreased for GLI+EXE. Rate of documented hypo was lowest in the EXE+TZD group ( $P<0.001$  vs EXE+GLI).

**Conclusion:** In EUREXA, for patients using MET, add-on therapy with EXE was superior to GLI in maintaining long-term HbA1c control. In patients who developed inadequate HbA1c control with EXE+MET, additional TZD was effective in reducing HbA1c, with low hypo risk but increased body weight. Addition of GLI to EXE+MET did not improve HbA1c (possibly due to beta-cell failure associated with disease progression) and increased hypo risk. Addition of EXE was effective in reducing HbA1c and weight in patients failing therapy with GLI+MET although hypo was observed. These results support use of TZD but not GLI as the third therapy for HbA1c control in patients losing glycaemic control after long-term therapy with EXE+MET.

Initial randomised therapy	EXE		GLI
Extension therapy	EXE+GLI (N=74)	EXE+TZD (N=76)	GLI+EXE (N=166)
Exenatide exposure during extension (wk)	112±42	109±51	99±52
Baseline HbA1c at extension start (%)	7.59±0.55	7.74±0.68	7.67±0.77

### Long-term safety and efficacy of linagliptin as add-on therapy to basal insulin in patients with type 2 diabetes: a 52-week randomised, placebo-controlled trial

H. Yki-Järvinen<sup>1</sup>, J. Rosenstock<sup>2</sup>, S. Durán-García<sup>3</sup>, S. Pinnett<sup>4</sup>, S. Bhattacharya<sup>4</sup>, S. Thiemann<sup>5</sup>, S. Patel<sup>6</sup>, H.-J. Woerle<sup>5</sup>;

<sup>1</sup>Dept of Medicine, Helsinki, Finland, <sup>2</sup>Dallas Diabetes and Endocrine Center, Dallas, USA, <sup>3</sup>Valme University Hospital Medical School, Seville, Spain, <sup>4</sup>Boehringer Ingelheim, Biberach, Germany, <sup>5</sup>Boehringer Ingelheim, Ingelheim, Germany, <sup>6</sup>Boehringer Ingelheim, Bracknell, UK.

**Background and aims:** Titrated basal insulin added to metformin +/- pioglitazone improves glucose control close to glycaemic targets in patients with type 2 diabetes. Adding a DPP-4 inhibitor instead of a sulphonylurea to further improve glucose control is a sensible therapy option to avoid hypoglycaemia and weight gain. This multicentre, randomised, placebo-controlled, Phase 3 study evaluated the long-term safety and efficacy of the DPP-4 inhibitor linagliptin as add-on therapy to basal insulin alone or in combination with metformin and/or pioglitazone. The primary efficacy endpoint - mean change in HbA1c from baseline to Week 24 - was reported recently. Here we

report sustained glucose control and long-term safety data with an emphasis on hypoglycaemia.

**Materials and methods:** A total of 1261 patients inadequately controlled on insulin glargine, insulin detemir, or NPH insulin were randomised to receive linagliptin 5 mg qd or placebo (1:1) for at least 52 weeks. The background dose of basal insulin was kept stable up to 24 weeks but could be freely adjusted after this period.

**Results:** Mean ± SD baseline characteristics were similar in the linagliptin vs placebo groups: age, 59.7 ± 9.9 vs 60.4 ± 10.0 yrs; BMI, 30.8 ± 5.4 vs 31.2 ± 5.0 kg/m<sup>2</sup>; HbA1c, 8.3% ± 0.9% both; basal insulin dose, 42 ± 32 vs 40 ± 27 IU/day. Mean exposure to study medication exceeded 52 weeks and was comparable in both groups: linagliptin 435 days; placebo 422 days. Overall safety and tolerability for linagliptin was similar to placebo. The proportion of patients with ≥1 adverse event (AE) was slightly lower with linagliptin (78.4%) compared with placebo (81.4%) and most AEs were of mild or moderate intensity. The incidence of hypoglycaemia (Figure A) was similar in both groups (linagliptin 31.4%; placebo 32.9%) despite better glycaemic control with linagliptin, and the number of severe hypoglycaemic events was low (linagliptin 1.7%; placebo 1.1%). Mean ± SD change in body weight was minimal and comparable between the treatment groups (linagliptin -0.30 ± 3.7 kg; placebo -0.04 ± 3.1 kg). The placebo-adjusted mean ± SE change in HbA1c from baseline at Week 52 for linagliptin (Figure B) was -0.53% ± 0.05 (full analysis set;  $P<0.0001$ ). This was accompanied by a mean ± SE change in basal insulin dose up to Week 52 of +2.6 ± 0.8 IU/day for linagliptin vs +4.2 ± 0.8 IU/day for placebo ( $P<0.003$ ).

**Conclusion:** The addition of linagliptin to patients inadequately controlled on non-optimized basal insulin therapy significantly improves long-term glycaemic control over 52 weeks with no additional risk of hypoglycaemia and no weight gain.

## OP 02 Impact of bariatric surgery

7

### Reversal of type 2 diabetes following gastric bypass surgery is determined by the degree of achieved weight loss and is not limited by disease duration

S. Steven<sup>1</sup>, J.-A. Coates<sup>2</sup>, P. Ogilvie<sup>2</sup>, P.E. Carey<sup>2</sup>, P.K. Small<sup>3</sup>, R. Taylor<sup>1</sup>;<sup>1</sup>Magnetic Resonance Centre, Newcastle University, Newcastle upon Tyne,<sup>2</sup>Metabolic Medicine Unit, Sunderland Royal Hospital, <sup>3</sup>Department of Surgery, Sunderland Royal Hospital, UK.

**Background and aims:** Bariatric surgery is currently the most effective tool to reverse type 2 diabetes. Roux-en-Y gastric bypass is now the most common procedure worldwide. It is widely believed that long duration type 2 diabetes results in an irreversible decline in beta cell function and previous studies have suggested that long duration diabetes is less likely to revert to normal after bariatric surgery. However, these data may have been confounded by the inclusion of individuals with alternative diagnoses to type 2 diabetes, such as MODY or slow onset type 1 diabetes. We have previously demonstrated the pathophysiological mechanism of diabetes reversal following acute food restriction. The aim of this study was to define the influence of diabetes duration and achieved weight loss on reversal of type 2 diabetes.

**Materials and methods:** Data were collated on consecutive referrals to the diabetes team at a specialist bariatric surgery centre (2009–2011). 92 individuals with type 2 diabetes underwent Roux-en-Y gastric bypass surgery. The diagnosis of type 2 diabetes was verified in all individuals. Reversal of diabetes was defined as achieving a post-operative HbA<sub>1c</sub> of <6.1% or 43 mmol/mol. Diabetes duration was defined as short (<4 years) or long (>8 years). Follow-up information on use of anti-diabetic medications was requested from general practitioners. Results are expressed as mean ± SD or median and range when not normally distributed. Two sample t-test and Spearman rank sum were tested using Minitab 15 Statistical Software.

**Results:** 34 males and 58 females were identified; age 49.1 ± 9.2 years, pre-operative BMI 47.3 kg/m<sup>2</sup> (34.8–78.2) and HbA<sub>1c</sub> 7.1% (5.3–14.0). Median diabetes duration at the time of surgery was 5 years (1 month–22 years). Prior to surgery, diabetes treatments were: metformin (76); sulphonylurea (32); insulin (18); thiazolidinedione (16); glucagon-like peptide-1 agonist (15); dipeptidyl peptidase-4 inhibitor (6). Diabetes reversal occurred in 79% of those with short duration disease and 38% of those with long duration disease. Of these, 85% and 86% respectively (with available follow-up data) were confirmed to be off anti-diabetic medications. Post-operative decrease in BMI was the major predictor of diabetes reversal: <10 kg/m<sup>2</sup>: 53%; 10–15 kg/m<sup>2</sup>: 74%; and >15 kg/m<sup>2</sup>: 82% reversal. The achieved post-operative HbA<sub>1c</sub> correlated with the percentage body weight loss (Rs = -0.293; p-value = 0.008) and also the absolute weight loss (Rs = -0.307; p-value = 0.006). In those achieving weight loss of more than 20% of initial body weight, the reversal rates in the short and long diabetes duration groups were 87% and 56% compared to 70% and 25% in those achieving less than 20% weight loss. In the long duration group, the mean weight loss in those who reversed (median duration 11 years, range 10–18) was 34.5 ± 13.4 kg compared to 21.5 ± 9.4 kg in those who did not reverse (median duration 12 years, range 9–19) (T-value = 2.4; p-value = 0.035).

**Conclusion:** Duration of type 2 diabetes is no bar to reversal of type 2 diabetes, and long duration disease can be reversed by Roux-en-Y gastric bypass surgery. The degree of achieved weight loss is the main determinant of outcome. Individuals with long duration disease require greater weight loss in order to reverse type 2 diabetes.

8

### Insulin resistance in femoral bone marrow fat of diabetic morbidly obese patients is alleviated after bariatric surgery

T.T. Pham<sup>1</sup>, R. Kiviranta<sup>2</sup>, J.C. Hannukainen<sup>1</sup>, H. Immonen<sup>1</sup>, P. Salminen<sup>3</sup>, P. Nuutila<sup>1,4</sup>;<sup>1</sup>Department of Medicine, Turku PET center, <sup>2</sup>Department of Medicine, Department of Medical Biochemistry and Genetics, <sup>3</sup>Department of Surgery, Turku University Hospital, <sup>4</sup>Department of Medicine, Turku University Hospital, Turku, Finland.

**Backgrounds and aims:** In adults, majority of bone marrow space of long bones is filled with fat tissue. Obesity is linked to increased bone marrow adiposity and insulin resistance. We have recently found that glucose uptake (GU) in femoral bone marrow fat is responsive to insulin. Our aim in this

study was to measure glucose uptake in femoral and vertebral bone marrow during fasting and hyperinsulinemic euglycemic clamp in morbidly obese and type 2 diabetes patients. Further, we tested whether bariatric surgery would alter bone marrow glucose uptake.

**Materials and methods:** Twenty-three morbidly obese patients (BMI 42.6 ± 3.5 kg/m<sup>2</sup>), 9 non-diabetics and 14 with prediabetes or type 2 diabetes (DM), were studied before and 6 months after bariatric surgery. GU in muscle, subcutaneous and visceral fat, and vertebral and femoral bone marrow was measured with <sup>18</sup>F-FDG and Positron Emission Tomography (PET) at fast and during hyperinsulinemic euglycemic clamp (1 mU/kg/min) before and 6 months after the bariatric surgery.

**Results:** Obese patients were similarly insulin resistant in skeletal muscle and whole body before the operation. At fasting state, GU in femoral bone (8.7 ± 3.2 μmol/l/min) was similar to muscle and visceral GU and 2.5 times higher than subcutaneous fat. Insulin increased femoral bone marrow adipose GU by 90% in obese without DM (to 16 ± 1 μmol/kg/min, p = 0.02), but not in those with DM. Vertebral bone marrow GU was high already at baseline (26.4 ± 4.5 μmol/l/min) and not altered by insulin. After the operation, patients lost weight by 27.5 ± 5.2 kg (p < 0.001) and improved whole body insulin sensitivity (DM+ by 119 %, DM- by 81 %, p < 0.001, NS between subgroups). Femoral bone GU responded to insulin postoperatively by 134% (p = 0.03) and 187% (p = 0.001) in non-DM and DM patients.

**Conclusion:** This study shows that fatty femoral bone marrow is one site of insulin resistance in patients with type 2 diabetes and obesity, while vertebral bone marrow consisting mostly of hematopoietic cells is not. Femoral bone adipose tissue insulin resistance is reversed 6 months after bariatric surgery. Further studies are needed to assess the effects of insulin sensitizers and high daily insulin dosage on bone adipose metabolism.

### Glycaemic control after endoscopically placed duodenal-jejunal bypass liner in patients with type 2 diabetes and body mass index between 25 and 35 kg/m<sup>2</sup>

D.J. Pournaras<sup>1</sup>, R.V. Cohen<sup>2</sup>, C.W. le Roux<sup>1</sup>, D. Papamargaritis<sup>1</sup>, J. Salles<sup>2</sup>, T. Petry<sup>2</sup>, J. Correa<sup>2</sup>, M.G. Neto<sup>2</sup>, B. Martins<sup>2</sup>, P. Sakai<sup>2</sup>, C.A. Schiavon<sup>2</sup>, C. Sorli<sup>3</sup>;<sup>1</sup>Imperial Weight Center, Imperial College London, UK, <sup>2</sup>Center of Excellence for the Surgical Treatment of Morbid Obesity, Hospital Oswaldo Cruz, São Paulo, Brazil, <sup>3</sup>Billings Clinic, Billings, USA.

**Background and aims:** The duodenal-jejunal bypass liner (DJBL, EndoBarrier™, GI Dynamics Inc., Lexington, MA) is a removable device which is endoscopically placed. It was designed with the objective to mimic the effects of the bypass of the proximal gut in the Roux-en-Y gastric bypass and Duodenal Jejunal Bypass without the risks associated with surgery. The aim of this study was to investigate the effect of this novel device on glycemic control outcomes and explore its mechanism of action.

**Materials and methods:** Sixteen patients with type 2 diabetes and BMI < 35 kg/m<sup>2</sup> were included in this study. Time points were before and one, 12 and 52 weeks after implantation of the device. A standard mixed meal test was given and blood samples were collected prior to and 30, 60, 90 and 120 minutes after the meal. Glucose, insulin and C-peptide were measured. Insulin sensitivity was calculated using the Matsuda Index and the Homeostatic Model of Assessment Insulin Resistance (HOMA-IR). Insulin secretion was calculated using fasting and total insulin secretion rate after the meal by deconvolution of C-peptide concentrations. First phase insulin release was estimated by the acute insulinogenic index.

**Results:** One year post implantation, BMI, HbA<sub>1c</sub>, fasting and 120 min glucose levels were reduced (all p < 0.001). Insulin sensitivity as measured by the Matsuda Index and HOMA-IR improved significantly as early as 1 week post-implantation (p < 0.01). Fasting (p = 0.053) and area under the curve (p = 0.13) insulin, fasting (p = 0.28) and area under the curve C-peptide (p = 0.31), fasting (p = 0.27) and total (p = 0.81) insulin secretion rate, and insulinogenic index (p = 0.43) remained unchanged over the one year period of the implantation of the device.

**Conclusion:** Implantation of DJBL leads to improved glycemic control in overweight and obese type 2 diabetic patients due to improved insulin sensitivity observed in the early post implantation period and is sustained over one year. DJBL has no effect on insulin production.

## 10

**Glucagon-like-peptide-1 (GLP-1) is important for the improved beta cell function in type 2 diabetic subjects after Roux-en-Y gastric bypass (RYGB)**N.B. Jorgensen<sup>1,2</sup>, C. Dirksen<sup>1</sup>, S.H. Jacobsen<sup>1</sup>, K.N. Bojsen-Møller<sup>1</sup>, D.L. Hansen<sup>1</sup>, D. Worm<sup>1</sup>, S. Madsbad<sup>1</sup>, J.J. Holst<sup>2,3</sup><sup>1</sup>Dep. of Endocrinology, Hvidovre Hospital, <sup>2</sup>Dept of Biomedical Science, University of Copenhagen, <sup>3</sup>Novo Nordisk Foundation Centre for Basic Metabolic Research, University of Copenhagen, Denmark.

**Background and aims:**  $\beta$  cell function is known to improve in type 2 diabetic (T2D) subjects after RYGB, but whether this is explained by an increased GLP-1 secretion is not known. We used the GLP-1 receptor specific blocker, exendin (9-39) (EX9), to evaluate the role of GLP-1 on post RYGB  $\beta$  cell function.

**Materials and methods:** A liquid meal test was performed on two separate days before and 1 wk and 3 mo after RYGB in 7 subjects with T2D scheduled for RYGB surgery (Age:  $48.6 \pm 4.3$ ; BMI:  $36.9 \pm 0.77$  kg/m<sup>2</sup>). Fasting blood samples were drawn followed by a bolus-infusion of EX9 (900 pmol/kg/min) or isotonic saline (NaCl). The order of EX9 and NaCl infusion was randomized. After 30 min of infusion, the meal was ingested over 30 min, and blood was sampled frequently from 30 min before to 4 h after meal start. Prehepatic insulin secretion rates (ISR) were calculated by deconvolution of peripheral C-peptide concentrations and the application of population based parameters for C-peptide kinetics using the ISEC software.  $\beta$ -cell glucose sensitivity ( $\beta$ -GS) was calculated by cross correlating ISR and the corresponding glucose concentrations, and this was used for characterizing  $\beta$ -cell function.

**Results:** After RYGB fasting P-glucose (pre:  $8.5 \pm 0.94$  mM, 1 wk:  $7.0 \pm 0.57$  mM ( $p=0.08$ ), 3 mo:  $6.1 \pm 0.3$  mM ( $p<0.05$ ) and S-insulin ( $127 \pm 17$  pM,  $66 \pm 4$  pM ( $p<0.05$ ),  $59 \pm 7$  pM ( $p<0.05$ )) decreased. HOMA-IR was halved after RYGB ( $6.5 \pm 0.6$ ,  $3.0 \pm 0.4$  ( $p<0.05$ ),  $2.3 \pm 0.3$  ( $p<0.05$ )) and did not differ between the day of EX9 infusion and the day of NaCl infusion neither pre nor 1 wk nor 3 mo post RYGB. Before RYGB the area-under the glucose curve (AUC) was  $2.3 \pm 0.2$  M $\cdot$ min and this had decreased to  $1.9 \pm 0.1$  M $\cdot$ min ( $p=0.08$ ) 1 wk and to  $1.7 \pm 0.1$  M $\cdot$ min ( $p<0.05$ ) 3 mo after the operation. EX9 caused AUC glucose to increase before and after RYGB ( $2.7 \pm 0.3$  M $\cdot$ min ( $p<0.05$ ),  $2.4 \pm 0.2$  M $\cdot$ min ( $p<0.05$ ),  $2.1 \pm 0.1$  M $\cdot$ min ( $p<0.05$ )).  $\beta$ -GS increased after RYGB on the days of NaCl infusion ( $1.1 \pm 0.3$  pmol/kg/mM,  $2.3 \pm 0.3$  pmol/kg/mM ( $p<0.01$ ),  $2.3 \pm 0.5$  pmol/kg/mM ( $p<0.05$ )). Compared to the corresponding day of NaCl infusion, EX9 infusion caused  $\beta$ -GS to decrease only after RYGB ( $0.9 \pm 0.2$  pmol/kg/mM ( $p=0.2$ ),  $1.2 \pm 0.3$  pmol/kg/mM ( $p<0.01$ ),  $1.1 \pm 0.3$  pmol/kg/mM ( $p<0.05$ )), to levels not different from the preoperative  $\beta$ -GS.

**Conclusion:** After RYGB glucose tolerance and beta-cell function is improved in type 2 diabetic subjects. Infusion of a GLP-1 receptor specific blocker causes beta-cell function to decrease to preoperative levels, and glucose tolerance to impair during a meal test. This suggests an important role for GLP-1 in the improved glucose metabolism of T2D patients after RYGB

**Oral route versus gastrostomy route: effects on glucose metabolism and incretin response to a mixed meal in gastric-bypassed humans**A. Lindqvist<sup>1</sup>, M. Ekelund<sup>2</sup>, J. Hedenbro<sup>2</sup>, L. Groop<sup>1</sup>, N. Wierup<sup>1</sup><sup>1</sup>Clinical Sciences, Malmö, <sup>2</sup>Dept. of Surgery, Lund, Sweden.

**Background and aims:** Gastric bypass surgery (GBP) has beneficial effects on Type 2 diabetes (T2D), often resulting in a rapid normalization of blood glucose. The mechanisms behind the resolution of T2D after GBP remain unclear. Two hypotheses predominate; the foregut and the hindgut theories. The foregut theory states that the resolution of T2D is dependent on anti-incretins produced in the stomach and duodenum in response to nutrients. GBP prevents nutrient-stimulated anti-incretin stimulation, and incretins are allowed to work unopposed. The hindgut theory states that the rapid delivery of undigested nutrients to more distal parts of the intestine leads to up-regulation of the production of L-cell derived hormones, such as GLP-1. In this study, we aimed at exploring the role of the foregut in glucose tolerance and incretin response to a mixed meal in gastric-bypassed humans. We utilized a model where a gastrostomy tube (GT) was placed in the stomach. Infusing a mixed meal via the GT allowed us to study presurgical exposure to nutrients under conditions of postsurgical caloric restriction (weight loss).

**Materials and methods:** Four female patients having previously undergone GBP with an accompanying gastrostomy tube were given a mixed meal test orally, and thereafter the same amount of the test meal was infused via the GT. Blood was collected at regular intervals before and after the mixed meals. Glucose, insulin, glucagon, glucose-dependent insulintropic peptide (GIP) and glucagon-like peptide 1 (GLP-1) were analyzed in serum or plasma.

**Results:** The oral administration route resulted in a robustly larger insulin response, compared to the GT route, at 5, 10, 15 and 30 minutes after the mixed meal (57%, 210%, 368%, 359% and 193%, respectively). Serum glucose was elevated at 5, 10, 15 and 30 minutes after oral ingestion of the mixed meal (10%, 10%, 23% and 14%, respectively, compared to GT infusion). Plasma glucagon was higher at 30 minutes after oral ingestion of the mixed meal (17% compared to GT infusion of the mixed meal). Insulin AUC:GLP-1 AUC-ratio was 2-fold higher when mixed meal was administered orally compared to mixed meal infused via the GT. Administering the mixed meal orally resulted in a 2-fold increase in Insulin AUC:GIP AUC compared to mixed meal infused via the GT (\*,  $p<0.05$ ).

**Conclusion:** In GBP patients, oral administration of a mixed meal triggered a higher response in insulin and GIP than did infusion via the GT. Whether this is due to the bypassing of the cephalic phase when administering the mixed meal via the GT route or the possibility that the secretory pattern of candidate anti-incretins in the proximal part of the intestine and the stomach may have been altered as a result of the gastric bypass surgery remain to be elucidated. In summary, the oral administration route evokes a more rapid and robustly larger insulin and incretin response than does the GT infusion. Thus, a rapid delivery to the hindgut may be of importance when considering the underlying mechanisms of the beneficial aspects of GBP on glucose metabolism.

**Does diabetes status affect hypertension resolution after bariatric surgery?**L. Flores<sup>1,2</sup>, J. Vidal<sup>1,2</sup>, S. Canivell<sup>3</sup>, L. Rodriguez<sup>1</sup>, E. Esmatjes<sup>4,3</sup><sup>1</sup>Obesity Unit, Hospital Clinic, <sup>2</sup>CIBERDEM <sup>3</sup>IDIBAPS, Hospital Clinic, Barcelona, <sup>4</sup>Diabetes Unit, Hospital Clinic, Barcelona, Spain.

Bariatric surgery is the most effective treatment for significant and sustained weight loss. On the other hand, weight loss is the main non-pharmacological therapy to control blood pressure in hypertensive-obese subjects. However, it has been demonstrated that less weight is lost in diabetic subjects after bariatric surgery (BS). The aims of this study were to evaluate the predictive factors associated with the risk of persistent hypertension and determine whether diabetes status affects hypertension resolution in a cohort of hypertensive-obese subjects after BS.

**Methods:** Weight, height, waist circumference and blood pressure were determined with standardized procedures. The body mass index (BMI), excess body weight (EBW) and EBW loss were calculated.

**Results:** We evaluated 530 patients undergoing BS between 2007-2009: 264 (50%) were hypertensive-obese (defined as having permanent antihypertensive treatment or office blood pressure  $\geq 140/90$  mmHg prior to bariatric surgery), 88 (33%) of whom had diabetes. Before BS older age, male gender and greater waist circumference differentiated hypertensive-obese from normotensive patients. Among all the hypertensive-obese subjects, the prevalence of hypertension significantly fell to 33% ( $p<0.05$ ) at 12 months after BS. Logistic regression models were constructed by gender to assess the variables associated with the risk of persistent hypertension after BS, and showed that men  $\geq 40$  years [OR 11.7 (95% CI 2.50-54.46,  $p=0.002$ )] and the number of antihypertensive drugs used [OR 3.29 (95% CI 1.59-6.82,  $p=0.001$ )] were independently associated with the risk of persistent hypertension. In women, time since hypertension diagnosis  $>10$  years [OR 3.96 (95% CI 1.47-10.67,  $p=0.007$ )] and the number of antihypertensive drugs used [OR 1.86 (95% CI 1.06-3.29,  $p=0.03$ )] were associated with the risk of persistent hypertension. Pre-surgical BMI, waist circumference, EBW, EBW loss and the type of surgical technique (gastric bypass or sleeve gastrectomy) were not significant predictors of persistent hypertension. The results were similar after excluding patients with diabetes, and EBW loss did not affect hypertension resolution in non diabetic patients.

**Conclusion:** BS is associated with a high rate of hypertension resolution, with older age, longer hypertension duration and severity of hypertension being predictors of hypertension persistence after BS. Diabetes status did not affect hypertension resolution.

#### Mannose-binding lectin level and cerebral white matter lesions in type 2 diabetes

P. Hoyem<sup>1</sup>, E. Laugesen<sup>1</sup>, S. Thrysoe<sup>2</sup>, U. Kampmann<sup>1</sup>, B. Stausbol-Gron<sup>2</sup>, M. Bjerre<sup>1</sup>, J.S. Christiansen<sup>1</sup>, W.Y. Kim<sup>2</sup>, T.K. Hansen<sup>1</sup>;

<sup>1</sup>Department of Endocrinology and Internal Medicine MEA, Denmark,

<sup>2</sup>MR Research Centre, Aarhus University Hospital, Aarhus, Denmark.

**Background and aims:** Mannose-binding lectin (MBL) serum levels are mainly genetically determined and in diabetes high levels are known to be associated with increased risk of a number of diabetic complications. Cerebral white matter lesions (WMLs), especially confluent WMLs, are associated with risk of cerebral infarction, a well-known diabetic complication. We examined the impact of MBL levels on WMLs assessed by magnetic resonance imaging (MRI) to further evaluate MBL as a prognostic and pathogenetic factor in diabetic complications.

**Materials and methods:** In a cross-sectional setting we included 100 patients with type 2 diabetes and time since diagnosis < 5 years (median age 59 years; males 52%), and 100 non-diabetic sex- and age-matched controls. We measured serum MBL and performed brain MRI. MRIs were subsequently qualitatively graded regarding WMLs from 0 to 2 on the Breteler-scale (0-4 punctate WMLs=0, >4 punctate WML but no confluent WMLs=1, presence of confluent WMLs regardless of number of punctate WMLs=2) by a trained radiologist blinded to participants status.

**Results:** Median MBL was 643 µg/L (inter-quartile range (IQR) 246-1419 µg/L) in patients and 798 µg/L (IQR 262-1667 µg/L) in controls, no difference between groups ( $P=0.52$ ). MBL correlated significantly to age (Spearman correlation,  $\rho=0.17$ ,  $P=0.02$ ), and was higher among men ( $P=0.007$ ), but was not related to duration of diabetes ( $P=0.16$ ). Distribution of Breteler score (0/1/2) was 59%/30%/11% among patients vs. 54%/32%/14% among controls ( $P=0.73$ ), and there was no difference in distribution between sexes. For all participants with MBL below median the distribution of Breteler score was 62%/32%/6% vs. 51%/31%/18% for all participants with MBL above median, the distributions differed significantly (Chi-Square  $p=0.03$ ), but the distribution did not differ significantly within groups (Chi-Square patients  $P=0.26$  and controls  $P=0.11$ ). Participants with confluent WMLs (Breteler score 2) had significantly higher median level of MBL 1174 µg/L (IQR 584-1698 µg/L) than participants without confluent WMLs (Breteler score 0+1) 626 µg/L (IQR 246-1545 µg/L) ( $P=0.02$ ), which was not the case within groups (patients  $P=0.19$ , controls  $P=0.07$ ).

**Conclusion:** In summary high serum MBL are significantly associated with the presence of WMLs in a mixed cohort of newly-diagnosed type 2 diabetic patients and non-diabetic control subjects. This association did not apply for the patient group, which could be expected as high MBL levels are known to be significantly associated with the risk of other diabetic complications. The missing association might be due to lack of power or to the short duration of diabetes.

#### Acute hyperglycaemia impairs working memory in women without diabetes but not in women with type 2 diabetes

A. Backeström<sup>1</sup>, T. Olsson<sup>2</sup>, S. Eriksson<sup>3</sup>, L. Nyberg<sup>4</sup>, L.-G. Nilsson<sup>5</sup>, O. Rolandsson<sup>1</sup>;

<sup>1</sup>Public Health and Clinical Medicine, Family Medicine, Umeå, <sup>2</sup>Public Health and Clinical Medicine, Medicine, Umeå, <sup>3</sup>Community Medicine and Rehabilitation, Geriatrics, Umeå, <sup>4</sup>Integrative Medical Biology, Radiation Sciences, Umeå, <sup>5</sup>Psychology, Stockholm, Sweden.

**Background and aims:** Metabolic dysfunction including type 2-diabetes is associated with increased risk for cognitive decline. Notably, it is debated whether acute hyperglycemia affects different brain regions and thus different memory functions. Thus, our aim was to study the effect of acute hyperglycemia on working, semantic and episodic memory in patients with type 2-diabetes (T2D) and non-diabetic participants (controls).

**Materials and methods:** Thirty-six (M/F, 18/18, mean±SD 66±2.3 yrs) patients with T2D and 34 (M/F, 17/17, mean age 66±0.6 yrs) controls underwent a standard hyperglycemic clamp and a placebo clamp (saline infusion) in a randomized and blinded manner with a two-week interval. Working, semantic, and episodic memory was tested at both clamps after 110 minutes by a nurse blinded to the clamp and the glycemic status of the participant. The results of the memory tests were standardized (z-scores). All participants were free from cognitive disorders, depression, CVD, or medication influencing their memory.

**Results:** T2D patients had a higher body mass index, BMI, than controls (27.9±3.5 vs. 25.5±2.6 kg/m<sup>2</sup>,  $p=0.002$ ) but there was no difference in blood pressure or educational levels. Controls had better working memory (z-score 0.26±0.79) in the placebo clamp compared to T2D (z-score -0.25±0.74,  $p=0.007$ ) while there were no differences in episodic or semantic memory. Women with T2D had poorer working memory than controls in the placebo clamp even after adjustment for BMI, fasting glucose and glucose at time for memory testing (B -0.60, SE 0.27,  $p=0.037$ ). In the hyperglycaemic clamp the working memory decreased in controls and improved in T2D which equated the difference (controls z-score 0.16±0.81 vs. T2D -0.15±0.69,  $p=0.08$ ). This pattern was driven by changes among women (placebo clamp: controls working memory 0.47±0.74 vs. T2D -0.21±0.64,  $p=0.007$ ; hyperglycaemic clamp: controls working memory 0.45±0.88 vs. T2D -0.05±0.76,  $p=0.08$ ). The majority of women in the control group (71%) impaired their working memory during the hyperglycaemic clamp compared to the placebo clamp. The opposite pattern was observed among T2D women with 61% improving their working memory in the hyperglycaemic clamp compared to the placebo clamp.

**Conclusion:** Women with T2D have a poorer working memory compared to non-diabetic women during normoglycaemic conditions. In acute hyperglycaemia the two groups show different reactions equating the difference. This suggests altered prefrontal function in women with T2D with a decreased plasticity to a metabolic change.

#### Insulin therapy in patients with type 2 diabetes mellitus during the first 24 hours of acute stroke: advantages of intravenous infusion

L.G. Strongin, I.G. Grigoryan, N.G. Belyaeva, A.V. Gustov;  
Medical Faculty, State Medical Academy, Nizhny Novgorod, Russian Federation.

**Background and aims:** Points of intravenous infusion for blood glucose control in patients with stroke and type 2 diabetes mellitus is proved at a target level less than 7 mmol/l, but for the more acceptable level 7.8-10mmol/l it is not so obvious. The comparison of the efficiency and safety of intravenous infusion with fractional subcutaneous injections was carried out in the given research.

**Materials and methods:** 73 patients with stroke and type 2 diabetes mellitus were included in the given research. Patients were subdivided in to 2 groups. In the basal group (n=36) the continuous infusion of insulin within 24 hours after the development of stroke was spent. Patients in the group of comparison (n=37) received insulin therapy in the form of subcutaneous injections. There were no differences in the baseline characteristics between groups. In both groups short-acting insulin was titrated according to glucose levels to achieve the blood glucose level between 7.8 and 10 mmol/l. The effect of therapy was estimated according to mortality and dynamics of symptoms

on National Institutes of Health Stroke Scale and Barthel Activities of Daily Living Index,

**Results:** In the basal group target glucose levels have been reached through 2(2-3)hour, in the control group in 5(3-6) hour,  $p=0.0019$ . In the group of insulin infusion 97% patients achieved the glucose targets of the study protocol, versus 71% in the control group, ( $p=0.012$ ). The mean daily glycemia was 8,7 (7,5-11,3) mmol/l in the group of infusion and 9,7(7-11,7) mmol/l in the group of comparison,  $p=0.025$ , amplitude of fluctuations of glycemia within a day was 0,95 mmol/l in the basal group and 5,3 mmol/l in the control group,  $p<0.01$ , frequency of hypoglycemia in the group of intravenous infusion was 9%, in the group of subcutaneous injections 22%,  $p=0.037$ . The total amount of insulin used within the day in the basal group was 21(13,5-43) units, in the group of comparison 48 (16-66) units,  $p<0.01$ . There were no differences in hospital mortality between the groups: in the group of intravenous infusion 25% patients died, in the group of comparison 32,4%,  $p=0.32$ . Dynamics of neurologic deficiency according to the National Institutes of Health Stroke Scale was 12 points in the basal group versus 6 points in the control group,  $p<0.01$ . The difference on Barthel Activities of Daily Living index was 45 points in the infusion group and 20 points in the control group,  $p<0.01$ .

**Conclusion:** Glucose control using continuous intravenous infusion at a target glucose level between 7,8-10 mmol/l has advantages concerning efficiency and safety over subcutaneous injections of insulin in the acute period of stroke in patients with diabetes mellitus.

## 16

**The significance of social non-amendable factors in the two-year functional outcome of ischaemic stroke male and female diabetic patients**  
K. Tzirogiannis<sup>1</sup>, V. Dragoumanos<sup>1</sup>, N. Melas<sup>2</sup>, M. Vourvou<sup>3</sup>, E. Foustieris<sup>1</sup>, A. Melidonis<sup>1</sup>;

<sup>1</sup>Diabetes Center, 'Tzanio' General Hospital, Piraeus, <sup>2</sup>1st Department of Internal Medicine, 'Tzanio' General Hospital, Piraeus, <sup>3</sup>Intensive Care Unit, 'Papageorgiou' General Hospital, Thessaloniki, Greece.

**Background and aims:** Diabetes doubles the risk of stroke recurrence and aggravates the prognosis of stroke patients. The multifactorial, regardless of gender nature of stroke etiology is also well established. Based on their susceptibility to modification, stroke risk factors are classified as amendable or non-amendable. The purpose of the present study is to evaluate and compare the effect of various non-amendable social risk factors on the two-year functional outcome of ischemic stroke (IS) male and female diabetic patients.

**Materials and methods:** The study population consisted of 312 type II Caucasian diabetic patients that suffered primary IS. Assessment was performed independently by three neurology specialists upon hospital admission and at two years after the initial episode according to NIHSS (0-42). Improvement of functional outcome was considered a decrease of at least 4 units at NIHSS. Comparisons between categorical variables were evaluated by Fisher's exact test.

**Results:** After 24 months 175 out of 312 (56.1%), 75 (24%) male and 100 (32.1%) female patients presented neurological improvement. Female patients (OR=1.81,  $p=0.009$ ), patients that cohabited with their partners (OR=2.35,  $p<0.001$ ), their children (OR=4.46,  $p<0.001$ ), or both (OR=4.61,  $p=0.001$ ) exhibited significantly better post stroke neurological outcome at two years. Divorced (OR=0.24,  $p=0.027$ ), single (OR=0.09,  $p<0.001$ ), childless (OR=0.14,  $p<0.001$ ) or single living patients (OR=0.16,  $p<0.001$ ) exhibited lower rates of neurological improvement. Contrary to male, female patients exhibited better prognosis if cohabited with partner and children (OR=4.03,  $p=0.01$ ), showed no correlation if childless (OR=0.62,  $p=0.169$ ), and worsened if divorced (OR=0.06,  $p=0.001$ ).

**Conclusion:** Married status and cohabitation with children are among the non-amendable social risk factors that confer a better two-year functional outcome in diabetic IS patients. Being single, living alone, and childlessness is connected with deteriorated post stroke prognosis. Contrary to male, female patients exhibit better neurological outcome if cohabiting with partner and children, exhibit no further improvement if childless, and worsen if divorced.

Two-year post stroke neurological improvement according to NIHSS

	Males		Females		Total	
Non amendable risk factors	OR (95% CI)	p	OR (95% CI)	p	OR (95% CI)	p
Gender (male)	N/A		N/A		0.55 (0.35-0.86)	0.009

**Diabetes mellitus type 2 and markers for stroke: 10 years, prospective study of the 1,334 cases representative cohort**

J. Taton, P. Luźniak, A. Czech, A. Wojciechowska-Luźniak;  
Chair and Department of Internal Diseases and Diabetology, Warsaw Medical University, Poland.

**Background and aims:** The morbidity and mortality due to stroke in persons with type 2 diabetes mellitus is 3-4 times higher than in the general population. Actual epidemiological studies underline the increasing tendency of these indices. The efficacy of the prevention of stroke stands up as the "hot" problem in diabetes mellitus care. It has motivated us to examine the risk of stroke in a well defined, large cohort of type 2 diabetics using a prospective study plan lasting 10 years. The specific aims of the study were : 1) determination of the incidence and mortality due to stroke in a dynamic, comparative way during 10 years , and 2) recognition of the appearance during the 10 years period of risk factors for stroke.

**Materials and methods:** The cohort of 1,334 type 2 diabetes mellitus patients was organized by allocating the patients attending the same outpatient diabetic clinic suitable for prolonged observation. Among patients were 597 males and 737 women; their average age was  $62.61 \pm 10.31$  and the diabetes mellitus duration  $9.40 \pm 6.26$  years. The main clinical determinants such as BMI, blood pressure, fasting and postprandial glycemia, cholesterol, triglycerides, creatinine, albuminuria, and also the co-existing complications of diabetes mellitus type 2 and co-morbid states, were first established at the time of the patients' entry to the study and assessed every year in the 10 years period. The clinical and laboratory parameters of the cardiac and neurological function were specifically evaluated. The morbidity and mortality due to stroke were determined and correlated to the potential risk factors every year separately and as a cumulative value for the whole 10-year period.

**Results:** At the beginning of the study a previous stroke history was found in 62 persons - 34 females and 28 males. The initial prevalence of stroke was 4.6%. In the 10-year period, 135 new episodes of stroke were observed, that is, 7.5%. The cumulative incidence of stroke was equal to 12.1%, that is, 10.8 cases per 1,000 patient - years. The mortality index due to stroke was 11.0%. The significance of the selected clinical risk factors was subjected to multivariate statistical analysis. The risk factors with statistically valid, pathogenic significance were: 1.) age (RR- 1.05, 95% CI 1.03 - 1.07;  $p<0.001$ ), 2.) fasting glycemia (RR- 1.99, 95% CI 1.17 - 3.39;  $p<0.05$ ), 3.) daily albuminuria (RR- 1.98, 95, 95% CI 1.02 - 4.06;  $p<0.05$ ), 4.) atrial fibrillation (RR- 2.91, 95% CI 1.39 - 6.09;  $p<0.01$ ) and 5.) smoking (RR- 1.97, 95% CI 1.17 - 3.00;  $p<0.01$ ).

**Conclusion:** Among 1,334 cases of the studied cohort of type 2 diabetes mellitus observed during the 10-year period in the same outpatient clinic, the cumulative stroke incidence was 12.1%, that is, 10.8 of cases per 1,000 person-years. The cumulative mortality reached the level of 11.0%. The main objectively established clinical risk factors for the stroke were age, of patients fasting glycemia, daily albuminuria, atrial fibrillation and smoking. This information should be taken under consideration in establishing an individual plan of stroke prevention.

## 18

**Effects of type 2 diabetes on 12-year cognitive change: results from the MAAS prospective cohort study**P.J.J. Spauwen<sup>1</sup>, S. Köhler<sup>1</sup>, F.R.J. Verhey<sup>1</sup>, C.D.A. Stehouwer<sup>2</sup>, M.P.J. van Boxtel<sup>1</sup><sup>1</sup>Psychiatry and Neuropsychology, School for Mental Health and Neuroscience (MHeNS), <sup>2</sup>Internal Medicine, Cardiovascular Research Institute (CARIM), Maastricht, Netherlands.

**Background and aims:** Type 2 diabetes is associated with an increased risk of cognitive impairment and dementia. Despite this increased risk, results from studies into the cognitive trajectories of patients with type 2 diabetes have been inconclusive. The aim of the present study was to investigate the effect of baseline and incident type 2 diabetes on change in cognitive performance over 12 years.

**Materials and methods:** A sample of 1,290 individuals aged 40 years and older at baseline, participating in the Maastricht Aging Study (MAAS), were cognitively tested at baseline, after six years, and after 12 years. Of these, 68 participants had type 2 diabetes at baseline, and 54 and 57 had incident diabetes at 6-year and 12-year follow-up, respectively. Changes in performance on tests of information processing speed, executive function, and verbal memory from baseline to 6-year and to 12-year follow-up were compared between groups. Effects of diabetes on cognitive decline were adjusted for demographic variables, history of smoking, alcohol intake, and comorbid conditions including hypertension, cardiovascular disease, body mass index, and depression.

**Results:** Linear mixed model analysis was used to test effects of baseline and incident diabetes on cognitive decline. Participants with baseline diabetes showed a larger decline in information processing speed (estimate, -7.64, 95% confidence interval, -10.47 to -4.81), in executive function (21.82, 13.57 to 30.06), and in delayed word recall (-1.35, -2.50 to -0.20) over 12-year follow-up compared with controls, after adjustment for demographic variables, history of smoking, alcohol intake and comorbid conditions. No significant difference in decline was observed for immediate word recall (-1.88, -5.28 to 1.52). Interestingly, participants with incident diabetes did not show a larger decline in any cognitive domain compared with controls.

**Conclusion:** This study clearly indicates that patients with baseline type 2 diabetes show accelerated cognitive decline compared with individuals without diabetes, while patients with incident diabetes do not yet show this decline. This might provide a window of opportunity for prevention and early treatment of diabetes related cognitive deficits. For this, it is important to assess cognitive status at an early stage of the disease and to repeat cognitive assessments on a regular basis.

**Figure 2 | Adjusted effect of type 2 diabetes on change in information processing speed from baseline to 6-year and to 12-year follow-up**

## OP 04 Insulin action in the liver

## 19

**In vivo mechanisms of saturated and unsaturated fat-induced hepatic insulin resistance**T. Galbo<sup>1</sup>, T. Alves<sup>1</sup>, M. Kahn<sup>1</sup>, D. Zhang<sup>1,2</sup>, V.T. Samuel<sup>1,2</sup>, G.I. Shulman<sup>1,2</sup><sup>1</sup>Internal Medicine and Endocrinology, Yale University School of Medicine, USA, <sup>2</sup>Howard Hughes Medical Institute, New Haven, USA.

**Background and aims:** Ectopic lipid accumulation in the liver is strongly associated with hepatic insulin resistance, however, the cellular mechanism by which intracellular lipid-induces hepatic insulin resistance is controversial. It has been hypothesized that saturated (sat) and unsaturated (unsat) fatty acids (FAs) cause hepatic insulin resistance through divergent mechanisms, where sat FAs cause insulin resistance through activation of a TLR pathway leading to activation of Protein Phosphatase 2A (PP2A) and inhibition of insulin signalling at the level of AKT2 phosphorylation, whereas unsat FAs lead to accumulation of diacylglycerols (DAGs) leading to activation of PKCε leading to reduced insulin signalling at the level of the insulin receptor kinase. In this study we examined this hypothesis by directly comparing the effects of sat- and unsat-fat diet on hepatic insulin signalling in awake rats.

**Materials and methods:** Male S-D rats were fed either a chow diet or a high-fat diet (60% calories from fat) based on lard (sat) or safflower (unsat) for three days to specifically induce hepatic insulin resistance. Basal parameters were determined in one set of rats (n=10 per group) while separate groups of rats were infused with insulin to assess the effects of the different diets on insulin signalling (n=6 per group). Statistical significance was determined by ANOVA followed by post hoc t-test.

**Results:** Rats fed either a sat or unsat high-fat diet manifested increased plasma FAs (~50 and 100%, P<0.05 and P<0.001 respectively), liver triglycerides (~2- and 3-fold, P<0.05 and P<0.001) and DAGs (both ~3-fold, P<0.05 and P<0.01) compared to the chow fed rats. Furthermore, both sat and unsat high-fat diets were associated with a ~5-fold increase in activation of PKCε (P<0.05) and an ensuing reduction in insulin-stimulation of IRS1 and IRS2 tyrosine phosphorylation (~50-70%, P<0.05). Both sat and unsat diets led to a relatively small ~20% (P<0.05 and P<0.01) increase in activity of the Akt-inactivating PP2A. Furthermore both sat and unsat diets resulted in a ~50% reduction in insulin-stimulated phosphorylation of the nuclear Akt2 substrate and transcriptional inducer of gluconeogenic gene expression, FoxO1 (both P<0.05). Consistent with this, we found an impairment of insulin-stimulation of Akt2 translocation to the plasma membrane (~30%, P<0.05) and nucleus (~50%, P<0.05), and a ~40% (P<0.01) decrease in insulin-stimulation of nuclear levels of phosphorylated, active Akt2 in animals fed either sat or unsat diets.

**Conclusion:** Taken together our data suggest that saturated and unsaturated fatty acids promote hepatic insulin resistance through a similar mechanism involving DAG activation of PKCε resulting in decreased insulin stimulation of IRS-1 and IRS-2 tyrosine phosphorylation and possibly through activation of PP2A.

## 20

**Induction of a hepatic lipid droplet protein induces a hepatic steatosis without insulin resistance**K. Minehira<sup>1</sup>, T. Bouduban<sup>1</sup>, P. Gual<sup>2</sup>, A. Tran<sup>2</sup>, S. Bonnafant<sup>2</sup>, F. Mange<sup>1</sup>, G. Willemin<sup>1</sup><sup>1</sup>Department of Physiology, University of Lausanne, Switzerland, <sup>2</sup>Equipe 8 complications hépatiques de l'obésité, INSERM, U895, Nice, France.

**Background and aims:** It has been believed that an abnormal lipid accumulation in tissues, such as a hepatic steatosis, induces insulin resistance via lipid intermediates. In hepatocyte, neutral lipids are stored inside of lipid droplets which consist of a phospholipid monolayer and lipid droplet proteins such as perilipins on their surface. Any degradation of the neutral lipids from lipid droplets could contribute to the accumulation of lipid intermediates. However whether the lipid droplet proteins are implicated in the development of hepatic insulin resistance has not been understood. We hypothesized that these lipid droplet proteins increase a capacity of hepatocytes to store lipids and protect against the insulin resistance.

**Materials and methods:** We studied the effect of perilipin 5 (Plin5) in mouse hepatocytes (AML-12 cells) by overexpressing with an adenoviral vector, or

by downregulating with a siRNA technique. Triglyceride content and the insulin sensitivity were measured by a chemical analysis and by a western blotting respectively. In addition, we studied the effect of Plin5 overexpression in mice and checked a degree of hepatic steatosis and a presence of insulin resistance. In order to understand their roles in human, we studied the expression of Plin5 in the liver biopsies from patients with diverse hepatic steatosis. We also compared the expression in the liver from patients with or without diabetes.

**Results:** Overexpression of Plin5 significantly induced triglycerides accumulation compared to the control cells. On the contrary, the downregulation resulted in the formation of abnormal fractionated lipid droplets in AML-12 cells. The hepatic steatosis induced by the overexpression of Plin5 was dissociated from insulin resistance, however the downregulation of Plin5 strongly induced insulin resistance in AML-12 cells. As found in in-vitro studies, mice overexpressing Plin5 in the liver developed a severe hepatic steatosis. Their insulin sensitivity was intact judged by a pyruvate tolerance test and by a phosphorylation of Akt upon an insulin injection. In human liver biopsies, the expression of Plin5 was higher in patients with severe hepatic steatosis. Interestingly, once the patients developed diabetes, this induction of Plin5 was not observed any more.

**Conclusion:** Our in-vitro and in-vivo studies clearly demonstrated that the induction of Plin5 augmented the capacity of hepatocytes to store triglycerides. Despite this induction of hepatic steatosis, these cells/livers remained insulin sensitive, supporting our hypothesis of the protective role of Plin5 against insulin resistance. In line with the concept, when Plin5 was downregulated, cells became insulin resistant. Together with the data from the human diabetic liver which presented low Plin5 expression, we believe that the Plin5 might protect the fatty liver against the development of insulin resistance by increasing the capacity to store neutral lipids in hepatocytes.

**Proteomic analysis of livers from fat-fed PKCε and PKCδ KO mice: insights into the modulation hepatic lipid metabolism as well as insulin action by PKC isoforms**

C. Schmitz-Peiffer<sup>1</sup>, K. Raddatz<sup>1,2</sup>, B.-Q.M. Liao<sup>1</sup>, B. Diakanastasis<sup>1</sup>;

<sup>1</sup>Diabetes and Obesity Program, Garvan Institute of Medical Research, Sydney, Australia, <sup>2</sup>ZIK Functional Genomics, University of Greifswald, Germany.

**Background and aims:** Specific lipid intermediates, including diacylglycerols (DAG), play roles in the inhibition of insulin action. Protein kinase C (PKC) isoforms are activated by DAG, and we have shown that deletion of either of PKCδ or PKCε improves glucose tolerance in fat-fed mice. We also demonstrated that these PKC isoforms play unexpected roles in the modulation of hepatic lipid metabolism itself. PKCδ-deficient mice show reduced triglyceride (TG) accumulation in the liver whereas PKCε-deficient mice exhibit increased TG storage. These models were therefore employed in proteomic and physiological experiments in order to gain insights into the regulation of lipid metabolism and insulin action in the liver.

**Materials and methods:** We performed quantitative proteomic analyses of livers from chow- and fat-fed wildtype (WT) and PKCδ and PKCε KO mice, using an in vivo adaptation of stable isotope labelling with amino acids in cell culture (SILAC) methodology. We measured ketone bodies and glucose in blood from fed and fasted WT and PKCε KO mice. We employed isolated primary hepatocytes from these animals to examine lipid metabolism using tracers.

**Results:** For each PKC, the expression ratios of approximately 3000 proteins were determined in the 4 groups of animals, in each of two separate experiments. Of these, 23 proteins were upregulated by >1.5-fold in livers from fat-fed PKCδ KO mice, compared to fat-fed WT mice in each experiment, and 6 proteins were downregulated >1.5-fold. Similarly, 18 proteins were upregulated in livers from fat-fed PKCε KO mice, and 17 proteins were downregulated. These included enzymes of lipid, cholesterol and amino acid metabolism, proteins linked to redox stress and also cytoskeletal and nuclear proteins. Certain proteins were affected by both PKC isoforms, either in a similar or a reciprocal manner, consistent with a role either in the improvement in insulin sensitivity or in the isoform-specific effects on TG storage respectively. In particular, enhanced expression of specific oxidoreductases correlated with improved insulin action. In addition, pathway analysis of the sets of altered proteins implicated PKCε in the regulation of cholesterol and ketone body synthesis. In agreement, cholesterol synthesis was found to be elevated by over 2-fold in PKCε KO hepatocytes. Total cholesterol, however,

was not correspondingly increased, suggesting additional effects on its downstream metabolism. Furthermore, in fasted PKCε KO mice, the rise of blood ketone levels was reduced by 40%, whereas blood glucose levels remained 30% higher than those of WT mice.

**Conclusion:** Proteomic analysis of livers from PKC KO mice has generated new avenues for investigation into mechanisms by which these kinases regulate hepatic lipid metabolism, and also how their deletion may lead to an improvement in insulin sensitivity in fat-fed mice. We have also uncovered a novel phenotype of PKCε KO mice, which exhibit improved glucose homeostasis and reduced ketogenesis upon fasting. Together with the previously reported improvement in insulin action upon fat-feeding, this further promotes PKCε as a key therapeutic target for the treatment of glucose intolerance.

**Transient increase in mitochondrial oxidative capacity during the development of insulin resistance in a mouse model of non-alcoholic fatty liver**

T. Jelenik<sup>1</sup>, G. Séquaris<sup>1</sup>, J. Szendrödi<sup>1,2</sup>, J. Kotzka<sup>3</sup>, E. Phielix<sup>1</sup>, B. Knebel<sup>3</sup>, P. Nowotny<sup>1</sup>, H.-J. Partke<sup>1</sup>, D. Müller-Wieland<sup>4</sup>, M. Roden<sup>1,2</sup>;

<sup>1</sup>Institute for Clinical Diabetology, German Diabetes Center, Heinrich Heine University, Leibniz Center for Diabetes Research, Düsseldorf, <sup>2</sup>Clinic for Metabolic Diseases, University Clinic Düsseldorf, Heinrich Heine University, <sup>3</sup>Institute for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Heinrich Heine University, Leibniz Center for Diabetes Research, Düsseldorf, <sup>4</sup>Asklepios Clinic St. Georg, Hamburg, Germany.

**Background and aims:** Non-alcoholic fatty liver (NAFL) and ectopic lipid storage in skeletal muscle have been associated with insulin resistance and abnormal mitochondrial function in obesity and type 2 diabetes. The underlying causal relationships are yet unclear. The aim of this study was to determine the role of mitochondrial function during the development of lipid-induced NAFL and insulin resistance.

**Materials and methods:** We examined liver and muscle metabolism in 18- and 36-weeks-old female mice with secondary NAFL due to adipose tissue-specific overexpression of the sterol regulatory-element binding protein-1c (aP2-SREBP-1c: AP2; n=6-7) and in age- and sex-matched wild-type controls on C57BL/6 background (CON; n=6-7). Insulin sensitivity was determined in 36-weeks-old mice by hyperinsulinemic-euglycemic clamps in combination with the isotope glucose technique. Mitochondrial oxidative capacity was measured in permeabilized tissues using high-resolution respirometry (Oroboros Instruments) and mitochondrial content was assessed from the ratio of mitochondrial DNA to nuclear DNA, using quantitative PCR.

**Results:** Mean liver weight was 37% and 86% higher (p<0.001) in 18-weeks-old and in 36-weeks-old AP2 mice when compared to CON. Mitochondrial oxidative capacity was improved in 18-weeks-old AP2 mice as assessed by 75% greater pyruvate-dependent mitochondrial respiration in liver (p<0.05) and 93% greater fatty acid-dependent mitochondrial respiration in muscle (p<0.05). On the other hand, 36-weeks-old AP2 mice displayed 25% lower (p<0.05) pyruvate-dependent muscle mitochondrial respiration. Mitochondrial content in muscle and liver remained unchanged. Basal endogenous glucose production (EGP) was doubled in AP2 mice at the age of 36-weeks (31±4, CON: 17±2 mg/kg/min; p<0.05). These results were in accordance with higher 6-h fasting serum glucose (216±16, CON: 108±14 mg/dl; p<0.05). Furthermore, 36-weeks-old AP2 mice had 43% lower insulin-mediated glucose disposal in peripheral tissues (33±4, CON: 57±9 mg/kg/min; p<0.05). Insulin suppression of EGP as well as serum non-esterified fatty acids was not affected by the AP2 genotype.

**Conclusion:** Initially, hepatic steatosis transiently increases oxidative capacity to compensate for elevated energy supply. However, later stages of NAFL are associated with decreased oxidative capacity and impaired insulin sensitivity in muscle of AP2 mice.

### Comparison between intraperitoneal and subcutaneous insulin infusion: link between routes of administration and hepatic oxidative stress

S. Ros<sup>1</sup>, S. Sigrist<sup>1</sup>, E. Seyfritz<sup>1</sup>, W. Bietiger<sup>1</sup>, C. Péronet<sup>1</sup>, M. Pinget<sup>2,3</sup>, N. Jeandier<sup>2</sup>;

<sup>1</sup>Centre Européen d'Etude du Diabète, <sup>2</sup>Service d'Endocrinologie, Diabète, Maladies Métaboliques, <sup>3</sup>Université de Strasbourg, Strasbourg, France.

**Background and aims:** Subcutaneous insulin infusion (CSII) is nowadays the gold standard for type 1 diabetic patient therapy. Continuous Intraperitoneal Insulin Infusion (CPII), in contrast to peripheral SC route, allows physiological portal insulin administration, first hepatic bypass and partial normalization of hepatic metabolism. However, its impact on oxidative stress (OS), leading to chronic complications is not known. The aim of this study was to compare metabolic and oxidative parameters in these two modes of insulin administration, at the same dose, in diabetic rats.

**Materials and methods:** Diabetic Wistar rats (streptozotocin, 100mg/kg) were randomized into 3 groups: diabetic rats with no insulin, with Insuplant® (7UI/200g/j) in Alzet osmotic mini-pump in CSII or CPII during 1 (W<sub>1</sub>) or 4 weeks (W<sub>4</sub>), compared to age match-controls. Blood glucose, fructosamine, IGF-1, total antioxidant capacity (TAOC) and lipid peroxides were determined in plasma. Liver and mesenteric artery OS were assessed by the probe dihydroethidine and liver glycogen and apoptosis were quantified. Redox-sensitive pathways implicated in glucose metabolism and glucocorticoid receptor (GR) were determined by Western blotting.

**Results:** In addition to better fructosamine (W<sub>4</sub>: p=.006) and limitation of weight loss with CPII (after 20 days: p=.016, W<sub>4</sub>: p=.006) in equal doses, CPII specifically protected the liver from diabetes induced-OS, in comparison to vessels OS, increased the expression of catalase and superoxide dismutase (antioxidant enzymes) in the liver. Both insulin treatments normalized p67phox, a subunit of NADPH oxidase (antioxidant enzymes) and protected against the activation of p38 (redox-sensitive kinase) in the liver, ensuring the maintenance of an intermediary TAOC between non-diabetic and diabetic-rats and protecting against lipid peroxidation. Both insulin treatments protected against the beginning (W<sub>4</sub>) of liver apoptosis observed in diabetic rats. CPII decreased density of diabetes induced-liver macrophages, but have no effect on systemic inflammation associated with diabetes (α2-macroglobulin). From W<sub>1</sub>, CPII allowed the restoration of liver glycogen storage and preserved the phospho-akt/glucose synthase kinase 3 pathway implicated in glycogen synthesis. Better release of IGF-1 was observed from W<sub>1</sub> during CPII and preferably but not significantly at W<sub>4</sub>. Moreover, all these beneficial effects of CPII on liver were associated with an upregulation of GR expression from W<sub>1</sub>.

**Conclusion:** CPII induced better glycaemic control with the same insulin doses than CSII. Hepatic oxidative stress and its consequences associated with diabetes are prevented by CPII, including the fine regulation of the anti-/pro-oxidant enzymes balance. CPII provided a better release of IGF-1 and a restocking of hepatic glucose by preserving in part the liver metabolic pathway. All these results could play a role in improving glycaemic fluctuations and demonstrated the importance of focusing on the first hepatic bypass of insulin, all for the limitation/prevention of diabetic complications.

### Novel PEGylated basal insulin LY2605541 has a preferential hepatic effect on glucose metabolism

M.C. Moore<sup>1</sup>, M.S. Smith<sup>1</sup>, K.F. Mace<sup>2</sup>, V.P. Sinha<sup>2</sup>, M.D. Michael<sup>2</sup>, S.J. Jacober<sup>2</sup>, J.M. Beals<sup>2</sup>, A.D. Cherrington<sup>1</sup>;

<sup>1</sup>Molecular Physiology & Biophysics, Vanderbilt University, Nashville, <sup>2</sup>Lilly Research Laboratories, Eli Lilly & Company, Indianapolis, USA.

**Background and aims:** LY2605541 (LY) is insulin lispro with a 20 kDa polyethylene glycol (PEG) moiety covalently attached to lysine B28. LY is designed to have a large hydrodynamic size that slows absorption and reduces clearance, resulting in a longer duration of action. To assess the impact of PEGylation on the pharmacodynamics of insulin lispro, LY was compared to regular insulin in vivo.

**Materials and methods:** Euglycemic clamps were carried out in conscious dogs. The studies were initiated with a primed, continuous infusion of [3-<sup>3</sup>H]glucose via peripheral vein (Pe). After 90 minutes of tracer equilibration, there was a 30-minute basal period and a 5-h clamp period. Infusions during the clamp period were: Pe regular insulin (0.3 mU/kg/minute; insulin control

[CONTROL], n=6) or LY (0.5 nmol/kg bolus then 0.5 nmol/kg/h, n=6); Pe somatostatin; intraportal glucagon (basal replacement); and Pe glucose.

**Results:** Both groups exhibited basal net hepatic glucose output at 1.9 mg/kg/minute. In CONTROL, this gradually fell to 0, but in LY the liver switched to net uptake within 30 min, reaching a rate of 1.1±0.2 mg/kg/minute during the last hour (CONTROL vs. LY, P<0.05). At the end of the clamp, glucose rate of appearance (R<sub>a</sub>) was suppressed by 1.6±0.3 and 2.3±0.2 mg/kg/minute in CONTROL and LY, respectively (P<0.05), and unidirectional hepatic glucose uptake was 33% higher in LY than in CONTROL (P=0.06). Non-hepatic glucose uptake in LY increased less than in CONTROL (last h: 0.7±0.3 vs. 2.0±0.8 mg/kg/minute above basal). The glucose infusion rates (3.9±0.9 and 3.9±0.6 mg/kg/minute) and glucose rate of disappearance (R<sub>d</sub>; 5.2±0.8 and 4.6±0.7 mg/kg/minute) were not significantly different during the final hour in CONTROL and LY, respectively. Arterial glycerol and nonesterified fatty acid levels fell in CONTROL but initially increased in LY, thereafter falling and converging with those in CONTROL near the end of the study.

**Conclusion:** These data demonstrate that LY2605541 has a preferential hepatic effect similar to endogenously produced insulin and different from exogenously administered human insulin.

## OP 05 New modulators of energy expenditure

25

### Fibroblast growth factor 21 (FGF21) increases energy expenditure in a leptin-dependent manner

T. Coskun, A.C. Adams, S.L. DuBois, L.S. O'Farrell, C. Cheng, A. Kharitonkov;  
Endocrine, Eli Lilly and Company, Indianapolis, USA.

**Background and aims:** FGF21 regulates whole body metabolism through distinct actions on the liver, white and brown adipose tissues. Previously, we have demonstrated that FGF21 corrects obesity in part via increasing energy expenditure. However, the mechanism of action mediating this increase is poorly understood. In earlier studies, we observed that chronic FGF21 treatment up-regulated leptin receptor gene expression in liver and white adipose tissue. Interestingly, while receptor expression was increased FGF21 administration caused a significant reduction in plasma leptin levels suggesting FGF21 may act in part via leptin sensitization. In series of *in vivo* studies, we aimed to investigate the interaction between FGF21 and leptin with regards to the regulation of body weight and energy expenditure.

**Materials and methods:** Lean, diet-induced obese or ob/ob mice were chronically treated with FGF21, leptin, or a combination of both leptin and FGF21 and body weight, food intake, and energy expenditure were measured.

**Results:** Our results demonstrated that subcutaneous leptin or FGF21 infusion decreased body weight in a dose responsive manner in lean C57/BL6 mice. In DIO mice, leptin infusion alone (up to 100 µg/mouse/day) did not cause any BW reduction, however, FGF21 treatment caused even greater body weight reduction in DIO mice than we observed in lean mice. Importantly, treatment with a combination of leptin in addition to FGF21 restored leptin sensitivity in DIO mice with the combination demonstrating increased efficacy when compared to either agent alone or the summation of the two suggesting synergistic effects. In ob/ob mice FGF21 led to a modest reduction in body weight, however, this reduction was significantly blunted when compared to the magnitude of the effect observed in DIO mice. Furthermore, in the ob/ob mice the energy expenditure effect of FGF21 was largely absent suggesting leptin is required for FGF21 to modulate metabolic rate. Supporting this hypothesis we demonstrate that replacement of leptin in ob/ob mice restores the FGF21 effect on energy expenditure.

**Conclusion:** Therefore, we conclude that FGF21 is able to rapidly and robustly increase leptin sensitivity in states of diet induced obesity and may provide additional avenues for pharmacological intervention with this protein.

26

### Metabolic effects of mitochondrial uncoupling in murine skeletal muscle: essential role of AMP-activated protein kinase in metabolic improvements of UCP1-transgenic mice?

M. Ost, A. Voigt, S. Keipert, J. Dokas, S. Klaus;  
Department of Pharmacology/ Group of Energy Metabolism, German Institute of Human Nutrition, Nuthetal, Germany.

**Background and aim:** Altering the efficiency of mitochondrial respiration may represent an attractive target for the treatment of obesity as well as related disorders. Transgenic (UCP1-TG) mice with ectopic expression of UCP1 in skeletal muscle (SM) show a phenotype of increased energy expenditure and improved glucose tolerance counteracting most of the detrimental effects of high fat diet. We could show an increased AMPK phosphorylation in SM of UCP1-TG mice, likely due to the energy depletion through uncoupling by UCP1. However, the full molecular mechanisms leading to the ameliorated metabolic phenotype of UCP1-TG mice are still not known. The aim of this study was to investigate the potential role of skeletal muscle AMPK activation in the healthy metabolic phenotype of UCP1-TG mice.

**Material and methods:** We generated double transgenic (DTG) mice, by crossing of UCP1-TG mice with DN-AMPK mice overexpressing a dominant negative  $\alpha 2$  subunit of AMPK in SM which results in decreased AMPK activity. For basal characterization we investigated body composition, energy metabolism, glucose homeostasis and physical activity under standard chow diet in young male & female wild-type (WT) and TG mice (DN-AMPK, UCP1-TG, DTG). At 12 weeks of age mice were killed for analysis of substrate metabolism in SM (AMPK activity, *ex vivo* glucose uptake).

**Results:** Skeletal muscle AMPK activity was assayed *in vitro* by incorporation of  $^{32}\text{P}$  into a synthetic SAMS peptide after immunoprecipitation of AMPK $\alpha$  subunits. As expected, AMPK $\alpha 2$  activity was increased by  $50 \pm 20\%$  ( $p < 0.01$ ) in SM of UCP1-TG mice, whereas in DN-AMPK and DTG mice AMPK $\alpha 2$  activity was impaired by  $90 \pm 9\%$  ( $p < 0.001$ ). AMPK $\alpha 1$  activity was not affected in any genotype. Biometric analysis showed decreased body weight, lean, and fat mass for both UCP1-TG and DTG compared to WT and DN-AMPK mice. DTG mice showed slightly reduced body weight and significant decreased body length ( $p < 0.001$ ) compared to UCP1-TG mice, but no differences in body composition. Energy intake and weight-specific total energy expenditure were increased, both in UCP1-TG and DTG mice. Moreover, weight-specific resting energy expenditure was increased in DTG mice only ( $p < 0.001$ ). In addition, voluntary physical activity during night was decreased in DTG mice ( $p < 0.05$ ). Basal glucose uptake in EDL muscle *ex vivo* was significantly increased in UCP1-TG ( $p < 0.01$ ), but not in DTG mice compared to WT. However, maximum insulin stimulated glucose uptake was similar in all genotypes. No gender differences were observed.

**Conclusion:** Collectively, the first basal characterization shows that the reduction of AMPK $\alpha 2$  activity in SM slightly affects biometrics, energy metabolism and physical activity of young DTG compared to UCP1-TG mice. *In vivo* metabolic challenges (dietary intervention, exercise endurance) and further *ex vivo/ in vitro* pathway analysis will follow to elucidate the role and significance of AMPK on energy and substrate metabolism in UCP1-TG mice in more detail.

27

### Conventional knockout of Tbc1d1 in mice results in impaired insulin-stimulated glucose uptake in skeletal muscle but has no impact on whole body glucose and insulin tolerance

A. Chadt<sup>1</sup>, J. Dokas<sup>2</sup>, T. Nolden<sup>3</sup>, H. Himmelbauer<sup>4</sup>, H.-G. Joost<sup>2</sup>, H. Al-Hasani<sup>1</sup>;

<sup>1</sup>Biochemistry, German Diabetes Center (DDZ), Duesseldorf, Germany, <sup>2</sup>Pharmacology, German Institute of Human Nutrition (DIfE), Potsdam-Rehbruecke, Germany, <sup>3</sup>Max Planck Institute for Molecular Genetics, Berlin, Germany, <sup>4</sup>Centre for Genomic Regulation (CRG) and UPF, Barcelona, Spain.

**Background and aims:** We recently demonstrated that the lean and diet-induced obesity-resistant SJL mouse strain carries a loss-of-function mutation in the signalling protein TBC1D1. Introgression of a 10 Mb fragment containing this non-functional allele into a C57BL/6J background (Recombinant congenic strain, RCS) resulted in mice with reduced body weight and body fat. Moreover, the respiratory quotient of these animals was decreased, indicating increased whole body lipid utilization due to the lack of TBC1D1. *Ex vivo* experiments in intact isolated skeletal muscles showed an increase in fatty acid oxidation (FAO) but on the other hand a reduced insulin-stimulated glucose uptake. However, except of the non-functional *Tbc1d1* gene, additional 53 genes from SJL were present in the genome of the RCS mice. Therefore, we generated a conventional *Tbc1d1*-knockout (KO) mouse using the genetrap technology in order to exclusively link the observed phenotype to the mutated *Tbc1d1* gene.

**Material and methods:** Body weight and body composition of mice on a standard diet were regularly monitored. At distinct time points, respiratory quotient as well as energy expenditure was measured and the mice underwent intraperitoneal glucose and insulin tolerance tests. In parallel, we measured blood glucose and plasma insulin values after a period of 16 h fasting and also postprandially. Finally, EDL (*Extensor digitorum longus*) and soleus muscle were dissected and *ex vivo*  $^3\text{H}$ -palmitate oxidation and  $^{14}\text{C}$ -2-DOG (deoxyglucose) uptake were measured.

**Results:** In agreement with our previous results, conventional *Tbc1d1*-knockout mice displayed a reduced body weight. Moreover, these mice also showed a decreased respiratory quotient and an elevated resting metabolic rate (RMR), indicating moderately increased energy expenditure. Also, GLUT4 protein content was decreased by approximately 50% in glycolytic skeletal muscle of *Tbc1d1*-deficient mice whereas expression of the related signaling protein AS160 (TBC1D4) and the glucose transporter GLUT1 were not changed. *Ex vivo* analysis of intact isolated skeletal muscle, revealed that *Tbc1d1* knockout results in enhanced FAO with concomitant decrease of insulin- and AICAR-stimulated glucose transport. Surprisingly, however, there were no gross alterations of whole-body glucose and insulin tolerance due to the lack of TBC1D1 in these mice.

**Conclusion:** Our present results suggest that the SJL-specific mutation in the *Tbc1d1* gene is at least in part responsible for the lean phenotype of SJL mice.

Furthermore, our data demonstrate that TBC1D1 is a critical component for glucose and fatty acid metabolism in skeletal muscle. Whole body glucose and insulin tolerance was not altered indicating compensation of the knockout by the related AS160 protein. Future analysis will clarify how exactly TBC1D1 interferes with GLUT4 protein content in the cell and how a deficiency of this RabGAP protein increases FAO.

### Morbid obesity is associated with decreased $\mu$ -opioid receptor binding in the brain reward circuit

H.K. Karlsson<sup>1</sup>, L. Tuominen<sup>1</sup>, J.J. Tuulari<sup>1</sup>, J. Hirvonen<sup>1</sup>, R. Parkkola<sup>2</sup>, P. Nuutila<sup>1</sup>, L. Nummenmaa<sup>1</sup>

<sup>1</sup>Turku PET Centre, <sup>2</sup>Department of Radiology, University of Turku, Finland.

**Background and aims:** Obesity has reached epidemic proportions worldwide, yet little is known about the brain mechanisms that predispose to overeating. Functional imaging studies suggest that overeating might be caused by an imbalance between the reward circuit (including the ventral striatum) and inhibitory networks (including the prefrontal and orbitofrontal cortices). The endogenous opioid system, particularly acting via the  $\mu$ -opioid receptor, mediates reward, and animal studies have suggested that  $\mu$ -opioid receptors are involved in the pathophysiology of obesity. Whether  $\mu$ -opioid receptors are altered in human subjects with obesity is unknown.

**Materials and methods:** To examine whether morbid obesity is associated with changes in brain  $\mu$ -opioid receptor binding we recruited 17 morbidly obese women (mean body mass index [BMI] 41.9, mean age 43) and 9 normal-weight women (mean BMI 23.6, mean age 41). We measured brain  $\mu$ -opioid receptor binding using positron emission tomography (PET) with [<sup>11</sup>C]carfentanil, a selective radioligand for  $\mu$ -opioid receptors. Radioactivity was measured with the GE Healthcare Discovery 690 PET/CT scanner for 51 min, and receptor binding was expressed in terms of BPND, which is the ratio of specific to non-displaceable binding in brain. BPND was calculated for each voxel using the simplified reference tissue model (SRTM) with occipital cortex as the reference region, and parametric BPND maps were compared between the groups using ROI analysis and full-volume statistical parametric mapping with SPM8.

**Results:** Morbidly obese patients had on average 37% lower [<sup>11</sup>C]carfentanil BPND than did control subjects in several brain regions relevant for reward processing in brain, including ventral and dorsal caudate nucleus. Full-volume analysis revealed that BMI correlated negatively with BPND in multiple components of the reward circuit including thalamus, caudate nucleus, amygdala and anterior cingulate cortex, further suggesting a direct link between low  $\mu$ -opioid binding and obesity.

**Conclusion:** We found decreased  $\mu$ -opioid binding in morbidly obese patients in several brain regions implicated in reward processing. Low  $\mu$ -opioid tone may represent a neural substrate for decreased hedonic responses to eating in obesity, and could thus make these individual susceptible to overeating in order to gain the desired hedonic response. Identifying the brain mechanisms involved in overeating is critical for developing new psychological and pharmacological treatments to curb the obesity epidemic. In the next phase of the study, we will examine whether these changes are reversible after bariatric surgery for obesity. Whether decreased  $\mu$ -opioid tone is a cause or consequence of obesity remains to be determined.

Clinical Trial Registration Number: NCT00793143

### Altered energy metabolism in skeletal muscle cells derived from morbidly obese subjects

V. Aas<sup>1</sup>, S.S. Bakke<sup>2</sup>, N. Niklolic<sup>2</sup>, J. Hjeltnes<sup>3</sup>, H. Thoresen<sup>2</sup>, A.C. Rustan<sup>2</sup>, <sup>1</sup>Institute of Pharmacy and Biomedical Laboratory Science, Oslo and Akershus University College of Applied Sciences, Oslo, <sup>2</sup>School of Pharmacy, University of Oslo, <sup>3</sup>The Morbid Obesity Center, Vestfold Hospital Trust, Tønsberg, Norway.

**Background and aims:** Obesity is strongly associated with insulin resistance and type 2-diabetes (T2D), and about 80 % of patients with T2D are overweight. A study in 2010 at the Morbid Obesity Center in Tønsberg, Norway, revealed that less than 1 out of 3 morbidly obese subjects (BMI >40 kg/m<sup>2</sup>) have T2D, indicating that many morbidly obese subjects possess certain char-

acteristics that protect them against developing T2D. The aim of the present study was to evaluate whether features of skeletal muscle can explain the different susceptibility to develop T2D.

**Methods:** We examined fatty acid and glucose metabolism, as well as metabolic flexibility in human skeletal muscle cells using radiolabeled precursors. Muscle cell mitochondrial and lipid content were examined by fluorescence staining and protein expression by Western blotting. The cells were derived from lean healthy donors (BMI 23 ± 0.9 kg/m<sup>2</sup>), morbidly obese with normal glucose tolerance (BMI 44 ± 2.0 kg/m<sup>2</sup>) and morbidly obese subjects with established type 2 diabetes (BMI 43 ± 1.5 kg/m<sup>2</sup>).

**Results:** Myotubes from obese donors were clearly insulin resistant, assessed by reduced insulin-stimulated phosphorylation of Akt. A 2-fold increase in fatty acid oxidation was observed in cells established from morbidly obese subjects and a approximately 40 % lower metabolic flexibility (measured as the ability of glucose to suppress oleic acid oxidation) compared to cells from lean subjects. The mitochondrial reserve capacity, assessed by oleic acid and glucose oxidation in presence of the mitochondrial uncoupler FCCP, was significantly higher in myotubes from obese T2D subjects than lean. Triacylglycerol lipolysis was 30 % higher for obese T2D subjects than obese with normal glucose tolerance, and lipid accumulation (measured as cell associated lipids and number of lipid droplets) was about 30 % lower. The mitochondrial content was decreased in myotubes from morbidly obese T2D donors compared to morbidly obese with normal glucose tolerance. Glucose uptake and oxidation was not different between the 3 groups.

**Conclusion:** The myotubes from morbidly obese donors maintain altered fatty acid metabolism in culture, and seem to rely more on fatty acid oxidation and are less flexible than myotubes from lean donors. Our data further indicate that lipolysis and mitochondrial capacity may be important for development of T2D in morbidly obese subjects.

## 30

### Regulation of hypothalamic POMC expression by MECP2 and its contribution to leptin resistance

X. Wang, W. Han;

Laboratory of Metabolic Medicine, Singapore Bioimaging Consortium, Agency for Science, Technology and Research (A\*STAR), Singapore.

**Background and aims:** Leptin signals through JAK2/STAT3 pathway to regulate hypothalamic Pomc expression, which is a key regulator of energy and glucose homeostasis. High level of circulating leptin that fails to regulate energy homeostasis is termed as leptin resistance. Leptin resistance can happen at different steps along leptin signaling pathway, including transcriptional regulation of Pomc expression. Maternal or perinatal programming can cause epigenetic changes on Pomc promoter, including DNA methylation. Moreover, epigenetic regulation of Pomc promoter can affect its expression. MECP2 is a key methyl-CpG-binding protein that is recruited to methylated DNA to regulate gene expression. Our aim is to examine the regulation of hypothalamic Pomc expression by MECP2, and whether and how this contributes to leptin resistance.

**Materials and methods:** A mouse line with MECP2 specifically deleted in POMC neurons was generated and metabolic phenotypes were analyzed in the male mice. Hypothalamic Pomc expression and Pomc promoter methylation was investigated to understand the underlying mechanism.

**Results:** The knockout (KO) mice were normal at birth, but started to show significantly higher bodyweight at the age of 15 weeks, with significantly higher body fat and lower body lean percentage. Metabolic chamber analysis revealed that the KO mice had increased food intake, higher respiratory exchange ratio (RER), and higher energy expenditure. Furthermore, the KO mice showed elevated leptin levels, suggesting the mice have developed leptin resistance. Pomc mRNA was found to be significantly downregulated in the hypothalamus of the KO mice. Finally, DNA methylation on Pomc promoter in the hypothalamus was significantly higher in the KO mice.

**Conclusion:** Our results show that lack of MECP2 in POMC neurons is associated with increased DNA methylation on Pomc promoter and decreased Pomc expression in the hypothalamus, which may account for the observed leptin-resistant phenotypes, such as increased food intake and higher body weight. This study demonstrates that MECP2 is a positive regulator of Pomc expression in the hypothalamus, and DNA methylation on Pomc promoter affects Pomc expression in the hypothalamus and contributes to leptin resistance.

## OP 06 What's new in the treatment of diabetic nephropathy?

31

**CCR2 inhibition improves renal function in diabetic BTBR ob/ob Mice**  
T.J. Sullivan, Z. Miao, R. Berahovich, B.N. Zhao, L. Ertl, T. Baumgart, A. Krasinski, T. Dang, S. Miao, J.P. Powers, J.C. Jaen, T.J. Schall; Biology, ChemoCentryx, Inc., Mountain View, USA.

**Background and aims:** Diabetic nephropathy represents a major complication of uncontrolled diabetes. The chemokine receptor CCR2 has been implicated in the recruitment of blood monocytes into kidney in response to stressors such as hypertension and hyperglycemia. In addition, parenchymal renal cells are thought to upregulate CCR2 under those pathological conditions. We describe for the first time the renal benefits associated with CCR2 inhibition in diabetic BTBR *ob/ob* mice, which develop a constellation of abnormalities that closely resemble advanced human diabetic nephropathy and has been proposed as one of the best mouse models for evaluating the efficacy of diabetic nephropathy therapeutics.

**Materials and methods:** CCX872 is a potent and selective, orally bioavailable small molecule CCR2 antagonist, which has previously shown efficacy on hyperglycemia and impaired renal function in various preclinical models (e.g., BKS *db/db* mice). In the present study, CCX872 was dosed daily to male BTBR *ob/ob* mice (age 8 or 16 weeks) for up to 12 weeks. Doses of CCX872 were selected to provide high (>90%) inhibition of blood leukocyte CCR2 throughout the course of the day. Weekly assessments included body weights, fasting plasma glucose, serum clinical chemistry panel, and 24-hr urinary volume and output of albumin, creatinine and glucose.

**Results:** Treatment with CCX872 for 5 weeks significantly reduced urinary albumin excretion rate (UAER) (CCX872: 1322 µg/day vs. vehicle control: 3158 µg/day;  $p=0.008$ ) and albumin:creatinine ratio (ACR) (CCX872: 3559 µg/mg vs. vehicle control: 6740 µg/mg;  $p=0.02$ ). Statistically significant improvements in UAER (1572 µg/day vs. 2882 µg/day;  $p=0.002$ ) and urinary ACR (4418 µg/mg vs. 9118 µg/mg;  $p=0.005$ ) were seen as early as 2 weeks after initiation of CCX872 treatment. Serum markers of renal function were also improved after 5 weeks of CCX872 treatment: serum creatinine (0.32 mg/dL vs. 0.67 mg/dL;  $p=0.04$ ) and blood urea nitrogen (32 mg/dL vs. 100 mg/dL;  $p=0.05$ ). The benefits seen on renal function coincided with significantly reduced glomerular hyperfiltration, as determined by inulin-FITC clearance (679 µl/min vs. 1108 µl/min;  $p=0.03$ ). CCX872 was well tolerated and had no effects on body weights throughout the study.

**Conclusion:** Robust and rapid improvements of albuminuria, serum creatinine and blood urea nitrogen, and normalization of glomerular hyperfiltration were seen following administration of CCX872 to BTBR *ob/ob* mice suffering from pronounced hyperglycemia and impaired renal function. These results support the clinical evaluation of CCR2 antagonists for the treatment of diabetic nephropathy. Our group is currently conducting two Phase 2 diabetic nephropathy trials with CCX140-B, another orally active CCR2 antagonist that recently showed promising anti-diabetic effects in a Phase 2 trial in type 2 diabetic subjects.

32

**Association between glycation gap and macroproteinuria in type 2 diabetic patients**

I. Banu, E. Cosson, Y. Jaber, S. Chiheb, C. Cussac-Pillegand, M. Nguyen, N. Charnaux, P. Valensi; Dept of Endocrinology-Diabetology-Nutrition, Jean Verdier Hospital, AP-HP, CRNH-IdF, Paris-Nord University, Bondy, France.

**Background and aims:** Variation among diabetic patients in the intracellular glycation of proteins, independent of glycemia, could contribute to diabetic complications. The aim of the study was to evaluate a potential association between glycation gap (GG), i.e. the difference of glycation in the intra-erythrocyte compartment (HbA1c) and in the extracellular compartment (fructosamine), and complications in type 2 diabetic patients.

**Materials and methods:** We included 486 type 2 diabetic patients with high cardiovascular risk who underwent cardiovascular examinations including the detection of silent myocardial ischemia by stress scintigraphy and had concomitant measurement of HbA1c (turbimetric immuno-assay) and fructosamine (colorimetry). We assessed predicted HbA1c (HbA1c-F) from the correlation between fructosamine and HbA1c (HbA1c-F =  $(0.021 \times \text{fructosamine}) + 2.025$ ;  $r=0.72$ ;  $p<0.001$ ) and created 3 groups: "highGG" (the 5% patients with the highest HbA1c as compared to HbA1c-F), "lowGG" (5% in mirror) and "normalGG" (90% intermediate). A second series of 459 type 2 diabetic patients with a lower cardiovascular risk and no cardiac exploration was also tested.

**Results:** Body mass index (highGG / normalGG / lowGG  $28 \pm 7 / 30 \pm 6 / 32 \pm 8$  kg/m<sup>2</sup>,  $p=0.03$ ), HbA1c ( $7.0 \pm 1.5 / 8.7 \pm 2.0 / 12.3 \pm 1.5\%$ ,  $p<0.01$ ) and the prevalence of macroproteinuria ( $4.2 / 10.6 / 32.0\%$ ,  $p<0.01$ ) differed across GG groups, without significant difference for retinopathy, peripheral neuropathy nor silent myocardial ischemia. The association of GG groups with macroproteinuria persisted after adjustment on gender, age, body mass index and HbA1c (estimate -1.53,  $p=0.005$ ). Patients with vs without macroproteinuria had GG  $0.562 \pm 1.603$  vs  $-0.058 \pm 1.426$ ;  $p<0.01$ , and this difference persisted after adjustment. The results were concordant in the second series: macroproteinuria according to GG groups  $0 / 4.1 / 14.3\%$ ,  $p<0.01$  after adjustment; higher GG in macroproteinuric patients ( $0.481 \pm 1.105$  vs  $0.027 \pm 1.105$ ,  $p<0.05$  after adjustment).

**Conclusion:** In type 2 diabetic patients, GG is associated with macroproteinuria, independently of HbA1c and other confounding factors, suggesting a specific role of glycation susceptibility on kidney glomerule.

33

**Liver X receptor agonist ameliorates diabetic nephropathy by inhibiting high glucose-induced osteopontin expression in proximal tubular epithelial cells**

D. Ogawa;

Department of Diabetic Nephropathy, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan.

**Background and aims:** Osteopontin (OPN) is a proinflammatory cytokine implicated in the chemoattraction of monocytes and the development of diabetic nephropathy. Synthetic agonists for the Liver X Receptor (LXR), prevent the development of atherosclerosis by regulating cholesterol homeostasis and suppressing inflammatory gene expression, however, the role of LXR in diabetic nephropathy is poorly understood.

**Materials and methods:** We administered LXR agonist T0901317 (10 mg/kg/day) to STZ induced-diabetic mice for 8 weeks after inducing diabetes, and evaluated the effects for diabetic nephropathy. The mechanism of OPN expression was also analyzed in mProx24 cells, a mouse renal proximal tubular epithelial cell line, stimulated with high glucose medium and pretreated with T0901317.

**Results:** T0901317 decreased urinary albumin excretion without altering blood glucose levels. Macrophage infiltration, mesangial matrix accumulation, and interstitial fibrosis were substantially attenuated by T0901317. The gene expression of inflammatory mediators including OPN in the kidney cortex was also suppressed. *In vitro* studies demonstrated that LXR activation suppressed the expression of OPN in proximal tubular epithelial cells. This inhibition was mediated through an inhibition of AP-1 dependent transcriptional activation of the OPN promoter.

**Conclusion:** These findings uncover a previously unrecognized mechanism for the inhibition of renal OPN expression by activation of LXR and support the concept that LXR agonists may offer a novel therapeutic approach for the treatment of diabetic nephropathy.

## 34

**Metformin protects kidney cells from methylglyoxal-mediated damage**T.L. Buxton<sup>1</sup>, T. Loganathan<sup>1</sup>, J. Mabley<sup>2</sup>;<sup>1</sup>Brighton and Sussex Medical School, <sup>2</sup>School of Pharmacy & Biomolecular Sciences, University of Brighton, UK.

**Background and aims:** Methylglyoxal (MGO), a glycolysis derived reactive dicarbonyl compound has been implicated as a central mediator of diabetic complications in both Type I and Type II diabetes. Diabetes-mediated kidney complications are a leading cause of morbidity and mortality in this patient group and understanding the pathological mechanisms involved will allow for development of effective therapies. The aim of this study is twofold, firstly to examine the effects of MGO on kidney cell viability and secondly as metformin has a similar structure to aminoguanidine, a known scavenger of MGO, to investigate whether metformin could provide any direct protective effect against MGO-mediated deleterious effects

**Materials and methods:** The rat proximal tubular cell line, NRK-52E, was exposed to MGO (0.1–1 mM) for 24 h. Cell viability was determined using the MTT assay and cell death assessed by morphological analysis following propidium iodide/Hoechst staining. Oxidative stress was measured using the nitroblue tetrazolium assay. NRK-52E cells were also exposed to MGO (0.6–1 mM) ± aminoguanidine (0.1–0.5 mM) or metformin (0.1–0.5 mM) and again cell viability, apoptosis and necrosis levels, and oxidative stress was measured.

**Results:** NRK-52E cells exposed to MGO for 24 h showed a dose-dependent decrease in cell viability with 0.6 mM reducing it to 41 ± 1% ( $p < 0.05$  vs. untreated cells). There was also an increase in both necrosis, from 3 ± 1% to 41 ± 5%, and apoptosis, from 3 ± 1% to 14 ± 3%, following 0.6 mM MGO exposure ( $p < 0.05$  vs. untreated cells). MGO 0.6 mM also increased cellular oxidative stress following a 6 h exposure by 37 ± 7% ( $p < 0.05$  vs. untreated cells). Aminoguanidine proved effective in providing significant protection against MGO-mediated damage including at MGO concentrations of 0.8 and 1 mM. Metformin provided significant protection but was less effective than aminoguanidine providing protection only against MGO concentrations of 0.6 mM or lower. Metformin, 0.3 and 0.5 mM, increased cell viability to 54 ± 2% and 63 ± 3% respectively ( $p < 0.05$  vs. 0.6 mM MGO alone). Similar protective effects of metformin, 0.3 and 0.5 mM, against MGO-mediated increases in necrosis and apoptosis were also observed, necrosis being reduced to 17 ± 4% and 7 ± 3% ( $p < 0.05$  vs. 0.6 mM MGO) and 5 ± 2% ( $p < 0.05$  vs. 0.6 mM MGO alone) respectively. Both aminoguanidine and metformin reduced the MGO-mediated increase in cellular oxidative stress.

**Conclusion:** Physiological concentrations of MGO reduced rat kidney proximal tubular cell viability and increased levels of both necrosis and apoptosis. These effects may be mediated by the increased cellular oxidative stress observed following MGO exposure. Metformin was able to provide significant protection against the MGO-mediated loss of proximal tubule cell viability and increased apoptosis and necrosis. This data suggests that metformin, apart from its glucose-lowering effect, may also provide direct protection against methylglyoxal-mediated diabetic complications.

## 35

**DPP-4 inhibition with linagliptin delays the progression of diabetic nephropathy in db/db mice**Y. Sharkovska<sup>1</sup>, M. Alter<sup>2,3</sup>, C. Reichetzer<sup>2,4</sup>, O. Tsuprykov<sup>4</sup>, T. Klein<sup>5</sup>, B. Hoher<sup>4</sup>;<sup>1</sup>Institute of Vegetative Anatomy Charité Universitätsmedizin, Berlin,<sup>2</sup>Center for Cardiovascular Research / Institute of Pharmacology, Berlin,<sup>3</sup>Department of Nephrology, Charité Campus Benjamin Franklin, Berlin,<sup>4</sup>University of Potsdam, <sup>5</sup>Boehringer Ingelheim, Biberach, Germany.

**Background and aims:** Diabetic nephropathy is the main cause of end-stage renal disease worldwide. This study aimed to determine the effect of the dipeptidyl peptidase (DPP)-4 inhibitor linagliptin on diabetic nephropathy, independently of its glucose-lowering action.

**Materials and methods:** Male diabetic *db/db* mice at 10 weeks were divided into 3 groups and followed for a total of 12 weeks: vehicle ( $n = 10$ ), linagliptin 3 mg/kg/day ( $n = 8$ ) and enalapril 20 mg/kg/day ( $n = 10$ ). Heterozygous mice treated with vehicle were used as controls ( $n = 8$ ). Serum and urine samples were analysed for glucose, triglycerides, insulin, cystatin C and creatinine at baseline and monthly thereafter. Body weight, urinary albumin excretion and OGTT were monitored periodically. Renal histology (glomerulosclerosis, tubulointerstitial fibrosis) and expression of podocalyxin, glucagon-like pep-

tide-1 receptor (GLP-1R),  $\alpha$ -smooth muscle actin and type I collagen were evaluated at the end of the study.

**Results:** Compared with healthy control *db/+* mice, diabetic *db/db* mice showed substantially higher body weight and fasting serum levels of glucose, insulin and triglycerides. Neither linagliptin nor enalapril had significant effects on glucose levels and did not modify glucose disposal following OGTT in diabetic *db/db* mice. Urinary albumin excretion rates and tubulointerstitial fibrosis were significantly decreased in *db/db* mice treated with linagliptin compared with those treated with enalapril (both  $P < 0.05$ ). Glomerular mesangial matrix expansion in both treatment groups was reduced to almost the level observed in healthy control mice ( $P < 0.05$ ). The expression of podocalyxin in the glomeruli of *db/db* mice was lower than in healthy control mice ( $1.59 \pm 0.2$  vs.  $2.65 \pm 0.1$ ;  $P < 0.001$ ). Podocalyxin expression increased in the glomeruli of mice treated with linagliptin ( $2.31 \pm 0.15$ ) and enalapril ( $2.42 \pm 0.17$ ) compared with vehicle-treated diabetic *db/db* mice (both  $P < 0.05$ ). The expression pattern of  $\alpha$ -smooth muscle actin was also determined in kidneys as a marker of mesangial cell damage. Linagliptin treatment normalized the expression of  $\alpha$ -smooth muscle actin-positive myofibroblasts in the interstitium and glomeruli of diabetic *db/db* mice. Similar results were obtained for type I collagen deposition. Immunohistochemical staining of kidney sections revealed a decrease in GLP-1R expression in the cortical glomeruli of *db/db* mice ( $1.67 \pm 0.07$ ) compared with healthy control mice ( $2.15 \pm 0.1$ ;  $P < 0.01$ ). Linagliptin treatment significantly increased the expression of GLP-1R in the glomeruli of *db/db* mice ( $1.90 \pm 0.04$ ;  $P < 0.05$ ) compared with vehicle-treated diabetic *db/db* mice.

**Conclusion:** This study suggests that treatment with the DPP-4 inhibitor linagliptin protects against the progression of diabetic nephropathy independently of its effect on glucose lowering. The renoprotective action of linagliptin may be due to the inhibition of podocyte damage and myofibroblast transformation.

## 36

**Effects of the DPP-4 inhibitor linagliptin on albuminuria in patients with type 2 diabetes and diabetic nephropathy**P.-H. Groop<sup>1</sup>, M. Cooper<sup>2</sup>, V. Perkovic<sup>3</sup>, A. Emser<sup>4</sup>, T. Seck<sup>4</sup>, M. von Eynatten<sup>4</sup>, H.-J. Woerle<sup>4</sup>;<sup>1</sup>Department of Medicine, Division of Nephrology, Helsinki UniversityCentral Hospital, Finland, <sup>2</sup>The Baker IDI Heart and Diabetes Institute,Melbourne, Australia, <sup>3</sup>The George Institute for Global Health, Sydney,Australia, <sup>4</sup>Boehringer Ingelheim, Ingelheim, Germany.

**Background and aims:** Diabetes mellitus has become the most common single cause of end-stage renal disease and a high proportion of individuals with type 2 diabetes (T2D) are found to have microalbuminuria and overt nephropathy shortly after the diagnosis of their diabetes. Linagliptin, a DPP-4 inhibitor, has recently demonstrated glycaemic efficacy and safety in T2D patients at advanced stages of kidney disease. Here we report the clinical effect of linagliptin on albuminuria in T2D patients with early diabetic nephropathy.

**Materials and methods:** Seven randomised, double-blind, placebo-controlled trials (duration 24–52 weeks) of linagliptin as monotherapy or add-on to various glucose-lowering background therapies had data available for urinary albumin-to-creatinine ratio (UACR) and were eligible for this analysis ( $n = 4113$ ). Data after 24 weeks of treatment were generated to allow pooling and two sets were defined: 1) Diabetic nephropathy in earlier stages of T2D (with and without oral glucose-lowering background therapies): participants from four 24-week pivotal Phase 3 trials if they had persistent albuminuria, defined as  $30 \leq \text{UACR} \leq 3000$  mg/g and stable treatment with an angiotensin-converting enzyme inhibitor (ACEi) or angiotensin II receptor blocker (ARB) at baseline; 2) Diabetic nephropathy in elderly patients (various glucose-lowering background therapies including insulin): patients from all seven trials, fulfilling UACR criteria and aged  $\geq 65$  years. The endpoint in both sets was the percentage change in geometric mean UACR after 24 weeks.

**Results:** For set #1, 492 out of 2472 patients met UACR criteria of whom 46% received stable ACEi/ARB therapy (linagliptin,  $n = 168$ ; placebo,  $n = 59$ ). For set #2, 1331 patients were aged  $\geq 65$  years of whom 377 (28%) met UACR criteria (linagliptin,  $n = 232$ ; placebo,  $n = 145$ ). Mean baseline HbA1c and median UACR were 8.3% and 76 mg/g overall for set #1, and 8.1% (overall), 77 mg/g (linagliptin) and 86 mg/g (placebo) for set #2. In set #1, placebo-corrected changes in HbA1c and fasting plasma glucose were -0.71% and -1.4 mmol/L (-26 mg/dL), respectively (both  $P < 0.0001$ ). Linagliptin significantly lowered adjusted UACR by 33% (95% CI: 22%, 42%;  $P < 0.05$ ) with a between-group

difference versus placebo of -29% (95% CI: -3%, -48%;  $P<0.05$ ). In set #2, linagliptin also significantly lowered adjusted UACR by 30% (95% CI: 13%, 43%;  $P<0.05$ ) with a trend towards a reduction versus placebo of -25% (95% CI: -47%, +6%). In all seven studies, blood pressure and renal function were not affected to a clinically meaningful extent by either treatment.

**Conclusion:** In studies up to 52 weeks, linagliptin lowered albuminuria beyond what may be expected by its glucose-lowering effects. Potential long-term renal benefit of linagliptin needs to be explored.

## OP 07 What's new in insulin therapy?

### 37

#### Effect of peripheral delivery of a liver preferential insulin analogue on glucose and fat metabolism

D.S. Edgerton<sup>1</sup>, M. Scott<sup>1</sup>, J. Roop<sup>1</sup>, D. Neal<sup>1</sup>, P. Williams<sup>1</sup>, T.B. Kjeldsen<sup>2</sup>, P. Madsen<sup>2</sup>, H. Naver<sup>2</sup>, C.B. Jeppesen<sup>2</sup>, E. Nishimura<sup>2</sup>, C.L. Brand<sup>2</sup>, A.D. Cherrington<sup>1</sup>;

<sup>1</sup>Molecular Physiology and Biophysics, Vanderbilt University School of Medicine, Nashville, USA, <sup>2</sup>Novo Nordisk, Copenhagen, Denmark.

**Background and aims:** Endogenous insulin secretion exposes the liver to concentrations of insulin which are ~2.5-fold greater than at non-hepatic tissues. Subcutaneous insulin delivery eliminates this gradient and is associated with metabolic abnormalities. Thus, restoring the physiologic gradient may provide a therapeutic benefit. The hepato-selectivity of a novel insulin analog (insulin 327) was tested.

**Materials and methods:** Dogs with arterial, portal vein and hepatic vein catheters were studied after an 18h fast. 3H-glucose was infused from -140 min. After a basal period (-40 to 0 min) somatostatin and basal portal glucagon were infused (0 to 300 min). At the same time insulin 327 or human insulin (HI) was infused into a peripheral vein (7.2 or 1.8 pmol/kg/min, respectively;  $n=5$ /group) and euglycemia was maintained by glucose infusion.

**Results:** Arterial insulin 327 and HI levels increased to  $10870 \pm 2543$  and  $95 \pm 8$  pmol/l, respectively. Although the glucose infusion rates were similar in insulin 327 and HI ( $3.1 \pm 0.3$  vs  $3.1 \pm 1.6$  mg/kg/min, respectively, last 3h), insulin 327 had a greater effect on the liver and a lesser effect on non-hepatic tissues compared to HI. Relative to the basal period, insulin 327 suppressed net hepatic glucose balance and glucose Ra (mg/kg/min; last 3h) by  $1.9 \pm 0.1$  and  $1.7 \pm 0.1$ , respectively, while HI reduced these by only  $0.5 \pm 0.6$  and  $1.1 \pm 0.3$ . On the other hand, insulin 327 only increased non-hepatic glucose uptake and glucose Rd (mg/kg/min; last 3h) by  $1.0 \pm 0.4$  and  $1.5 \pm 0.3$ , respectively, while HI increased these by  $2.4 \pm 1.2$  and  $2.5 \pm 1.1$ . Suppression of lipolysis was delayed with insulin 327 compared to HI: during the 1st hour plasma NEFA levels ( $\mu\text{mol/l}$ ) decreased by  $91 \pm 37$  vs  $419 \pm 42$ , respectively, and blood glycerol levels ( $\mu\text{mol/l}$ ) fell by  $0 \pm 7$  vs  $39 \pm 5$ , respectively. During the last 3h, however, there were no differences in the suppression of lipolysis by insulin 327 compared to HI.

**Conclusion:** These results demonstrate the efficacy of a peripherally delivered insulin analog designed to preferentially target liver glucose metabolism.

#### Two phase 3 trials of 3-times weekly insulin degludec versus once-daily insulin glargine in insulin-naïve people with type 2 diabetes

J.H. DeVries<sup>1</sup>, R.E. Ratner<sup>2</sup>, B.W. Bode<sup>3</sup>, D.L. Russell-Jones<sup>4</sup>, K. Begtrup<sup>5</sup>, T. Johansen<sup>5</sup>, B. Zinman<sup>6</sup>;

<sup>1</sup>Academic Medical Center, Amsterdam, Netherlands, <sup>2</sup>MedStar Health Research Institute, Hyattsville, USA, <sup>3</sup>Atlanta Diabetes Associates, Atlanta, USA, <sup>4</sup>Royal Surrey County Hospital, Guildford, UK, <sup>5</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>6</sup>Samuel Lunenfeld Research Institute, Toronto, Canada.

**Background and aims:** Insulin degludec (IDeg) is an ultra-long-acting basal insulin with a half-life of ~25 h (twice that of insulin glargine (IGlar)) and a consistent action profile of >42 h. Based on these characteristics, a 3-times weekly dosing regimen (3TW) was explored in a treat-to-target phase 2 trial in patients with type 2 diabetes (T2D) where IDeg 3TW was as safe and efficacious as once-daily IGlar (IGlar OD). Here we present results of two phase 3 trials designed to further evaluate efficacy and safety of IDeg 3TW.

**Materials and methods:** In two 26-week, open-label, non-inferiority, treat-to-target trials in insulin-naïve subjects with T2D, IDeg was injected Mon, Wed & Fri before the first meal of the day (3TW AM: Trial 1) or from evening meal to bedtime (3TW PM: Trial 2), and compared with IGlar OD (dosed the same time each day as per label). In total, 927 subjects (mean: age  $57.7 \pm 10$  yrs,  $\text{HbA}_{1c}$   $8.3 \pm 0.8\%$ , diabetes duration  $8.8 \pm 6.1$  yrs, BMI  $32.3 \pm 5.3$  kg/m<sup>2</sup>) were randomised (1:1) to IDeg 3TW or IGlar OD, combined with metformin +/- DPP-4 inhibitors. Starting doses were 10 U/day (IGlar OD) or 20 U/injection (IDeg 3TW); doses were titrated to FPG <5 mmol/L using a common algorithm (IDeg 3TW dose adjustments were twice those of IGlar OD).

**Results:** IDeg 3TW and IGlar OD decreased  $\text{HbA}_{1c}$  from baseline by 1.0-1.1% and 1.4%, respectively. However, non-inferiority was not confirmed

(3TW AM-IGlar OD: 0.34% [0.18; 0.51]95%CI; 3TW PM-IGlar OD: 0.26% [0.11; 0.41]); thus, the primary outcome was not achieved. For IDeg 3TW, pre-breakfast SMPG levels gradually increased with time since last injection (Table). At Week 26, calculated mean insulin utilization was 50–51 U/day (IDeg 3TW) and 56–62 U/day (IGlar OD). Overall rates of confirmed hypoglycaemia (PG <3.1 mmol/L or requiring assistance) were 1.0–1.6 episodes per patient-yr of exposure (PYE) and similar for 3TW AM and IGlar OD (estimated rate ratio: 1.04 [0.69; 1.55]), but higher for 3TW PM vs. IGlar OD (1.58 [1.03; 2.43]). Overall rates of nocturnal confirmed hypoglycaemia were 0.2–0.4 episodes per PYE, and similar for 3TW PM and IGlar OD (0.60 [0.21; 1.69]), but higher for 3TW AM vs. IGlar OD (2.12 [1.08; 4.16]). As non-inferiority of HbA<sub>1c</sub> was not obtained, hypoglycaemia results should be interpreted with caution as the difference at similar HbA<sub>1c</sub> may be even greater. In total, 2 severe hypoglycaemic episodes were reported for IDeg 3TW (1 with AM dosing; 1 with PM dosing) vs. 1 episode with IGlar OD.

**Conclusion:** While the clinically relevant reductions in HbA<sub>1c</sub> confirm the ultra-long duration of action of IDeg, the overall benefit to risk relationship in these phase 3 trials does not support a 3TW dosing regimen in this patient population. Thus, IDeg should only be recommended for once-daily use.

	Mean pre-breakfast self-measured PG (mmol/L) - Week 26			
	IDeg 3TW AM	IGlar OD*	IDeg 3TW PM	IGlar OD*
<b>One day since 3TW injection</b> (Tue, Thur, Sat)	5.98	6.07	5.85	5.83
<b>Two days since 3TW injection</b> (Wed, Fri, Sun)	6.91	6.08	6.49	5.84
<b>Three days since 3TW injection</b> (Mon)	7.50	6.05	7.04	5.91

\*IGlar was dosed at the same time each day according to label

### Effect of insulin degludec on glycaemic control and nocturnal hypoglycaemia compared with insulin glargine: a 1-year trial in insulin-naïve patients with type 2 diabetes

**B. Zinman**<sup>1</sup>, A. Philis-Tsimikas<sup>2</sup>, Y. Handelsman<sup>3</sup>, H.W. Rodbard<sup>4</sup>, B. Cariou<sup>5</sup>, T. Johansen<sup>6</sup>, L. Endahl<sup>6</sup>, C. Mathieu<sup>7</sup>

<sup>1</sup>Samuel Lunenfeld Research Institute, Toronto, Canada, <sup>2</sup>Scripps Whittier Diabetes Institute, La Jolla, USA, <sup>3</sup>Metabolic Institute of America, Tarzana, USA, <sup>4</sup>Endocrine and Metabolic Consultants, Rockville, USA, <sup>5</sup>Department of Endocrinology, Nantes University Hospital, Nantes, France, <sup>6</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>7</sup>UZ Gasthuisberg, KU Leuven, Belgium.

**Background and aims:** Insulin degludec (IDeg) is a novel basal insulin with an ultra-long, flat action profile. The objective of this 52-week randomised, open-label, non-inferiority, treat-to-target trial was to compare the efficacy and safety of IDeg to insulin glargine (IGlar) given s.c. once daily in insulin-naïve patients with type 2 diabetes inadequately controlled with oral antidiabetic drugs (metformin±dipeptidyl peptidase-4 inhibitor).

**Materials and methods:** 1030 adults (mean age 59.1 years; diabetes duration 9.2 years; baseline HbA<sub>1c</sub> 8.2%; fasting plasma glucose [FPG] 9.7 mmol/L) were randomised 3:1 to IDeg or IGlar. Both basal insulins were titrated to achieve self-measured blood glucose targets calibrated to PG of 3.9–4.9 mmol/L.

**Results:** Patient completion rates were 79% (IDeg) and 77% (IGlar). At 1 year, IDeg reduced HbA<sub>1c</sub> (−1.06%) non-inferior to IGlar (−1.19%) (estimated treatment difference [ETD] IDeg-IGlar: 0.09% [95% CI: −0.04; 0.22]). FPG reductions were significantly larger with IDeg than IGlar (−3.76 vs. −3.30 mmol/L; ETD: −0.43 mmol/L [95%CI: −0.74; −0.13];  $p=0.005$ ). Overall confirmed hypoglycaemia (PG <3.1 mmol/L and severe episodes requiring assistance) rates were similar for IDeg and IGlar (1.52 vs. 1.85 episodes/patient-year; estimated rate ratio [ERR] IDeg:IGlar 0.82 [95% CI: 0.64; 1.04];  $p=0.11$ ). Overall severe hypoglycaemia was infrequent but significantly lower with IDeg (0.003 vs. 0.023 episodes/patient-year; ERR IDeg:IGlar 0.14 [95% CI: 0.03; 0.70];  $p=0.02$ ). Nocturnal confirmed hypoglycaemia rates were significantly 36% lower with IDeg (0.25 vs. 0.39 episodes/patient-year; ERR IDeg:IGlar 0.64 [95% CI: 0.42; 0.98];  $p=0.04$ ). End-of-trial mean daily insulin

doses were 0.59 (IDeg) and 0.60 (IGlar) U/kg. Mean weight gain was similar: 2.4 kg for IDeg and 2.1 kg for IGlar. Overall adverse event rates were low and similar between groups.

**Conclusion:** In this treat-to-target trial with insulin-naïve patients with type 2 diabetes, IDeg and IGlar provided similar long-term glycaemic control, with significantly lower rates of nocturnal hypoglycaemia with IDeg.

### Insulin degludec is superior to sitagliptin in improving glycaemic control in uncontrolled patients with type 2 diabetes on oral agents

**A. Philis-Tsimikas**<sup>1</sup>, S. Del Prato<sup>2</sup>, I. Satman<sup>3</sup>, A. Bhargava<sup>4</sup>, M. Dharmalingam<sup>5</sup>, T.V. Skjøth<sup>6</sup>, S. Rasmussen<sup>6</sup>, A.J. Garber<sup>7</sup>

<sup>1</sup>Scripps Whittier Diabetes Institute, La Jolla, USA, <sup>2</sup>Department of Endocrinology and Metabolism, University of Pisa, Italy, <sup>3</sup>Istanbul University, Istanbul Faculty of Medicine, Turkey, <sup>4</sup>Iowa Diabetes & Endocrinology Research Center, Des Moines, USA, <sup>5</sup>Bangalore Endocrinology & Diabetes Research Center, India, <sup>6</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>7</sup>Department of Medicine, Baylor College of Medicine, Houston, USA.

**Background and aims:** Insulin degludec (IDeg) is an ultra-long-acting basal insulin with a stable glucose-lowering action profile. The aim of this study was to compare IDeg to sitagliptin (Sita), a dipeptidyl peptidase-4 inhibitor, in insulin-naïve patients with type 2 diabetes who were inadequately controlled with oral antidiabetic drugs (OADs).

**Materials and methods:** In this 26-week, open-label trial 458 insulin-naïve adults with type 2 diabetes (mean age 56 years, diabetes duration 7.7 years, baseline HbA<sub>1c</sub> 8.9% [73.8 mmol/L], fasting plasma glucose [FPG] 9.7 mmol/L [175 mg/dL]) were randomised (1:1) to once-daily IDeg (n=229) or Sita (100 mg orally; n=229) as add-on to stable treatment with one or two OADs (metformin, sulphonylureas, glinides or pioglitazone). IDeg was dosed between wake-up and bedtime based on each individual's preference.

**Results:** The completion rate was 76% in both treatment arms. At 26 weeks, IDeg was superior to Sita in reducing HbA<sub>1c</sub>; (estimated treatment difference [ETD] IDeg-Sita: −0.43% points, [95% CI: −0.61, −0.24;  $p<0.0001$ ] with observed mean reductions of 1.56% vs. 1.22%-points, respectively). HbA<sub>1c</sub> <7% (53 mmol/mol) was achieved by 41% (IDeg) versus 28% (Sita) of patients, estimated odds ratio IDeg:Sita 1.60 [1.04, 2.47;  $p=0.034$ ]. IDeg was superior to Sita in reducing FPG (ETD IDeg-Sita: −2.17 mmol/L [−2.59, −1.74;  $p<0.0001$ ] with observed mean reductions of 3.22 versus 1.39 mmol/L (58 vs. 25 mg/dL), respectively. Despite the lower FPG, there was no statistically significant difference in the rate of nocturnal confirmed hypoglycaemia (PG <3.1 mmol/L [56 mg/dL] or ADA-defined severe episodes from 00:01 to 05:59) between IDeg and Sita (0.52 vs. 0.30 episodes/patient-year, estimated rate ratio (ERR) IDeg:Sita 1.93 [0.90, 4.10;  $p=0.09$ ]). Rates of overall confirmed hypoglycaemia were higher with IDeg than with Sita (3.1 vs. 1.3 episodes/patient-year, ERR IDeg:Sita 3.81 [2.40, 6.05;  $p<0.0001$ ]); one severe episode was reported with IDeg. IDeg was associated with a larger weight gain than Sita: ETD IDeg-Sita 2.75 kg [1.97, 3.54;  $p<0.0001$ ]. The rate of adverse events was low for both groups.

**Conclusion:** IDeg was superior to Sita in improving glycaemic control; overall hypoglycaemia was higher with IDeg, but there was no difference in severe or nocturnal hypoglycaemia. Initiating IDeg in insulin-naïve patients is an effective and well-tolerated alternative to an additional OAD in patients with type 2 diabetes.

## 41

### Human hyaluronidase + rapid analogue insulin (RAI) improves postprandial glycaemic control in type 1 diabetes compared to insulin lispro alone

**J.S. Skyler**<sup>1</sup>, S. Garg<sup>2</sup>, I.B. Hirsch<sup>3</sup>, T. Blevins<sup>4</sup>, D.E. Vaughn<sup>5</sup>, D.B. Muchmore<sup>5</sup>

<sup>1</sup>University of Miami, <sup>2</sup>University of Colorado Denver, Aurora, <sup>3</sup>University of Washington, Seattle, <sup>4</sup>Texas Diabetes and Endocrinology, Austin, <sup>5</sup>Halozyyme Therapeutics, San Diego, USA.

**Background and aims:** Recombinant human hyaluronidase (rHuPH20) accelerates absorption & action of prandial insulins and also reduces postpran-

dial glycemic excursions following liquid test meal administration without increasing risk of hypoglycemia. Our objective was to compare glucose control in T1DM using prandial lispro or RAI+rHuPH20 (Analog-PH20) in the outpatient treatment setting.

**Materials and methods:** After a 4–6 week run-in using prandial glulisine + bid glargine, 117 subjects (age  $43 \pm 14$  years, BMI  $27.3 \pm 4.0$  kg/m<sup>2</sup>, A1C  $7.0 \pm 0.5\%$ ) were randomized (double blind 2-way crossover) to lispro+rHuPH20 or aspart+rHuPH20 vs lispro alone for two 12 week intensive management periods; prandial doses were immediately before meals. The primary endpoint was A1C noninferiority (0.4% margin); postprandial excursions were measured by self monitoring of blood glucose (SMBG) and also by continuous glucose monitoring. Overall hypoglycemia was self-reported as SMBG  $\leq 3.9$  mmol/l or symptoms.

**Results:** Changes from baseline A1C were comparable ( $-0.14\%$  for Analog-PH20;  $-0.19\%$  for lispro), with no significant treatment difference (95% CI  $-0.05, +0.15$ ). At the end of treatment, fasting glucose values were comparable between treatments (Analog-PH20  $7.85 \pm 2.23$  mmol/l vs lispro  $7.90 \pm 2.34$  mmol/l;  $p=.86$ ). Mean postmeal (90 min) excursions were reduced by 82% ( $p=.0045$ ) over the 12 week period with more subjects consistently (at least 2/3 of meals) achieving values  $<10$  mmol/l at breakfast (70.5% vs 54.0%,  $p=.003$ ),  $<10$  mmol/l at all meals (70.8% vs 59.3%,  $p=.016$ ),  $<7.8$  mmol/l at breakfast (21.4% vs. 10.6%,  $p=.007$ ) and  $<7.8$  mmol/l at all meals (15.0% vs 8.8%,  $p=.089$ ). Continuous monitoring over 3 days at the end of treatment showed improved excursion profiles (Figure). The overall hypoglycemia ( $\leq 3.9$  mmol/l or symptoms) rate during the treatment was reduced 5% during Analog-PH20 treatment, from 19.9 to 19.0 episodes per subject-month ( $p=.035$ ) and events  $<3.1$  mmol/l were reduced 7%, from 8.05 to 7.50 per subject-month ( $p=.044$ ). Total daily insulin dose ( $54 \pm 27$  for Analog-PH20 vs  $56 \pm 27$  U for lispro,  $p=.057$ ) and weight gain difference ( $-.26$  kg,  $p=.27$ ) showed favorable trends. Adverse events were comparable between treatments and Analog-PH20 was well tolerated. Immunogenicity results showed 13 subjects with pre-existing anti-rHuPH20 antibodies; 3 subjects developed *de novo*, low titer anti-rHuPH20 antibodies without any associated adverse events.

**Conclusion:** Compared to insulin lispro alone, coformulation of RAI+rHuPH20 improves postprandial glycemic excursions and hypoglycemia risks while maintaining comparable A1C outcomes in an intensive diabetes treatment program.

### LY2605541: Leveraging hydrodynamic size to develop a novel basal insulin

J.M. Beals<sup>1</sup>, G.B. Cutler, Jr.<sup>2</sup>, A. Vick<sup>2,3</sup>, A. Koester<sup>1</sup>, S. Li<sup>1</sup>, A.M. Siesky<sup>1</sup>, R.J. Hansen<sup>1</sup>

<sup>1</sup>Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, <sup>2</sup>formerly of Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, <sup>3</sup>Seventh Wave Laboratories, Chesterfield, USA.

**Background and aims:** Improvements in basal insulins have focused primarily on slowing subcutaneous (SC) release; however, exogenously administered insulin is prone to glomerular filtration and therefore to significant renal clearance. To develop the novel basal insulin analog (LY2605541 [LY]) with the goal of both slowing SC absorption and reducing renal clearance, insulin lispro was site-specifically and covalently modified with a 20-kDa polyethylene glycol (PEG) moiety at lysine B28, via a covalent urethane bond, increasing the hydrodynamic size. LY was also given to 5/6 nephrectomized rats (10 nmol/kg, intravenous injection) to assess the impact of renal impairment on LY clearance.

**Materials and methods:** The hydrodynamic diameter was determined using an ALV/CGS-3 Compact Goniometer system with ALV/LSE-5003 Light Scattering Electronics and Multiple Tau Digital Correlator. LY and insulin lispro were formulated under monomeric conditions with a target concentration of  $\sim 0.5$  mg/mL (to minimize non-ideality) in PBS (pH 7.4) at 298.15K. All sample viscosities were measured at 25°C. Hydrodynamic diameters were derived using the Stokes-Einstein equation. PK/PD studies were conducted in STZ-induced diabetic rats. LY was given as a single subcutaneous injection at doses ranging from 9.4–568 nmol/kg. LY concentrations were determined via immunoassay and glucose levels were determined by glucometer. Allometric scaling was used to project human PK parameters and to simulate once-daily dosing. The 5/6 nephrectomized studies were conducted in Sprague Dawley male rats that underwent a two part surgery (surgeries separated by 1 week; N = 8–10). Blood samples were collected by three methods (retro-orbital bleeds, tail bleeds, or cardiac stick) depending on each test article's time point. Clearance differences were compared to sham controls.

**Results:** Dynamic light scattering analysis indicated that PEGylated insulin lispro (LY) had a hydrodynamic diameter of  $7.9 \pm 0.5$  nm, a diameter 4x larger than insulin lispro and analogous to the size of a  $\sim 75$ kDa globular protein. In rats treated with streptozotocin to induce diabetes, LY's increased hydrodynamic size resulted in a robust dose response profile with slowed absorption from the SC site, exemplified by a shift in  $T_{max}$  ( $\sim 25$ x), and reduced clearance ( $\sim 10$ x) with concomitant glucose-lowering properties. Comparing 5/6th nephrectomized rats with sham controls, no renal clearance differences were observed with LY whereas insulin lispro clearance was reduced. Based upon these preclinical PK/PD data, human plasma profiles were modeled for once-daily dosing of LY. The model predicted gradual attainment of steady-state plasma LY levels with a peak-to-trough ratio of  $<1.5$ .

**Conclusion:** LY2605541 was designed to have a large hydrodynamic size which slows insulin absorption and reduces renal clearance. LY demonstrated prolonged duration of action in preclinical studies. These effects formed the basis for further pursuit of LY as a novel basal insulin, wherein subsequent development confirmed the prolonged PK/PD profile in Phase 1–2 studies.

### Manifestation of neuropathy in the corneal nerve plexus correlates with hyperglycaemia and increased advanced glycation end products

M. Reichard<sup>1</sup>, H. Weiss<sup>2</sup>, R. Waterstradt<sup>2</sup>, M. Tiedge<sup>2</sup>, O. Stachs<sup>1</sup>, S. Baltrusch<sup>2</sup>,  
<sup>1</sup>Department of Ophthalmology, <sup>2</sup>Institute of Medical Biochemistry and Molecular Biology, University of Rostock, Germany.

**Background and aims:** The most common long-term complication of diabetes mellitus (DM) is the diabetic neuropathy, unfortunately diagnosed at an advanced stage when irreversible damage has already developed. In-vivo confocal laser scanning microscopy (CLSM) facilitates the early examination of alterations in the corneal nerve plexus. However, there is a lack of longitudinal studies dealing with this non-invasive ophthalmic marker in correlation to metabolic parameters in DM. Therefore the aim of this study was to investigate the corneal nerve structure in diabetic and healthy NOD mice by CLSM together with a metabolic characterization of the animals.

**Materials and methods:** The NOD mice were characterised by measuring blood glucose (BG) and glycated HbA<sub>1c</sub>. Advanced glycation end products (AGEs) were determined by ELISA. For CLSM the animals were anesthetized and fixed to avoid movement. The eye was moistened with a carbomer gel and the cornea was visualised using the HRTII + RCM system. Images were quantified for nerve fibre density (NFD) using NeuronJ (ImageJ). Finally the animals were killed and organs were removed for RNA preparation. Expression of the receptor of AGEs (RAGE) was quantified by RT-PCR.

**Results:** Diabetic NOD mice showed at the age of 36 weeks a twofold higher AGEs concentration, and significant alterations in the corneal nerve plexus in comparison to their healthy littermates (n = 10). Mice were monitored over one year with weekly BG measurements. Healthy animals showed mean BG and HbA<sub>1c</sub> concentrations of  $5.6 \pm 0.1$  mmol/l and  $4.1 \pm 0.1$  %, respectively. In healthy animals a NFD of  $19.4 \pm 1.2$  mm/mm<sup>2</sup> was quantified from CLSM image using a semi-automated analysis approach. During diabetes manifestation the BG and HbA<sub>1c</sub> concentration significantly increased ( $17.3 \pm 1.1$  mmol/l and  $11.1 \pm 0.4$  %) whereas inversely a significant decrease in the NFD was observed by CLSM ( $7.0 \pm 0.3$  mm/mm<sup>2</sup>). Diabetic animals (n = 5) were treated with insulin pellets, which were implanted in the subcutaneous fat. The resulting decrease in the BG concentration was reflected in a reduced HbA<sub>1c</sub> concentration ( $7.8 \pm 0.4$  %). The NFD increased in answer to the therapy, but did not recover to the value before diabetes manifestation ( $12.3 \pm 0.2$  mm/mm<sup>2</sup>). Withdrawal of insulin therapy resulted in accelerated NFD loss. In cornea the expression of RAGE was significantly threefold higher than in palaeocortex, cerebellum, cortex, hippocampus, and liver, and further up-regulated in diabetic animals.

**Conclusion:** We could demonstrate for the first time a causal nexus between the increase in BG and AGEs, and the decrease in the corneal nerve plexus. Binding of AGEs to RAGE initiate oxidative stress eventually disable neuronal regeneration and facilitate neuronal dysfunction. The high RAGE expression in the cornea may explain the high susceptibility of the cornea to hyperglycaemia and the early development of neuronal degeneration. Our study indicates that the in-vivo CLSM of the cornea is a valuable early diagnostic criterion of DM.

### Early detection of nerve fibre loss by corneal confocal microscopy and skin biopsy in recently diagnosed type 2 diabetic subjects

D. Ziegler<sup>1,2</sup>, A. Zhivov<sup>3</sup>, S. Allgeier<sup>4</sup>, K. Winter<sup>5</sup>, N. Papanas<sup>1</sup>, I. Ziegler<sup>1</sup>, J. Brüggemann<sup>1</sup>, S. Peschel<sup>3</sup>, B. Köhler<sup>4</sup>, O. Stachs<sup>3</sup>, R.F. Guthoff<sup>2</sup>, M. Roden<sup>1,2</sup>, for the GDS Group;

<sup>1</sup>Institute for Clinical Diabetology, German Diabetes Center at Heinrich Heine University, Düsseldorf; <sup>2</sup>Department of Metabolic Diseases, University Hospital, Düsseldorf; <sup>3</sup>Department of Ophthalmology, University of Rostock; <sup>4</sup>Institute for Applied Computer Science and Automation, Karlsruhe Institute of Technology; <sup>5</sup>Translational Centre for Regenerative Medicine, University of Leipzig, Germany.

**Background and aims:** Corneal confocal laser scanning microscopy (CCM) has emerged as a noninvasive in vivo technique to quantify the subbasal

nerve plexus (SNP), but it is unclear whether it allows for detection of small nerve fibre pathology at early stages of type 2 diabetes.

**Materials and methods:** We assessed parameters of CCM, corneal sensation, and peripheral nerve function in 86 patients with recently diagnosed type 2 diabetes (71% male, age:  $57.8 \pm 9.1$  [mean $\pm$ SD] years, diabetes duration:  $2.1 \pm 1.8$  years, BMI:  $31.1 \pm 5.7$  kg/m<sup>2</sup>, HbA<sub>1c</sub>:  $6.8 \pm 1.1$ %) and 48 control subjects (65% male, age:  $53.7 \pm 13.4$  years). Intraepidermal nerve fibre density (IENFD) was assessed by immunohistochemistry using PGP 9.5 antibody in 3-mm punch biopsies from the distal leg. Peripheral and autonomic nerve function was quantified by motor and sensory nerve conduction velocity (MNCV, SNCV), sensory nerve action potential (SNAP) amplitudes, vibration perception thresholds (VPT), thermal detection thresholds (TDT), cardiovascular autonomic testing, and pupilligraphy. Image data acquired from automatic CCM focus scans were processed with novel digital image processing algorithms to eliminate motion artifacts and reconstruct images of the SNP devoid of anterior corneal mosaic deformations. Nerve fibres were segmented and analyzed by newly developed software.

**Results:** Corneal nerve fibre density (CNFD) was reduced in patients with diabetes ( $0.0196 \pm 0.007$  vs. control:  $0.0241 \pm 0.007$   $\mu$ m/ $\mu$ m<sup>2</sup>;  $P < 0.001$ ) as were nerve branch density ( $250 \pm 136$  vs.  $327 \pm 171$  mm/m<sup>2</sup>;  $P = 0.008$ ), number of connecting points ( $35.7 \pm 19.0$  vs.  $45.6 \pm 20.0$  mm/m<sup>2</sup>;  $P = 0.005$ ), and nerve fibre thickness ( $2.69 \pm 0.39$  vs.  $2.84 \pm 0.36$   $\mu$ m;  $P = 0.032$ ). CNFD and IENFD were reduced below the 5th percentile in 17% and 18% of the diabetic patients, respectively. However, the vast majority of the patients with abnormal CNFD or IENFD showed concomitantly normal CNFD and abnormal IENFD and vice versa. Either CNFD or IENFD or both parameters were reduced in 34% of the diabetic subjects. In the entire population, CNFD correlated with IENFD ( $r = 0.23$ ;  $P = 0.014$ ), but not with the peripheral, cardiovascular autonomic, and pupillary nerve function tests. In contrast, IENFD correlated significantly with MNCV, SNCV, SNAP amplitudes, TDT, with the closest correlations ( $r > 0.25$ ) being found for sural SNCV and SNAP, median MNCV, and cold TDT on the foot. No difference was noted between patients and controls for corneal sensation.

**Conclusion:** Corneal confocal microscopy detects early nerve fibre loss in recently diagnosed type 2 diabetes, but not necessarily in the same patients as skin biopsy, suggesting a patchy manifestation pattern of small fibre neuropathy in different organs.

45

### Evidence of grey matter atrophy in diabetic neuropathy: a magnetic resonance imaging brain volumetric study

D. Selvarajah<sup>1</sup>, M. Maxwell<sup>1</sup>, J. Davies<sup>1</sup>, A. Sankar<sup>1</sup>, E. Cachia<sup>2</sup>, R. Gandhi<sup>1</sup>, I. Wilkinson<sup>2</sup>, S. Tesfaye<sup>2</sup>;

<sup>1</sup>Diabetes Research Unit, <sup>2</sup>University of Sheffield, UK.

**Background and aims:** Diabetes contributes to accelerated brain atrophy with deleterious effects on cognition leading to dementia. Although the exact mechanisms of brain atrophy remain unknown, chronic metabolic and vascular changes are thought to play an important role. We have previously demonstrated early spinal cord atrophy in subjects with diabetic neuropathy (DN). The aim of this study was to investigate if subjects with DN have evidence of increased brain atrophy.

**Materials and methods:** Forty eight subjects with type 1 diabetes [No-DN (n=22), Painful-DN (n=14), Painless-DN (n=12),] underwent detailed clinical and neurophysiological assessment to quantify the severity of DPN [NIS(LL)+7 tests]. The severity of diabetic retinopathy (DR) was scored from annual eye screening retinal photography. This was used to quantify the severity of microangiopathy. All subjects, including 17 healthy volunteers (HV), underwent volumetric (0.8x0.8x0.8mm<sup>3</sup> resolution) brain magnetic resonance imaging at 3T. Images were analysed using FSL (fMRIB, Oxford, UK); a library of analysis tools for brain imaging data. Peripheral and deep grey matter volumes were calculated using the SIENAX and FIRST tools.

**Results:** All groups were matched for gender. There were significant differences in age [HV 48.6(14.3), No-DN 37.3(10.7), Painless DN 51.4(11.2), Painful-DN 45.8(12.4); ANOVA,  $p = 0.004$ ] and DR score (diabetes groups only;  $p = 0.004$ ) between groups. Group mean differences we examined using a random effects model using age, gender and DR score as covariates (ANCOVA). Painful-DN [760(388) ml] and Painless-DN [767(209) ml] had the lowest total grey matter volume compared to No-DN [812(471) ml] and HV [798(554) ml;  $p = 0.01$ ]. The distribution of brain atrophy was mainly peripheral [HV 631(464) ml, No-DN 640(372) ml, Painful-DN 601(337) ml and Painless DN 605(163) ml;  $p = 0.02$ ] with relative sparing of deep grey matter volume [HV 167(133) ml, No-DN 171(123) ml, Painful-DN 159(101) ml and Painless DN 162(95) ml;  $p = 0.14$ ]. There were no significant differences in white matter

volume ( $p=0.90$ ) and ventricular cerebrospinal fluid volume ( $p=0.40$ ) across the study groups. No significant differences were found between Painful and Painless-DN groups.

**Conclusion:** Our findings suggest the presence of increased peripheral grey matter atrophy in both painful and painless DN. This appears independent of microangiopathy and possibly highlights an important role of the neuro-pathic process in contributing to brain atrophy. This study also provides us with new insights into the extent of central nervous system involvement in DN and may have important implications to its long term prognosis.

### Altered brain microstructure assessed by diffusion tensor imaging in patients with diabetes mellitus and gastrointestinal symptoms

E. Søfteland<sup>1,2</sup>, J.B. Frøkjær<sup>3,4</sup>, L.W. Andersen<sup>3</sup>, G. Dimcevski<sup>1,2</sup>, C. Brock<sup>4</sup>, M. Simrén<sup>5</sup>, A.M. Drewes<sup>4</sup>

<sup>1</sup>Department of Medicine, Haukeland University Hospital, Bergen, Norway,

<sup>2</sup>Institute of Medicine, University of Bergen, Norway, <sup>3</sup>Department of

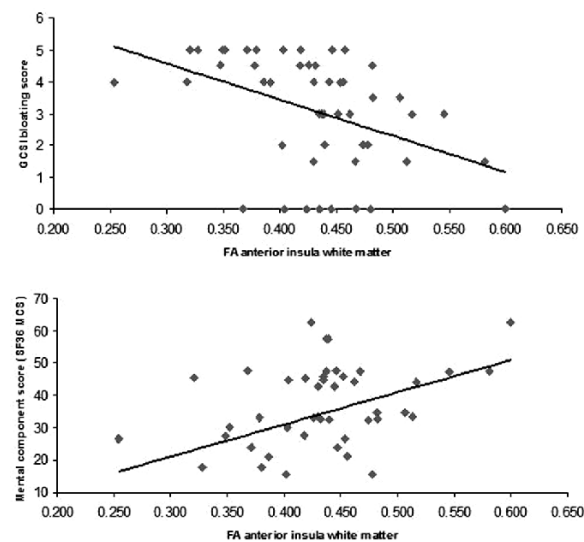

Radiology, Aalborg Hospital, Denmark, <sup>4</sup>Department of Gastroenterology & Hepatology, Aalborg Hospital, Denmark, <sup>5</sup>Institute of Medicine, University of Gothenburg, Sweden.

**Background and aims:** In patients with longstanding diabetes mellitus (DM) there is increasing evidence of abnormal processing of gastrointestinal sensations in the central nervous system. Using magnetic resonance (MR) diffusion tensor imaging, we aimed to characterize brain microstructure in areas involved in visceral sensory processing and correlated these findings to clinical parameters.

**Materials and methods:** Twenty-six patients with DM and gastrointestinal symptoms and 23 healthy controls were studied in a 3 Tesla MR scanner. Apparent diffusion coefficient (ADC) (i.e. diffusivity of water) and fractional anisotropy (FA) (i.e. organization of fibres) values were assessed in the “sensory matrix”: cingulate cortex, insula, prefrontal and secondary sensory cortex, amygdala and corona radiata. Corpus callosum served as control area.

**Results:** Patients had decreased FA values compared to controls in 1) anterior ( $P<0.001$ ), mid ( $P=0.002$ ) and posterior ( $P<0.001$ ) cingulate cortex, 2) prefrontal cortex grey matter ( $P<0.001$ ), 3) corona radiata ( $P<0.001$ ), 4) secondary sensory cortex ( $P=0.005$ ), 5) anterior white matter ( $P=0.048$ ), anterior grey matter ( $P=0.013$ ) and posterior grey matter ( $P<0.001$ ) insula. No difference between the two groups were found in corpus callosum ( $P>0.05$ ). The microstructural changes were for some areas correlated to clinical parameters such as bloating (anterior insula), mental wellbeing (anterior insula, prefrontal cortex, mid cingulate and corona radiata), autonomic function based on electrocardiographic results (posterior insula and anterior cingulate), and the presence of gastroparesis (anterior insula).

**Conclusion:** Our findings suggest that microstructural changes of brain areas involved in visceral sensory processing are correlated to autonomic dysfunction and might be involved in the pathogenesis of gastrointestinal symptoms in diabetes patients.

### Severe symptomatic diabetic gastroparesis in type 1 and type 2 diabetes: ghrelin receptor agonist treatment improves symptoms

N. Ejskjaer<sup>1</sup>, R. Malik<sup>2</sup>, L. Tarnow<sup>3</sup>, P. Hellstrom<sup>4</sup>, G. Dimcevski<sup>5</sup>, J. Pezullo<sup>6</sup>, L. Shaughnessy<sup>6</sup>, R. Venuti<sup>6</sup>, P. Charlton<sup>6</sup>, G. Kosutic<sup>6</sup>, R. McCallum<sup>7</sup>

<sup>1</sup>Department of Medicine M (Endo+Diab), Aarhus University Hospital, Denmark, <sup>2</sup>Division of Cardiovascular Medicine, Manchester Royal Infirmary, UK, <sup>3</sup>Clinical Research Department, Steno Diabetes Center, Copenhagen, Denmark, <sup>4</sup>Department of Gastroenterology, Karolinska, Stockholm, Sweden, <sup>5</sup>Department of Gastroenterology, Haukeland University Hospital, Bergen, Norway, <sup>6</sup>Tranzyme Ltd, Durham, USA, <sup>7</sup>Health Sciences Center, Texas Tech University, Lubbock, USA.

**Background and aims:** Diabetic gastroparesis without symptoms is highly prevalent in both Type 1 and Type 2 diabetes, but is fortunately rare in its most severe form encompassing constant nausea, vomiting, postprandial fullness and bloating. The aim of this study was to characterize the effects of a ghrelin receptor agonist on symptoms of gastroparesis and to determine whether type 1 and type 2 diabetic patients responses are different.

**Materials and methods:** 92 patients {females 65%; age  $49.9 \pm 11.9$  years; 91% Caucasian; BMI  $28.8 \pm 5.1$ ; 60% type 1; HbA1c  $8.3 \pm 1.5\%$ ; PAGI-SYM  $3.0 \pm 0.8$ ; breath test t1/2 GE  $193 \pm 51$  min} suffering delayed gastric emptying and upper gastrointestinal symptoms were randomized to 10, 20 or 40 mg ghrelin receptor agonist or placebo. Symptoms were evaluated by patient-reported symptom severity scales (0-5) on days 8, 15, 28 (treatment) and 42, 58 (follow up). Effects were assessed by changes in symptom scores from baseline compared to end of treatment

**Results:** Significant improvements versus placebo were observed in individual symptoms across all ghrelin receptor agonist dose groups with a maximum improvement at the 20mg dose. Importantly, significant improvement vs. placebo was observed with 20mg ghrelin receptor agonist for each of prevalent symptoms for this patient population; magnitude of the effects was similar in type 1 and type 2 diabetic patients.

**Conclusion:** In our study ghrelin receptor agonist treatment significantly reduced symptoms of severe diabetic gastroparesis in both type 1 and type 2 diabetic patients.

Cruccu<sup>9</sup>, M. Späth<sup>10</sup>, V. Skljarevski<sup>11</sup>, A. Schacht<sup>1</sup>, S. Tesfaye<sup>12</sup>

<sup>1</sup>Lilly Deutschland, Bad Homburg, Germany, <sup>2</sup>Neurologische Klinik und Poliklinik, Technische Universität, München, Germany, <sup>3</sup>Centre d'Évaluation et de Traitement de la Douleur, Hôpital Ambroise Paré, Boulogne Billancourt, France, <sup>4</sup>Médecine Interne, Service de Rhumatologie, Hôpital Hotel Dieu, Université Paris V Descartes, France, <sup>5</sup>Karolinska Institutet, Stockholm, Sweden, <sup>6</sup>Grupo de Investigación y Desarrollo en Neuropsicofarmacol., Universidad de Cadiz, Spain, <sup>7</sup>Departamento de Neurología, Clínica Creu Blanca, Barcelona, Spain, <sup>8</sup>Benedictus Krankenhaus, Tutzing, Germany, <sup>9</sup>Sapienza University, Roma, Italy, <sup>10</sup>Spital Linth, Uznach, Switzerland, <sup>11</sup>Lilly Research Laboratories, Indianapolis, USA, <sup>12</sup>Royal Hallamshire Hospital, Sheffield, UK.

**Background and aims:** There have been no large head-to-head or combination treatment trials in painful diabetic peripheral neuropathic pain (DPNP). The COMBO-DN study primarily investigated the combination of duloxetine (DLX) and pregabalin (PGB) in patients with DPNP not responding to standard doses of each drug. The study also included for the first time, a randomized, double-blind, parallel group comparison of DLX and PGB for initial pain therapy.

**Materials and methods:** DPNP patients with a daily pain score of  $\geq 4$  on the Brief Pain Inventory Modified Short Form (BPI-MSF) were randomly assigned to 8-week initial treatment with either 60 mg DLX/day or 300 mg PGB/day. Efficacy was assessed by the BPI-MSF, Neuropathic Pain Symptom Inventory (NPSI), and Hospital Anxiety and Depression Scale (HADS). Scores were compared using Mixed Model Repeated Measures analyses or analyses of covariance, response rates ( $\geq 50\%$  reduction in BPI-MSF average pain after 8 weeks) by the Cochran-Mantel-Haenszel test. Frequency of

treatment-emergent adverse events (TEAEs) as safety measure was compared using Fisher's exact test.

**Results:** Of 1074 patients screened, 404 were randomized to DLX and 407 to PGB. After 8 weeks of treatment, differences between DLX and PGB were statistically significant in favor of DLX for all BPI-MSF scores, the NPSI total score, and all HADS scores. The least square (LS) mean (standard error [SE]) change from baseline in BPI-MSF average pain was -2.3 (0.11) for DLX vs. -1.7 (0.11) for PGB ( $p<0.001$ ); LS mean (SE) changes in NPSI total score were -19.4 (0.98) vs. -14.7 (0.98) ( $p<0.001$ ), and in HADS total score -3.1 (0.26) vs. 2.1 (0.26), respectively ( $p<0.005$ ). Response rates were 40.3% for DLX vs. 27.8% for PGB ( $p<0.001$ ). Most common TEAEs ( $>10\%$  of all patients) were dizziness (7.2% [DLX] vs. 15.1% [PGB];  $p<0.001$ ), somnolence (10.0% [DLX] vs. 10.9% [PGB];  $p>0.50$ ) and nausea (14.2% [DLX] vs. 6.5% [PGB];  $p<0.001$ ). However, the proportions of patients who discontinued due to TEAEs were not different between both drugs (11.5% [DLX] vs. 12.4% [PGB];  $p>0.50$ ).

**Conclusion:** The COMBO-DN study was the first ever trial directly comparing standard doses of DLX and PGB in DPNP patients. DLX (60 mg/day) was shown to have superior efficacy compared to PGB (300 mg/day). No new safety concerns were identified.

### Effectiveness of oral antidiabetic drugs in treatment naïve patients: trends in HbA<sub>1c</sub> in the UK

A. Maguire<sup>1</sup>, B. Mitchell<sup>2</sup>;

<sup>1</sup>Epidemiology and Database Analytics, UBC, London, UK, <sup>2</sup>Global Outcomes, Eli Lilly, Indianapolis, USA.

**Background and aims:** In the UK, oral antidiabetic therapy (OAD) is indicated for type 2 diabetes (T2D) if life style counselling is ineffective and HbA<sub>1c</sub> remains over 48mmol/mol (6.5%). In 2004, the introduction of the Quality and Outcomes Framework incentivised the systematic recording of measures such as HbA<sub>1c</sub>. The subsequent period has also coincided with increased level of computerised linkage with laboratories. Hence, given the accrued data it is now feasible to evaluate the changes in HbA<sub>1c</sub> over time and provide an insight into the effectiveness of initiating OAD which is the aim of this study.

**Materials and methods:** This is a retrospective cohort study of all new users of OAD between January 2006 and February 2011 identified in primary care practices that participate in the General Practice Research Database (GPRD). The most recent HbA<sub>1c</sub> value measured during the 6 months prior to OAD initiation was assigned as the baseline HbA<sub>1c</sub>. HbA<sub>1c</sub> values were assigned to each year following OAD initiation by selecting the HbA<sub>1c</sub> recorded closest to each time point (i.e., 12, 24, 36 and 48 months after OAD initiation) provided it was measured within 6 months of the time point. HbA<sub>1c</sub> is expressed in mmol/mol; Q1 and Q3 are the lower and upper quartiles.

**Results:** There were 63060 patients initiating OAD in the study period; mean age 62 years, 57% were male and 88% started on metformin. Median follow-up was 729 days (range: 1 to 1879 days). The median HbA<sub>1c</sub> at OAD initiation was 65 (Q1=57; Q3=80; N=43863) which reduced to 52 (Q1=46; Q3=60; N=34737) after one year. The HbA<sub>1c</sub> at subsequent time points was 53 (Q1=46; Q3=61; N=22650) at 2 years; 53 (Q1=48; Q3=62; N=12631) at 3 years; and 54 (Q1=48; Q3=63; N=4383) at 4 years. The mean within patient reduction was 15.8 (Standard Error "SE"=0.1) at one year. There was a slight increase in the within patient change in HbA<sub>1c</sub> for each subsequent year with respect to the previous year's measurement: 0.6 at 2 years (SE=0.1); 0.6 at 3 years (SE=0.1); 0.5 at 4 years (SE=0.2). Despite this reduction most patients remained above the recommended 48 mmol/mol (67% at 12months increasing to 74% at 4 years); similarly 28% were above 58 mmol/mol at 1 year since initiating OAD and 34% at 4 years. Patients with HbA<sub>1c</sub>>58 after 1 year were younger (59 vs. 63 years) and there was a slightly higher proportion of men (61% vs. 56%). Changes in treatment regimen were related to HbA<sub>1c</sub> at one year such that mean HbA<sub>1c</sub> was highest in patients who were augmented with insulin (mean=86) and lowest in patients who maintained their initial regimen (mean=52) or who discontinued therapy (mean=53).

**Conclusion:** This study in a large representative sample of patients with T2D in the UK has shown that there is a substantial reduction in HbA<sub>1c</sub> following OAD initiation. However, most patients remain above recommended levels and there is evidence of a slight increase of HbA<sub>1c</sub> over time. Changes in treatment regimen occur when levels are very high; over half the patient who augmented OAD with insulin had HbA<sub>1c</sub> that were above 80 mmol/mol at 12 months after initiating OAD.

## 50

**The application of genome-wide association data to determine heritability of glycaemic response to metformin**

K. Zhou, C.N.A. Palmer, E.R. Pearson;  
Medical Research Institute, Dundee, UK.

**Background and aims:** Glycaemic response to metformin varies considerably among type 2 diabetes patients. Although robustly replicated loci for metformin response, such as that at the ATM locus, have been discovered it is not known how heritable the trait is. As for most drug response phenotypes, adopting the traditional twin or family study design to estimate metformin heritability is impractical because of the need to have relatives treated with the same drug. Here we report the first estimation of metformin glycaemic response heritability using a method based on genome-wide association data from unrelated patients.

**Materials and methods:** We used 3736 patients from the GoDARTS cohort who were genotyped by the WTCCC2 on the Affymatrix 6 array for pharmacogenomic investigations. Glycaemic response to metformin, measured as the maximum HbA1C reduction achieved within 18 months of treatment start, was definable in 1289 patients. Genetic relationship matrix was estimated with software GCTA using genotypes from 705125 autosomal SNPs. Further filtering was performed to ensure no pairwise genetic relationship  $>0.025$  among these seemingly independent individuals. Heritability was then estimated in a restricted maximum likelihood analysis, with clinical covariates such as baseline HbA1C, adherence and creatinine clearance included as fixed effect linear covariates.

**Results:** Our benchmark studies within the GoDARTS data estimated heritability for height as 28% (S.E.=10%;  $p=0.003$ ;  $n=3373$ ) and age at diagnosis of type 2 diabetes as 25% (S.E.=14%;  $p=0.04$ ;  $n=2497$ ). In the 1117 independent metformin treated patients, 36% (S.E.=32%,  $p=0.15$ ) of glycaemic response variation can be explained by autosomal SNPs.

**Conclusion:** Although more samples are required to quantify the heritability more accurately, our result suggests that metformin glycaemic response is likely to have a strong genetic component, on a par or greater than that seen with height or age of onset of type 2 diabetes.

**Metformin and other glucose-lowering treatments: risks and benefits. Nationwide epidemiological study**

E. Nils<sup>1</sup>, L. Schiöler<sup>2,3</sup>, A.-M. Svensson<sup>2</sup>, K. Eeg-Olofsson<sup>1</sup>, J. Miao Jonasson<sup>2</sup>, B. Zethelius<sup>4</sup>, J. Cederholm<sup>5</sup>, S. Gudbjörnsdottir<sup>1,2</sup>, B. Eliasson<sup>1</sup>;

<sup>1</sup>Department of Medicine, Sahlgrenska Academy at the University of Gothenburg, <sup>2</sup>Center of Registers in Region Västra Götaland, Gothenburg, <sup>3</sup>Department of Public Health and Community Medicine, Sahlgrenska Academy at the University of Gothenburg, <sup>4</sup>Department of Public Health and Caring Sciences/Geriatrics, Uppsala University, <sup>5</sup>Department of Public Health and Caring Sciences/Family Medicine and Clinical Epidemiology, Uppsala University, Sweden.

**Background and aims:** The long-term effectiveness and safety of glucose-lowering medications are under debate. This observational study from the Swedish National Diabetes Register (NDR) evaluates the risks of cardiovascular disease (CVD), lactic acidosis, serious infections and mortality in a large sample of pharmacologically treated patients with type 2 diabetes (DM2) in clinical practice, with particular emphasis on metformin.

**Materials and methods:** Pharmacologically treated DM2 patients registered in the NDR July 1, 2004 - December 31, 2007 were included ( $n=51\,675$ ), and grouped based on treatments. Risks of fatal/non-fatal CVD, acidosis/serious infection and all-cause mortality were analysed in all patients and in subgroups with different estimated glomerular filtration rate (eGFR) intervals. Mean follow-up was 3.9 years, equivalent to more than 200 000 patient-years at risk.

**Results:** Insulin monotherapy showed increased risks of fatal/non-fatal CVD and all-cause mortality compared to metformin monotherapy, hazard ratios (HR) 1.18 (95 % confidence limits: 1.07-1.29) and 1.34 (1.19-1.50), after adjustment with a propensity score including clinical characteristics, risk factors and treatments. In subgroup analyses, adjusted for covariance with similar covariates, metformin was not associated with increased risk of any of the outcomes in patients with eGFR 30-45, 45-60, or  $>60$  mL/min/1.73 m<sup>2</sup> compared to all other hypoglycaemic agents. In the subgroup with eGFR 45-60 mL/min/1.73 m<sup>2</sup>, metformin showed a reduced risk of any acidosis/serious infection, HR 0.85 (0.74-0.97), and all-cause mortality, 0.87 (0.77-0.99).

**Conclusion:** Metformin was associated with reduced risks of severe end-points, using propensity score or covariance adjustment. Results were consistent in patients with renal impairment, with no increased risk of acidosis/serious infection. In clinical practice, the benefits of metformin use clearly outbalance the risk of severe side effects. These results support the less strict approach to metformin use in patients with renal impairment (eGFR 45-60 mL/min/1.73 m<sup>2</sup>), advocated in most guidelines and imply further investigation with randomized clinical trials.

**Figure 1. Time (months) to event of all-cause mortality (a), any CVD (b), and any infection/acidosis (c) in each treatment group, unadjusted**

**Risk of acute coronary syndrome differs with glyburide and gliclazide treatment in patients with type 2 diabetes and ischaemic heart disease: a population-based cohort study**A. Abdelmonem<sup>1</sup>, D.T. Eurich<sup>2</sup>, J.-M. Gamble<sup>3</sup>, J.A. Johnson<sup>2</sup>, J. Seubert<sup>1,4</sup>, W. Qiu<sup>2</sup>, S.H. Simpson<sup>1</sup>;<sup>1</sup>Faculty of Pharmacy and Pharmaceutical Sciences, University of Alberta, Edmonton, <sup>2</sup>School of Public Health, University of Alberta, Edmonton,<sup>3</sup>School of Pharmacy, Memorial University of Newfoundland, St. John's,<sup>4</sup>Department of Pharmacology, Faculty of Medicine, University of Alberta, Edmonton, Canada.

**Background and aims:** Sulfonylureas can inhibit cardiac KATP channels and block ischemic preconditioning, an endogenous protective mechanism in the heart provoked by prior ischemic events. At usual therapeutic doses glyburide is more likely to inhibit cardiac KATP channels than gliclazide. Since patients with a history of ischemic heart disease (IHD) are more likely to experience ischemic preconditioning, we hypothesized these patients would be more susceptible to adverse cardiovascular effects if they are using glyburide rather than gliclazide.

**Materials and methods:** Using administrative health records from Alberta, Canada, we conducted a population-based retrospective cohort study among patients with a history of IHD using either glyburide or gliclazide as their sole sulfonylurea between 1998 and 2008. Patients were followed until reaching the primary outcome of an acute coronary syndrome (ACS) event (composite of an ACS-related hospitalization or ACS-related mortality), leaving the province or December 31, 2008. Poisson regression analyses were used to estimate the incident rate ratio (IRR) of an ACS event, accounting for time-varying exposure to glyburide or gliclazide and assuming an 80% adherence rate.

**Results:** We identified 7,166 patients using glyburide and 6,367 patients using gliclazide, of whom 2,400 (17.7%) experienced an ACS event. Glyburide and gliclazide users were similar in mean age (71.6 vs. 71.2 years) and sex (58.5% vs. 58.2% men), but glyburide users had a longer mean follow-up time (4.3 vs. 3.6 years). Compared to gliclazide use, glyburide use was associated with a significantly higher incident rate of ACS events (12.7 vs. 10.5 events/1000 person-years; IRR: 1.20, 95% confidence interval (CI) 1.08 - 1.33). After controlling for concurrent drug therapies and co-morbidities, glyburide use remained associated with a significantly greater risk of ACS event compared to gliclazide (adjusted IRR: 1.18, 95% CI 1.07 - 1.31).

**Conclusion:** Patients with type 2 diabetes and a history of IHD are more likely to experience adverse cardiovascular events if they are using glyburide rather than gliclazide. These observations support the premise that the adverse cardiovascular effects of sulfonylureas are mediated by blockade of ischemic preconditioning. Moreover, selectivity sulfonylureas for cardiac KATP channels might explain this difference in cardiovascular risk.

**The treatment of permanent neonatal diabetes secondary to Kir6.2 mutations with sulphonylureas: 5 year follow-up study**R.P. Finn, S.E. Flanagan, A.J. Chakera, A.T. Hattersley;  
Peninsula Clinical Research Facility, University of Exeter, UK.

**Introduction:** Kir6.2 mutations are identified in a third of patients with permanent neonatal diabetes, resulting in transfer to oral sulphonylureas in most cases. However, long term data on the efficacy, dosage requirement and side effect profile of their use in this population is lacking.

**Materials and methods:** We performed a retrospective follow-up study of 33 patients with permanent neonatal diabetes secondary to Kir6.2 mutations who transferred to sulphonylureas more than five years ago. Data was collected on glycaemic control, sulphonylurea dosage, neurodevelopmental features, side effects, height and weight at yearly intervals by the patients' clinicians. Data was collated and statistical analysis was performed using parametric paired T tests and non-parametric Mann-Whitney U tests

**Results:** Mean HbA1c on insulin therapy pre-transfer to sulphonylureas was 72mmol/mol (range 51 to 119). All patients had been successfully transferred to glibenclamide. HbA1c dropped to 46mmol/mol at six months following transfer to sulphonylureas. Treatment effect was sustained at five years, with a mean HbA1c of 44mmol/mol (range 34 to 56) at final five-year follow-up ( $p<0.0001$ ). Glibenclamide dose requirement reduced over time; average dose on transfer was 0.82mg/kg/day (range 0.1 to 2.02); average dose at final follow-up was 0.32mg/kg/day (range 0.06 to 0.77) ( $p<0.0001$ ). Neurodevel-

opmental features were noted to improve in seven out of the nine cases with neurodevelopmental features as part of the Developmental Delay, Epilepsy, and Neonatal Diabetes (DEND) syndrome spectrum. The two patients whose neurological features did not improve had been transferred to sulphonylureas post-puberty. Side effects such as mild hypoglycaemia and transient diarrhoea were noted in 3 cases, but were successfully managed with minor dosage adjustments. There were no adverse effects on patient growth.

**Conclusion:** This study demonstrates that sulphonylureas are effective and safe in the management of neonatal diabetes secondary to Kir6.2 mutations at 5 year follow-up. Superior glycaemic control is achieved with sulphonylureas compared to insulin treatment in this population. Treatment effect is sustained with reduced dosages of sulphonylureas required. This is in contrast to type 2 diabetes, where the early efficacy in glycaemic control achieved by sulphonylureas is not sustained at long term follow-up, and increased treatment doses are required. There is no adverse effect on paediatric growth and associated neurological features may be improved by treatment with sulphonylureas.

## 54

**Leisure time physical activity and risks of cardiovascular disease and mortality in type 2 diabetes: report from the Swedish national diabetes register**B. Zethelius<sup>1</sup>, S. Gudbjörnsdottir<sup>2</sup>, K. Eeg-Olofsson<sup>2</sup>, B. Eliasson<sup>2</sup>, J. Cederholm<sup>1</sup>;<sup>1</sup>Uppsala University, <sup>2</sup>Gothenburg University, Sweden.

**Background and aims:** Prior research has found a link between leisure time physical activity (LTPA) and cardiovascular disease (CVD) with observed preventive effects of increased LTPA. We assessed the association of level of LTPA with CVD and all cause mortality, taking risk factors for CVD into account, in patients with type 2 diabetes (T2DM) from the Swedish National Diabetes Register, NDR.

**Materials and methods:** 19,133 female (43%) and male (57%) patients aged 30-72 years, BMI  $\geq 18$  kg/m<sup>2</sup>, plasma creatinine  $\leq 150$   $\mu$ mol/l and free from CVD, congestive heart failure and atrial fibrillation at baseline (BL) in 2004-6 with follow-up until December 2009 (mean follow-up 4.8 years, 66,235 person years at risk). Five levels of LTPA were registered at BL and at end of study (EOS): never (level 1), less than 1 time weekly (level 2), 1-2 times weekly (level 3), regular 3-5 times weekly (level 4), or daily (level 5). Patients were divided into two groups: Group A (n=8,771) with lower BL-LTPA (levels 1, 2 or 3) and Group B (n=10,362) with higher BL-LTPA (levels 4 or 5) and further into two groups: Group C (n=5,675) with low BL-LTPA and low LTPA at EOS (levels 1, 2 or 3) and Group D (n=13,458) with either low BL-LTPA (levels 1, 2 or 3) or regular/higher BL-LTPA (levels 4 or 5) and with regular/higher LTPA at EOS (levels 4 or 5) taking increased LTPA into account. Hazard ratios (HR) with 95% confidence intervals (CI) were estimated using Cox regression with Group A and Group C as references, respectively, adjusting Model 1 (M1) for age, gender, diabetes duration, type of hypoglycaemic treatment, smoking and Model 2 (M2) by stratification by deciles of a propensity scores including the same covariates as M1 plus BMI, systolic blood pressure, HbA1c, LDL-cholesterol, HDL-cholesterol, triglycerides and degree of albuminuria at BL.

**Results:** HRs, CIs and p-values for: fatal and nonfatal CVD combined (n=987); fatal CVD (n=187); all cause mortality (n=656) were, respectively: for group B with A as reference;

M1: 0.83 (0.73-0.94)  $p=0.003$ ; 0.64 (0.48-0.86)  $p=0.003$ ; 0.73 (0.62-0.85)  $p<0.001$  and

M2: 0.90 (0.79-1.02)  $p=0.09$ ; 0.73 (0.54-0.98)  $p=0.03$ ; 0.78 (0.67-0.92)  $p=0.002$  and

for group D with C as reference;

M1: 0.58 (0.51-0.66)  $p<0.001$ ; 0.43 (0.32-0.58)  $p<0.001$ ; 0.50 (0.43-0.59)  $p<0.001$  and

M2: 0.62 (0.55-0.71)  $p<0.001$ ; 0.49 (0.36-0.66)  $p<0.001$ ; 0.53 (0.45-0.62),  $p<0.001$ .

**Conclusion:** Level of LTPA is related to fatal CVD and all cause mortality independent of conventional CVD risk factors in T2DM. Increased LTPA level during follow-up lowered CVD risk and mortality in this observational study on T2DM patients. Translating observational data into preventive care in individual T2DM patients has to be done with good judgement.

## OP 10 Type 2 diabetes: from risk models to survival

55

### Predictive factors of mortality among type 2 diabetic patients: do not forget clinical examination!

A. Sultan<sup>1</sup>, J. Daures<sup>2</sup>, C. Piot<sup>3</sup>, D. Mariano-Goulart<sup>4</sup>, A. Avignon<sup>1</sup>;  
<sup>1</sup>Nutrition-Diabetology, CHU Lapeyronie, <sup>2</sup>Biostatistic, IURC, <sup>3</sup>Cardiology, CHU Arnaud de Villeneuve, <sup>4</sup>Nuclear Medicine, CHU Lapeyronie, Montpellier, France.

**Background and aims:** The incidence of diabetes mellitus has increased at an alarming rate over the past 2 decades. The association between diabetes and cardiovascular diseases is well established, as still the main cause of death among these patients. We followed a cohort of 703 high risk type 2 diabetic patients during a median follow up of 5,8 years and thought to determine predictive factors associated with global mortality and cardiovascular mortality.

**Materials and methods:** Survival analysis was made. For univariate analysis, we used Kaplan Meyer methods. Covariables with p-value.

**Results:** Among these patients, 58% were male, mean age of 62,06 years, with a mean length of diabetes of 13,80 years and a HbA1c of 8,35%. 29% had positive microalbuminuria or proteinuria, 14% had a creatinin clearance inferior to 60 ml/min. 12% had obliterating arteriopathy of the lower limbs defined by pulse abolition noticed by 2 differents physicians. Among cardiovascular risk factors, mean LDL was 1,10 g/l, mean HDL was 0,53 g/l and 54% of these patients were under statin treatment. 60% were classified as having hypertension, and 43% were currents smokers. During follow up, 67 patients died (9,5%) with mainly cardiovascular death (57 patients). In multivariate analysis, obliterating arteriopathy of the lower limbs, insulin treatment, antiagregant treatment use, triglyceride level above 1,5 g/l were associated with global mortality. Obliterating arteriopathy of the lower limbs was the strongest predictor of mortality (RR=2,68; IC95%:1,58-4,52). Regarding predictive factors associated with cardiovascular mortality, we found that obliterating arteriopathy of the lower limbs, creatinin clearance under 60ml/min and high systolic blood pressure were associated. Once again, obliterating arteriopathy of the lower limbs was the strongest predictor of cardiovascular mortality (RR=2,79; IC95%:1,68-4,64).

**Conclusion:** In conclusion, presence of obliterating arteriopathy of the lower limbs diagnosed by clinical examination was the strongest factor associated with global and cardiovascular mortality in high risk type 2 diabetic patients. This should lead us to intensify risk factors treatment in this group of patients and maybe to carefully discuss coronarography exploration.

56

### Comparison of predictability of cardiovascular estimation risk models in Greek diabetic patients

N. Melas, A. Kamaratos, K. Mpotsios, M. Sevdalis, K. Tzirogiannis, C. Verras, G. Panoutsopoulos, P. Gavra, A. Melidonis;  
 Diabetes Center, Tzanio General Hospital, Piraeus, Greece.

**Background and aims:** Objective of this prospective study is the comparison of the predictability of two established cardiovascular estimation risk engines, UKPDS (UK Prospective Diabetes Study) Risk Engine and HeartScore (Systematic Coronary Risk Evaluation), in diabetic patients.

**Materials and methods:** This prospective study was conducted in the Diabetes Center of Tzanio General Hospital in the period 1998 - 2001. The study population included a thousand eighty four (n=1084) diabetic patients. They have been observed for ten years regarding two cardiovascular end points, fatal coronary heart disease (CHD) and fatal stroke. The initial data was inputted individually on both of the risk engines, generating rates of estimation of cardiovascular risk. These rates were compared with the real outcome data after 10 years follow up of these patients. ROC curves was used in order to identify the predictability of the two models, comparing the estimated outcomes calculated in the onset of the study and the real outcomes recorded on the conclusion of the study after 10 years follow up.

**Results:** The study sample included 1084 diabetic patients (498 M / 586 F) with mean age of 60 years for both of the sex groups and mean diabetes duration of 6.9 years for the males and 8.2 years for the females. The comparison of the predictability of the two risk engines was completed for the totality of

the sample and by the gender individually. For the total of the study sample, the mean value ( $\pm$  SD) of the estimated risk of fatal event (CHD and stroke) was  $17.95 \pm 0.48$  for the UKPDS and  $5.91 \pm 0.14$  for the HeartScore risk engine. The real outcome was 130 total fatal events (68 CHD and 52 Stroke). Using the ROC curves we observed that in UKPDS the area under the curve (AUC) was 0.831 (95% CI, 0.794 - 0.867,  $p < 0.001$ ) while in HeartScore was 0.782 (95% CI, 0.747 - 0.818,  $p < 0.001$ ). Comparing the risk engines by gender individually we observed that the mean value of the estimated risk of fatal event in women group was  $13.84 \pm 0.52$  for the UKPDS and  $4.15 \pm 0.12$  for the HeartScore risk engine. The real outcome in this group was 42 fatal events (20 CHD and 22 Stroke). In the same group in UKPDS the AUC was 0.794 (95% CI, 0.735 - 0.852,  $p < 0.001$ ) while in HeartScore was 0.783 (95% CI, 0.735 - 0.832,  $p < 0.001$ ). In men group, the real outcome was 78 fatal events (48 CHD and 30 Stroke) while the mean value of the estimated risk of fatal event was  $22.81 \pm 0.78$  for the UKPDS and  $8.00 \pm 0.23$  for the HeartScore risk engine. In men group we observed that in UKPDS the AUC was 0.841 (95% CI, 0.796 - 0.887,  $p < 0.001$ ) while in HeartScore was 0.747 (95% CI, 0.694 - 0.799,  $p < 0.001$ ).

**Conclusion:** Comparing two established cardiovascular estimation risk engines in a large sample of diabetic patients after 10 years follow up, we observed that the prediction ability of fatal cardiovascular event (CHD and stroke) of UKPDS overmatches against HeartScore. We observed furthermore that the predictability of UKPDS overmatches against HeartScore in both genders individually, especially in men.

57

### Incidence of death, hospitalisation and new left ventricular dysfunction in type 2 diabetic patients. Two years follow-up in the DYDA study

C.B. Giorda<sup>1</sup>, E. Nada<sup>1</sup>, G. Vespasiani<sup>2</sup>, L. Bortolato<sup>3</sup>, D. Lucci<sup>4</sup>, A. Leopardi<sup>5</sup>, E. Zarra<sup>6</sup>, G. De Simone<sup>7</sup>, M. Comaschi<sup>8</sup>, on behalf of DYDA Investigators;  
<sup>1</sup>Diabetology Dept., Ospedale Maggiore, Chieri, <sup>2</sup>Diabetology Dept., Ospedale Madonna del Soccorso, San Benedetto del Tronto, <sup>3</sup>Medicine Dept., Ospedale Civile, Mirano, <sup>4</sup>Centro Studi ANMCO, Firenze, <sup>5</sup>Diabetology Dept., Ospedale S. Giovanni di Dio, Firenze, <sup>6</sup>Diabetology Dept., Spedali Civili, Brescia, <sup>7</sup>Clin Experiment Medicine Dept., AOU Federico II, Napoli, <sup>8</sup>Centro per il Piede Diabetico, ICLAS, Rapallo, Italy.

**Background and aims:** T2DM is cause of CV complications, atherosclerosis, heart failure and death. DYDA is a prospective, multicenter epidemiological study in 960 T2DM patients, aged >45 years and without overt cardiac diseases. Baseline echocardiographic examination revealed a high prevalence of preclinical LV systolic (21%) and diastolic dysfunction (27%) or both (12%) (LVD), measured by midwall shortening (MFS) and transmitral flow pattern, respectively, as previously reported. Patients were followed-up for 2 years. In the present study, we report data on echocardiographic re-evaluation and clinical events.

**Materials and methods:** Systolic LVD (DLVD) was defined as EF  $\leq 50\%$  or MFS  $\leq 15\%$ ; diastolic LVD (SLVD) was identified in all conditions different from "normal", defined as transmitral E/A ratio between 0.75 and 1.5 and E velocity deceleration time >140 msec. The primary outcome was a composite of major events, (all-cause death and hospital admissions). Secondary endpoint was the incidence of new LVD.

**Results:** Follow-up data were available on 957 patients. During the follow-up 15 deaths (1.6%, 3 CV death, 11 non CV death, 1 of unknown etiology) and 181 hospital admissions were observed in 139 patients (48 for CV cause, 133 for non CV cause). In multivariate analysis, older age (67 vs 56 yrs OR 1.41, 95% CI 1.05-1.88), high LDL (134 vs 93 mg/dL OR 1.39, CI 1.08-1.78), low HDL (57 vs 42.5 mg/dL OR 0.76, CI 0.60-0.98), high Hb1Ac (7.6 vs 6.0% OR 1.3, CI 1.05-1.62), peripheral arterial disease (OR 3.49, CI 1.54-7.9) and treatment with repaglinide (OR 2.01, CI 1.17-3.46) were independently associated with a major event. LVD was observed at baseline or during follow-up in 88.1% (616/699) of patients; a systolic LVD in 63.9% (338/529), and a diastolic LVD in 66.5% (463/696). In a multivariate analysis, older age (67 vs 56 yrs OR 2.45, 95% CI:1.86-3.23), high Hb1Ac (7.6 vs 6.0% OR 1.25, 95% CI:1.01-1.54), high heart rate (80 vs 68 bpm OR 1.23, 95% CI: 1.03-1.47) and high DBP (90 vs 78 mmHg OR 2.29; 95% CI: 1.41-3.72) were independently associated with DLVD; whereas SLVD was associated only with waist circumference (106 vs 92 cm OR 1.39, 95% CI:1.05-1.84). New onset of systolic LVD (either EF  $< 50\%$  or MFS  $< 15\%$ ) was observed in 66/388 pts. (17.0%) and that of diastolic LVD in 126/572 pts (22.0%).

**Conclusion:** In patients with DM without overt cardiac disease at baseline, LVD is a frequent finding, and is associated with older age, higher HbA1c, heart rate, diastolic BP and waist. In these patients, all-cause death or hospi-

talisation occurred in nearly 16% of the cases at mid-term follow-up, being the great majority of them of non-CV reason. Independent predictors of such adverse clinical events were older age, pathologic lipid profile, poor control of DM, peripheral arteriopathy and repaglinide therapy.

### Have insulin-treated diabetic patients, admitted with non-ST elevation segment acute coronary syndrome, a worst prognosis than those treated with an oral anti-diabetic?

J. Chin, P. Sousa, N. Marques, J. Silva, J. Amado, W. Santos, J. Mimoso, A. Lopes, E. Pina, A. Camacho, V. Brandão, I. Jesus;  
Hospital of Faro, Portugal.

**Background and aims:** There are questions about what is the best therapeutic strategy for patients (P) with diabetes mellitus (DM) who suffered a non-ST segment elevation acute coronary syndrome (NSTACS). The main question is on the benefits of use of insulin versus oral anti-diabetic for glycemic control in these P. The aim of this study was to determine if DM insulin-treated (IT) P admitted with NSTACS have a higher complications and mortality rates during hospitalization and after discharge, than those treated with oral anti-diabetics (OAD).

**Materials and methods:** We conducted a retrospective, descriptive and correlational study, based on a prospective registry, involving P admitted with NSTACS in a Cardiology Department between January/2006 to October/2010. We evaluated baseline characteristics, admission data, therapeutic strategy and a univariate and multivariate analyzes for hospital events - ventricular fibrillation (VF), complete atrioventricular block (BAVC), re-AMI (RE-MI), major bleeding (MB), stroke and in-hospital mortality - and after discharge - RE-MI, stroke, readmission for heart disease (RHD) and mortality (cardiovascular and overall). Statistical analysis was performed using SPSS 13.0.

**Results:** Of the 1086 P admitted for NSTACS, 357 P were diabetic and of these 50 P (14%) were on insulin therapy. The DM IT P had more frequently a history of peripheral arterial disease (PAD), (30% vs 12.1%,  $p=0.001$ ), coronary artery bypass graft (CABG) (24% vs 12.4%,  $p=0.028$ ) and left ventricular dysfunction at admission (42.9% vs 25.4%,  $p=0.011$ ). There were no significant differences in other baseline characteristics, admission data or therapeutic strategy. Regarding the in-hospital complications, there were no statistically significant differences between the two groups, even in the mortality (0% vs 0.7%,  $p=0.567$ ). The mean follow-up (FU) was  $41 \pm 16$  months (FU rate of 92%). The DM IT P had the similar complications events than OAD DM P - RE-MI (22.5% vs 20.6%,  $p=0.788$ ), stroke (2.5% vs 3.2%) and RHD (25% vs 30.6%,  $p=0.475$ ). They also presented a similar CVM (11.4% vs 8.8%,  $p=0.589$ ) and OM (27.3% vs 22.3%,  $p=0.462$ ).

**Conclusion:** 1. The diabetic patients insulin-treated admitted with NSTACS presented more frequently a history of PAD, CABG and left ventricle dysfunction, than those treated with oral anti-diabetics. 2. Prognosis during hospitalization and after discharge were similar for both groups.

## 59

### Diabetes mellitus in patients with non-ST segment elevation acute coronary syndrome - worse prognosis?

P. Sousa, N. Marques, J. Chin, J. Silva, J. Amado, W. Santos, A. Lopes, E. Pina, J. Mimoso, S. Pereira, V. Brandão, I. Jesus;  
Hospital of Faro, Portugal.

**Background and aims:** The aim of this study was to determine if diabetes mellitus (DM) patients (P) admitted in a Cardiology Department (CD) with non-ST segment elevation acute coronary syndrome (NSTACS) have higher rates of complications and mortality, during hospitalization and after discharge, compared with nondiabetics P. We also sought to determine the predictors of mortality in DM P with NSTACS.

**Materials and methods:** We conducted a retrospective, descriptive and correlational study, based on a prospective registry, involving P admitted with NSTACS between January 2006 to October 2010. We evaluated baseline characteristics, admission data, in-hospital events - ventricular fibrillation, complete atrioventricular block, re-infarction (RE-MI), major bleeding, stroke, mortality and follow-up (FU) events - RE-MI, stroke, readmission for heart disease (RHD) and mortality (cardiovascular - CVM and overall - OM)). Midterm monitoring was conducted by a cardiologist ( $41 \pm 16$  months, FU

rate 93%). We also performed an univariate and multivariate analysis, in DM P, of in-hospital mortality and mortality (CVM and OM) during FU. Statistical analysis was performed using SPSS 13.0.

**Results:** Of the 1086 P admitted with NSTACS, 357 (33%) had DM, of which 50 P (14%) were under insulin therapy. The DM P were mostly women ( $p=0.016$ ), hypertensive ( $p<0.001$ ), had dyslipidemia ( $p<0.001$ ), and were non-smokers ( $p<0.001$ ). More often had a history of stroke ( $p=0.005$ ), angina ( $p<0.001$ ), myocardial infarction ( $p<0.001$ ) and peripheral arterial disease (PAD) ( $p<0.001$ ). During hospitalization, there were no significant difference between the two groups concerning the complications and the mortality rates. The in-hospital mortality rate of the DM P was 0.6%. There were no independent predictors of mortality. During the FU, DM P presented more RE-MI (20.9% vs 8.7%,  $p<0.001$ ) and more RHD (29.8% vs 20.9%,  $p=0.004$ ). DM P had similar CVM (9.2% vs 7.1%,  $p=0.253$ ) but a higher OM (22.9% vs 16.2%,  $p=0.011$ ). In the DM P, the independent predictors of CVM were the female gender ( $p=0.011$ ), previous myocardial infarction ( $p=0.010$ ) and not performing percutaneous coronary intervention (PCI) ( $p=0.027$ ). The independent predictors of OM were a history of PAD ( $p=0.042$ ) and the left ventricle ejection fraction  $<30\%$  ( $p<0.001$ ).

**Conclusion:** 1. DM P had more cardiovascular risk factors for coronary disease. 2. During hospitalization, despite the higher risk associated to DM P, there were no differences regarding complications and mortality rates between the two groups. 3. There were no independent in-hospital mortality predictors, probably due a low mortality rate of the DM P. 4. After discharge, DM P had a higher risk of RE-MI and RHD, with a higher OM, at the expense on non-CVM. 5. In the DM P, the independent CVM predictors were female gender, previous myocardial infarction and not performing PCI. The independent predictors of OM were a history of PAD and left ventricle dysfunction.

### High 3-year-mortality rates in females with newly diagnosed diabetes after acute STEMI and NSTEMI: results of the SWEETHEART registry

D. Tschöpe<sup>1,2</sup>, F. Towae<sup>3</sup>, A. Papp<sup>4</sup>, E. Deeg<sup>5</sup>, J. Senges<sup>5</sup>, U. Zeymer<sup>3</sup>, R. Zahn<sup>3</sup>, P. Bramlage<sup>6</sup>, A.K. Gitt<sup>3,5</sup>;

<sup>1</sup>Stiftung „Der herzkrankte Diabetiker“, Stiftung in der Deutschen Diabetes-Stiftung, Bad Oeynhausen, <sup>2</sup>Universitätsklinik der Ruhr-Universität Bochum, Herz- und Diabeteszentrum, Bad Oeynhausen, <sup>3</sup>Medizinische Klinik B - Abteilung für Kardiologie, Klinikum der Stadt Ludwigshafen GmbH, <sup>4</sup>Med. Klinik B, Kardiologie, Herzzentrum Ludwigshafen, <sup>5</sup>Institut für Herzinfarktforschung Ludwigshafen an der Universität Heidelberg, Ludwigshafen, <sup>6</sup>Institut für Pharmakologie und präventive Medizin, Mahlow, Germany.

**Background and aims:** There is a considerable co-morbidity between coronary artery disease (CAD) and diabetes. Dysglycaemia is however frequently unknown and guidelines released by the ESC / EASD now recommend testing for diabetes using an oral glucose tolerance test (OGTT) in patients with established CAD.

**Materials and methods:** A total of 2,767 consecutive patients presenting with STEMI or NSTEMI were enrolled into SWEETHEART starting in 2007. Except for those with known diabetes all patients underwent an OGTT at day 4 after admission. The present analysis reports the prevalence of dysglycaemia according to gender and the impact of newly diagnosed diabetes on mortality at the 3-year follow-up.

**Results:** Female patients were older but had less prior myocardial infarction (MI) and percutaneous coronary interventions (PCI) than male patients. Known diabetes was more frequent (30.2 vs. 23.1%) and diabetes duration longer (10 vs. 7 years) in female patients as was the rate of newly diagnosed diabetes upon OGTT (19.7 vs. 15.3%). In contrast to men, 3-year mortality rates with established and newly diagnosed diabetes was virtually identical (30.0 and 30.5% respectively) in women (35.4 vs. 21.8% in men).

**Conclusion:** Female patients have substantially higher rates of known as well as newly diagnosed diabetes compared to their male counterparts when presenting with acute myocardial infarction. Mortality rates with newly diagnosed diabetes are substantially higher in female than in male patients at the 3 year follow-up.

	Female (n=706)	Male (n=2061)	p-value

## OP 11 Links between obesity, inflammation and insulin resistance

### 61

#### N-(Carboxymethyl)lysine-RAGE axis: a novel link between obesity, inflammation and insulin resistance

K. Gaens<sup>1</sup>, P.M.G. Niessen<sup>1</sup>, M.M.J. van Greevenbroek<sup>1</sup>, C.J.H. van der Kallen<sup>1</sup>, H.W.M. Niessen<sup>2</sup>, S.S. Rensen<sup>1</sup>, W.A. Buurman<sup>1</sup>, J.M. Greve<sup>1</sup>, G.H. Goossens<sup>1</sup>, E.E. Blaak<sup>1</sup>, M.A.M. van Zandvoort<sup>1</sup>, A. Bierhaus<sup>3</sup>, C.D.A. Stehouwer<sup>1</sup>, C.G. Schalkwijk<sup>1</sup>

<sup>1</sup>Maastricht University Medical Center, Netherlands, <sup>2</sup>Vrije Universiteit Medical Center, Amsterdam, Netherlands, <sup>3</sup>University of Heidelberg, Germany.

**Background:** Obesity is characterized by a dysregulated production and secretion of pro- and anti-inflammatory adipokines, which are critically involved in the pathogenesis of obesity-related complications such as insulin resistance and type 2 diabetes mellitus. However, the mechanisms underlying an abnormal expression of adipokines have not been fully elucidated. We hypothesized that accumulation of the advanced lipoxidation endproduct, N<sup>ε</sup>-Carboxymethyllysine (CML) in adipose tissue in obesity causes dysregulation of adipokines, thus contributing to the development of obesity-related insulin resistance.

**Methods:** Accumulation of CML in obese adipose tissue was assessed by immunohistochemistry. Plasma levels of CML were measured by UPLC-Tandem MS in controls (n=77), patients with familial combined hyperlipidemia (FCHL, n=42), and obese subjects (n=44). To study trapping of circulating CML in adipose tissue and to address the role of CML-RAGE axis in the dysregulation of inflammatory cytokines, receptor for advanced glycation endproduct (RAGE)-deficient obese mice (RAGE<sup>-/-</sup>/Lepr<sup>Db/-</sup> mice) were generated by crossing RAGE<sup>-/-</sup> with Lepr<sup>Db/-</sup> mice. The effect of CML on expression of inflammatory markers was also studied in human adipocyte cell culture. Finally, the role of CML-RAGE axis in the development of insulin resistance was investigated by performing glucose and insulin tolerance tests in RAGE<sup>-/-</sup>/Lepr<sup>Db/-</sup> and RAGE<sup>+/+</sup>/Lepr<sup>Db/-</sup> mice.

**Results:** We report a strong CML accumulation in adipose tissue in obesity, with significantly more accumulation in visceral than in subcutaneous adipose tissue (1.5±0.2 vs 1.3±0.2, p<0.001). Circulating CML levels were lower in obese subjects compared with controls (1.3±0.2μM vs 1.9±0.5μM, p<0.001), and were inversely related to visceral adipose tissue mass (r=-0.557, p<0.001), suggesting trapping of circulating CML in adipose tissue. Fluorescently labeled CML was trapped in adipocytes of obese Lepr<sup>Db/-</sup> mice, but not in RAGE<sup>-/-</sup>/Lepr<sup>Db/-</sup> mice. Moreover, inhibition of CML trapping in RAGE<sup>-/-</sup>/Lepr<sup>Db/-</sup> was associated with less inflammation (decreased pro-inflammatory cytokines IL-1β, IL-12, IL-6, IL-8, TNF-α, IFN-γ, and increased anti-inflammatory cytokines IL-10 and adiponectin). This demonstrates that RAGE is a key modulator of CML trapping and that CML-RAGE axis plays a major role in inducing inflammatory responses in obesity. Incubation of human adipocytes with CML also resulted in upregulation of pro-inflammatory markers, whereas anti-inflammatory markers decreased. Furthermore, we demonstrated that intervening with CML trapping and CML-RAGE mediated inflammatory responses were associated with improved glucose homeostasis in RAGE<sup>-/-</sup>/Lepr<sup>Db/-</sup> mice.

**Conclusion:** Our findings demonstrate the occurrence of RAGE-dependent CML trapping in adipose tissue in obesity, which contributes to the dysregulation of adipokines and development of obesity-related insulin resistance. Targeting this novel mechanism of altered production of adipokines may have therapeutic potential in the management of the obesity-associated complications.

## 62

**Inhibition of PSGL-1 ameliorates obesity-related insulin resistance by prevention of inflammation in adipose tissue and liver in db/db mice**D. Hirota<sup>1,2</sup>, K. Shikata<sup>1,3</sup>, C. Sato<sup>1</sup>, R. Kodera<sup>1,3</sup>, S. Miyamoto<sup>1</sup>, N. Kajitani<sup>1</sup>, T. Takatsuka<sup>1</sup>, D. Ogawa<sup>1</sup>, H. Kataoka<sup>1</sup>, H. Makino<sup>1</sup>;<sup>1</sup>Department of Medicine and Clinical Science, Okayama University Graduate School of Medicine Dentistry and Pharmaceutical Sciences,<sup>2</sup>Diabetes Center, Okayama University Hospital, <sup>3</sup>Center for Innovative Clinical Medicine, Okayama University Hospital, Japan.

**Background and aims:** There have been accumulating evidences that inflammation in adipose tissue is involved in the mechanism of obesity-related insulin resistance. Macrophages and proinflammatory cytokines are increased in visceral adipose tissues of obese people and animal models. Infiltration of monocyte/macrophage is mediated by the interaction of cell adhesion molecules expressed on monocytes and endothelial cells. We previously screened the gene expression profiles in adipose tissues from obese mice using DNA microarray and found that P-selectin glycoprotein ligand-1 (PSGL-1) is up-regulated in both db/db mice and high-fat diet (HFD) fed mice. PSGL-1 is expressed on both leukocytes and endothelial cells and binds to P-, L- and E-selectin. We found PSGL-1 is expressed on both endothelial cells and macrophages in adipose tissues of obese mice. Furthermore, we demonstrated that PSGL-1 deficient mice fed with HFD revealed decreased macrophage infiltration into adipose tissues, improved adipocyte hypertrophy and insulin resistance as compared with wild type mice fed with HFD. The aim of this study is to clarify the effects of anti-PSGL-1 antibody on the adipose tissue and the liver in obese db/db mice.

**Materials and methods:** Anti-PSGL-1 monoclonal antibody or normal rat IgG was administered by intraperitoneal injection to six week-old male db/db mice. An intraperitoneal insulin tolerance test (ipITT) and an intraperitoneal glucose tolerance test (ipGTT) were performed at 7 weeks old. We measured serum lipids, insulin, HbA1c and adipocytokines. We also examined the gene expression of proinflammatory cytokines, chemokines, adhesion molecules, adipocytokines and infiltration of macrophages in epididymal white adipose tissues (WAT) and liver.

**Results:** There was no significant difference in body weight, weight of epididymal WAT and liver, total cholesterol, free fatty acid and HbA1c. Significant reductions were observed in fasting blood glucose and LDL cholesterol in treated group (treated group vs control group,  $p < 0.05$ ). The average values of triglyceride and fasting IRI were decreased in treated group as compared with control group. The size of adipocytes in epididymal WAT was also significantly decreased in treated group as compared with control group. Glucose tolerance and insulin sensitivity were significantly improved in treated group in ipITT and in ipGTT. The expressions of MCP-1, CD68 (treated group vs control group,  $p < 0.05$ ) and IP-10 (treated group vs control group,  $p < 0.01$ ) were decreased in the adipose tissue and the liver in treated group as compared with control group.

**Conclusion:** The administration with anti-PSGL-1 antibody revealed decreased macrophage infiltration not only in the adipose tissues but also in the liver in db/db mice. Anti-PSGL-1 antibody improved adipocyte hypertrophy and insulin resistance. These results provide the direct evidence that PSGL-1-selectin pathway promotes the recruitment of macrophages into the adipose tissue and the liver. PSGL-1 might be a novel target for the prevention of insulin resistance in obesity.

**The functional role of oncostatin M in the development of insulin resistance in mice**Y. Morikawa<sup>1</sup>, T. Komori<sup>1</sup>, M. Tanaka<sup>2</sup>, E. Senba<sup>1</sup>, A. Miyajima<sup>2</sup>;<sup>1</sup>Anatomy and Neurobiology, Wakayama Medical University, Wakayama,<sup>2</sup>Laboratory of Cell Growth and Differentiation, Institute of Molecular and Cellular Bioscience, The University of Tokyo, Japan.

**Background and aims:** Oncostatin M (OSM) is a member of the interleukin (IL)-6 family of cytokines and plays important roles in the variety of biological functions including the regulation of hematopoiesis, liver development, and inflammatory response. However, the relationship between OSM and metabolic disease remains unclear. In the present study, we investigated the roles of OSM in the adipose tissue inflammation and insulin resistance.

**Materials and methods:** We used OSMR $\beta$ -deficient (OSMR $\beta$ <sup>-/-</sup>) mice to examine the role of OSM in the development of insulin resistance. We also investigated the therapeutic effect of OSM on insulin resistance of ob/ob mice.

**Results:** OSMR $\beta$  was mainly localized in the adipose tissue macrophages (ATMs) of obese mice suggesting that OSM contributes to the development of adipose tissue inflammation by regulating the functions of ATMs. To test this possibility, we first analyzed adipose tissue inflammation and insulin resistance in OSMR $\beta$ <sup>-/-</sup> mice on a normal diet (ND). OSMR $\beta$ <sup>-/-</sup> mice showed insulin resistance, whereas there were no significant differences in the body weights between OSMR $\beta$ <sup>+/+</sup> and OSMR $\beta$ <sup>-/-</sup> mice. In ATMs of OSMR $\beta$ <sup>-/-</sup> mice, the ratio of M1/M2 macrophages was increased compared to that in OSMR $\beta$ <sup>+/+</sup> mice. In addition, the expression of TNF- $\alpha$  was increased, while the expression of IL-10 was decreased in the adipose tissue of OSMR $\beta$ <sup>-/-</sup> mice. Next, we analyzed adipose tissue inflammation and insulin resistance in OSMR $\beta$ <sup>-/-</sup> mice on a high fat diet (HFD). OSMR $\beta$ <sup>-/-</sup> mice fed a HFD exhibited higher insulin resistance than that in OSMR $\beta$ <sup>+/+</sup> mice. The increased expression of TNF- $\alpha$  and IL-10 was observed in OSMR $\beta$ <sup>-/-</sup> mice fed a HFD. To determine the direct effects of OSM on macrophages, we treated OSM to mouse peritoneal exudate macrophages (PEMs). The expression of IL-10 was increased by OSM in PEMs in addition to the activation of signal transducer and activator of transcription 3 and cAMP response element binding protein. In addition, the expression of M2 markers (arginase-1 and CD206) was increased in OSM-treated PEMs compared to those in vehicle-treated PEMs. These results indicate that OSM contributes to the development of insulin resistance by polarizing the phenotypes of macrophages to M2 with the induction of IL-10 expression. Finally, OSM was intraperitoneally injected into ob/ob mice to assess the effects of OSM on the insulin resistance of obese mice. Glucose intolerance and insulin resistance in ob/ob mice was improved by OSM. In addition, the expression of a marker of M1 macrophage (iNOS) and pro-inflammatory cytokine (TNF- $\alpha$ ) were decreased, while the expression of markers of M2 macrophage (CD206 and CD163) and anti-inflammatory cytokine (IL-10) were increased in the adipose tissue of OSM-injected ob/ob mice. These results suggest that OSM improves adipose tissue inflammation and insulin resistance during obesity.

**Conclusion:** OSM may play important roles in the development of adipose tissue inflammation and insulin resistance by changing the phenotypes of macrophages to M2 and inducing the expression of IL-10 directly.

## 64

**Interleukin 21 knockout protects from adipose tissue inflammation in a diet-induced obesity model**

M. Fabrizio, A. Marino, V. Casagrande, V. Marchetti, M. Mavilio, M. Cavallera, R. Menghini, F. Pallone, R. Lauro, G. Monteleone, M. Federici; Medical School, University of Rome Tor Vergata, Italy.

**Background and aims:** Interleukin-21, a pro-inflammatory cytokine, is mainly produced by multiple effector lymphocyte CD4<sup>+</sup> T and Natural Killer T cells. IL-21 receptors are widely expressed resulting to pleiotropic actions of IL-21 on multiple tissues. Recent studies suggested a role for IL-21 in mediating chronic inflammation. Obesity is accompanied by adipose tissue chronic low-grade inflammation, which promotes insulin resistance and type-2 diabetes. In particular regulatory T cells (Tregs) may play a critical role in modulating adipose tissue inflammation via interactions with both adaptive and innate immune system. Interestingly Tregs are highly enriched in the abdominal fat of lean mice but are specifically reduced in adipose tissue of obese animals. Because IL-21 is known to exert negative effects on Treg activity we hypothesized that it could play a role in obesity-induced insulin resistance.

**Materials and methods:** We compared C57BL/6J WT and IL-21 knockout (IL-21KO) mice in a context of diet induced obesity (DIO). Animals were subjected to metabolic characterization: weight and blood glucose monitoring, glucose and insulin tolerance tests, energy expenditure and activity rating. At the end of 20 weeks of DIO, WT and KO mice were sacrificed and metabolically active organs were collected for molecular and histological studies. Fasting and feeding sera were collected for assessment of the amount of insulin and NEFA.

**Results:** Adipocytes, stromal vascular cells and hepatocytes isolated from DIO wt mice showed increased levels of IL-21 mRNA compared to mice under standard chow diet, suggesting its involvement in developing or in maintaining the inflammatory condition associated to obesity. During DIO, IL-21 KO mice compared to wt littermates showed lower weight, characterized by reduced adiposity associated with decreased fat pad mass and adipocyte size ( $P < 0.0001$ ), lower levels of blood glucose ( $p < 0.005$ ) and hypoinsulinemia

( $p < 0.05$ ). Metabolic differences were observed mostly in the fasting state suggesting an involvement of IL-21 in adaptation to fasting. WAT (white adipose tissue) of IL-21 KO mice showed higher levels of IRF4 ( $P < 0.005$ ) and its targets *Penpla2* and *Lipe*, compared to WAT of wt; this was related to an increase in the amount of serum NEFA. Despite fasting hypoglycemia, Real Time-PCR experiments revealed increased levels of PEPCK, G6pase ( $p < 0.05$ ) and FoxO1 in IL-21 KO livers, compared to wt littermates livers. Western blot analysis showed reduced phosphorylation and acetylation of FoxO1 ( $p < 0.05$ ). RNA levels of inflammatory genes as F4/80 and CD68 were reduced in liver and WAT of IL-21 KO mice ( $p < 0.05$ ) compared to wt; this suggests a low infiltration of proinflammatory macrophages M1 in adipose tissue of IL21 KO mice. On the contrary, we found increased RNA expression of YM1 and Mgl2 ( $P < 0.05$ ) suggesting a high presence of alternatively activated macrophages M2.

**Conclusion:** Taken together, our data indicate that IL-21 KO mice are partially protected from the metabolic injury caused by HFD. Since IL21 KO mice fed a HFD showed tendency to hypoglycemia and increased lipolysis, further studies are needed to elucidate whether these effects are dependent from modulation on adipose tissue inflammation or are directly related to modulation of insulin sensitivity in both adipose and hepatic cells.

## 65

### Intestinal microbiota translocation is associated with inflamed visceral adipose tissue

M. Nieuwdorp<sup>1,2</sup>, A. Vrieze<sup>1</sup>, L. Jonker<sup>1</sup>, P. Surendran<sup>2</sup>, N. de Sonnaville<sup>1</sup>, G.M. Dallinga-Thie<sup>2</sup>, R.S. Kootte<sup>2</sup>, H.G.G. Heilig<sup>3</sup>, E.G. Zoetendal<sup>3</sup>, O.R.C. Busch<sup>4</sup>, S. van der Meij<sup>3</sup>, B. van Wagenveld<sup>6</sup>, W.M. de Vos<sup>3,7</sup>, F. Holleman<sup>1</sup>, J. Hoekstra<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, Academic Medical Center, Amsterdam, Netherlands, <sup>2</sup>Department of Vascular Medicine, Academic Medical Center, Amsterdam, Netherlands, <sup>3</sup>Laboratory of Microbiology, Wageningen University, Netherlands, <sup>4</sup>Department of Surgery, Academic Medical Center, Amsterdam, Netherlands, <sup>5</sup>Department of Surgery, Flevo ziekenhuis, Almere, Netherlands, <sup>6</sup>Department of Surgery, Sint Lucas Andreas Ziekenhuis, Amsterdam, Netherlands, <sup>7</sup>Department of Basic Veterinary Medicine, University of Helsinki, Finland.

**Background and aims:** Inflammation of visceral fat is a key regulator in the development of insulin resistance and subsequent type 2 diabetes, yet the pathophysiological trigger for this chronic inflammation remains poorly understood. As the intestinal microbiota plays a pivotal role in metabolism, we hypothesized that altered faecal intestinal microbiota composition induces endotoxemia and subsequent visceral adipose tissue inflammation. Thus, the aim of our study was to investigate whether a) faecal intestinal microbiota differs between humans with and without inflamed adipose tissue and b) whether intestinal microbial DNA can be detected in adipose tissue.

**Material and methods:** Treatment naïve healthy men and women (Mean BMI 29.0 kg/m<sup>2</sup>), scheduled for elective laparoscopic cholecystectomy were included. Fasting metabolic markers and inflammation parameters (hsCRP and lipopolysaccharide-binding protein, LBP) were measured. At the day of surgery, patients collected stool samples for the deep and global phylogenetic profiling of the intestinal microbiota using the Human Intestinal Tract Chip (HITChip). During surgery visceral adipose tissue was obtained in sterile endotoxin free containers and immediately processed for macrophage (CD68) staining using immunohistochemistry and bacterial DNA detection.

**Results:** Based on plasma LBP we divided the patients into two groups: high ( $n=12$ ) vs. low LBP ( $n=12$ ) plasma levels. CD68 staining in the visceral adipose tissue showed LBP was positively associated with the accumulation of macrophages. Even though the number of adipocytes were similar between low and high LBP, CD68 staining revealed 48% higher number of macrophages in high LBP compared to the low LBP (8.5:4.1 per um of adipose tissue respectively,  $p < 0.0001$ ). In addition, the total group also showed significant correlation between plasma LBP and the amount of CLS, Spearman's  $\rho=0.4$ ,  $p < 0.05$ ). Finally, we demonstrated the presence of bacterial DNA in this visceral adipose tissue.

**Conclusion:** We show that plasma LBP is associated with macrophage accumulation in visceral fat tissue of otherwise healthy obese subjects. Since bacterial DNA was present in these visceral fat specimens, our data imply that intestinal microbiota may play an initiating role in chronic inflammation of visceral fat. Comparative analysis of the intestinal microbiota composition and diversity will be presented and discussed.

### Toll like receptor 3 initiates adipose tissue inflammation during obesity

J.A. van Diepen, E.J.P. van Asseldonk, D.B. Ballak, R. Stienstra, T.B. Koenen, H.J. Jansen, M.G. Netea, C.J. Tack; General Internal Medicine, UMC St Radboud Nijmegen, Netherlands.

**Background and aims:** Obesity is accompanied by a chronic low-grade inflammation that contributes to the development of insulin resistance and type 2 diabetes. In adipose tissue, obesity induces infiltration of macrophages and secretion of pro-inflammatory cytokines such as IL-1 $\beta$ , IL-6 and TNF $\alpha$ . Toll like receptors (TLRs) are the frontline of innate immunity and can sense specific exogenous and endogenous ligands. Both TLR2 and TLR4 have shown to play a role the development of obesity-associated adipose tissue inflammation. Although expression of TLR3 in adipocytes has been found, the functional effects of TLR3 in adipose tissue are unknown. In the present study we aimed to investigate the role of TLR3 in obesity-induced adipose tissue inflammation and insulin resistance.

**Materials and methods:** Human adipose tissue biopsies were used to determine the expression of TLR3 and its correlation with markers for obesity and adipose tissue inflammation. In addition, adipose tissue inflammation as well as insulin sensitivity were determined in TLR3<sup>-/-</sup> and Wildtype (WT) that were fed a high fat diet (HFD) or low fat diet (LFD) for 16 weeks.

**Results:** In a large series of human fat tissue samples ( $n=76$ ), expression of TLR3 was significantly correlated with BMI and expression of leptin ( $r^2 = 0.15$  and  $0.08$ ;  $P < 0.01$ ), as well as expression of the pro-inflammatory cytokines IL-1 and TNF $\alpha$  ( $r^2 = 0.15$  and  $0.28$ ;  $P < 0.001$ ). TLR3 expression was highest in the adipocyte fraction as compared to the stromal vascular fraction in both the subcutaneous adipose tissue ( $1.00 \pm 0.26$  vs  $0.16 \pm 0.02$ ;  $P < 0.05$ ) and the visceral adipose tissue ( $1.03 \pm 0.17$  vs  $0.22 \pm 0.04$ ;  $P < 0.05$ ), suggesting a role of TLR3 in adipose tissue functioning. In response to HFD, TLR3<sup>-/-</sup> and WT mice had a similar increase in total body weight, but TLR3<sup>-/-</sup> mice displayed a reduction in white adipose tissue mass ( $-14\%$ ;  $P < 0.05$ ). Compared to LFD, HFD-feeding significantly increased *ex vivo* IL-6 secretion of adipose tissue explants (per mg tissue) derived from WT, while HFD did not affect IL-6 secretion of explants from TLR3<sup>-/-</sup> mice. Additionally, FACS analysis on the stromal vascular fraction showed that TLR3 deficiency blunted the HFD-induced increase in macrophages (F4/80+) content of adipose tissue. Remarkably, despite this reduction in adipose tissue inflammation, TLR3 deficient mice were not protected from HFD-induced systemic insulin resistance.

**Conclusion:** Our results show that the TLR3 is highly expressed in human adipose tissue and correlates with BMI as well as markers of adipose tissue inflammation. Animal studies reveal that TLR3 deficiency affects adipose tissue mass and protects against HFD-induced inflammation. These changes, however, do not translate into a reduction in systemic insulin resistance. As TLR3 is predominantly expressed in adipocytes (as opposed to stromal immune cells), TLR3 may be particularly involved in the early initiation of the inflammatory cascade in response to adipose tissue expansion.

## OP 12 Dynamics of beta cell signal transduction

### Caveolin-1 mediates the internalisation of functional insulin receptors in beta cells

T. Albrecht, G.E. Lim, I.R. Nabi, J.D. Johnson;  
Cellular and Physiological Sciences, University of British Columbia,  
Vancouver, Canada.

**Background and aims:** Type 2 diabetes is associated with defects in insulin receptor signalling, which has also been shown to cause beta-cell death. Thus, it is of fundamental importance to understand the mechanisms by which insulin transmits its pro-survival signals in beta-cells. The internalization of the activated insulin receptor (InsR) complex is necessary to initiate insulin signalling. The mechanisms of InsR internalization in beta-cells remain unclear, although Caveolin-1 (CAV1) has been implicated in other cell types. Our aim was to determine the proteins and membrane nanodomains involved in InsR internalization. Following the internalization of InsR in living cells required the development of novel fluorescent InsR fusion proteins because previous studies used InsR proteins labelled at the tyrosine kinase domain or the insulin-binding domain, which would disrupt signalling.

**Materials and methods:** We labelled the InsR with monomeric fluorescent proteins in a non-critical linker region between the furin-like region and the transmembrane domain. TagBFP and TagRFP fusion proteins were generated for Rab5, Rab7, Rab11, markers of endosomal populations. CAV1:RFP and LAMP2:GFP were employed to investigate an endocytic pathway and lysosomal degradation, respectively. We monitored InsR trafficking in MIN6 beta-cells using deconvolution microscopy, confocal microscopy, and fast live cell total internal reflection microscopy (TIRFM). Super-resolution stimulated emission depletion (STED) microscopy was applied to resolve the organization of membrane nanodomains harbouring the insulin receptor.

**Results:** TagRFP labelled InsR were shown to be fully functional via the assessment of ERK1/2 phosphorylation after 50 nM insulin treatment. The functionality of our novel InsR:TagRFP fusion protein was further confirmed by its co-internalization with fluorescently labelled insulin. To determine if CAV1 is involved in InsR internalization in the beta-cell we co-expressed fluorescently labelled CAV1:mTFP and InsR:TagRFP. TIRFM in living cells revealed that CAV1 is recruited to InsR membrane domains right before receptor internalization. These results were confirmed by STED microscopy, which showed a CAV1 protein coat around membrane nanodomains containing InsR. To investigate if CAV1 is essential for InsR internalization we compared the intracellular distribution of InsR in cells expressing CAV1 mutant proteins and RNAi. Indeed, MIN6 cells over-expressing dominant negative CAV1-Y14F:RFP showed defects in InsR internalization, with virtually complete accumulation of InsR at the plasma membrane. Conversely, cells over-expressing the dominant positive CAV1-Y14D:RFP mutant had excess InsR internalization into large vesicles, also strongly suggesting a requirement for CAV1 in InsR internalization. Effects of CAV1 mutants on the activation of Erk and Akt phosphorylation by insulin were investigated using Western blot. InsR:TagRFP-positive endosome populations were rapidly trafficked to lysosomes by a pathway that largely bypassed the classical Rab5 or Rab7 routes.

**Conclusion:** Taking advantage of our novel and validated InsR:TagRFP construct, we were able to monitor the dynamics of fully functional InsR in living beta-cells for the first time. We identified CAV1 as a key protein required for InsR internalization and elucidated the route of InsR within beta-cells. Together, our data give new insights on the mechanisms in InsR signalling.

### Chelation of $Zn^{2+}$ interferes with phasic insulin release by relieving feedback inhibition

O. Dyachok, A. Tengholm, E. Gylfe;  
Department of Medical Cell Biology, Uppsala University, Sweden.

**Background and aims:** Insulin hexamers form crystals with two coordinating zinc atoms within the  $\beta$ -cell granules. During exocytosis the crystals rapidly dissolve, releasing insulin and free  $Zn^{2+}$ . We have previously reported that released  $Zn^{2+}$  re-enters MIN6  $\beta$ -cells through voltage-dependent  $Ca^{2+}$  channels and inhibits insulin secretion (IS) by lowering cAMP. The present

study was undertaken to clarify the autocrine effect of  $Zn^{2+}$  on the kinetics of IS from mouse pancreatic islets.

**Materials and methods:** Epifluorescence microfluorometry and Meso Scale immunoassay were used for parallel measurements of the cytoplasmic  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$ ) and IS from groups of 3–5 superfused pancreatic islets loaded with the  $Ca^{2+}$  indicator Fura-2LR.  $Zn^{2+}$  feedback was prevented using the novel fast-acting extracellular  $Zn^{2+}$  chelator ZX-1 and the cell-permeable heavy metal chelator TPEN under conditions when IS from the islets were stimulated either with 20 mM glucose alone or with 30 mM KCl in the presence of 20 mM glucose and 250  $\mu$ M of the KATP channel activator diazoxide.

**Results:** Islets stimulated by rise of glucose from 3 to 20 mM reacted with initial reduction of  $[Ca^{2+}]_i$  followed by pronounced rise and fast oscillations from an elevated level. IS showed a distinct initial peak followed by a slowly rising second phase. Introduction of ZX-1 slightly reduced  $[Ca^{2+}]_i$ , converting the fast oscillations into very regular ones with increased frequency, and amplified secretion beyond the initial peak. These fast regular oscillations are reminiscent to those obtained with elevation of cAMP. When glucose was increased in the presence of ZX-1 the initial  $[Ca^{2+}]_i$  responses were followed by very regular fast  $[Ca^{2+}]_i$  oscillations. Under these condition both first and second phase secretion were pronounced and clearly separated. Omission of ZX-1 slightly raised  $[Ca^{2+}]_i$  and decreased frequency of the superimposed fast oscillation that also became less regular. To identify  $[Ca^{2+}]_i$ -independent effects of ZX-1 we performed experiments under conditions when  $[Ca^{2+}]_i$  is stably elevated by KCl depolarization.  $[Ca^{2+}]_i$  and IS were at basal levels in islets exposed to 20 mM glucose in the presence of diazoxide. Increase of the KCl concentration to 30 mM induced a prompt  $[Ca^{2+}]_i$  rise reaching a maximum in 25–40 sec and then settling at a somewhat lower constant elevation within 2 min. Parallel insulin measurements showed a similar pattern with an initial peak followed by sustained stimulation. Chelation of extracellular  $Zn^{2+}$  with 100  $\mu$ M ZX-1 caused a barely detectable reduction of the sustained  $[Ca^{2+}]_i$  level but IS was stimulated and even exceeded the initial peak. These effects were readily reversible and subsequent chelation of all  $Zn^{2+}$  with TPEN stimulated secretion without affecting  $[Ca^{2+}]_i$ . The  $[Ca^{2+}]_i$  pattern was almost identical when islets were depolarized with KCl in the presence of ZX-1 but IS increased to a sustained rate with a less distinct first peak. Subsequent omission of ZX-1 marginally raised  $[Ca^{2+}]_i$  but markedly reduced IS. The effects were reversed by reintroduction of ZX-1 and there was no additional effect of TPEN.

**Conclusion:** The present data show that trapping of  $Zn^{2+}$  co-released with insulin interferes with a negative feed-back loop that affects phasic release of the hormone. The findings are consistent with the concept that released  $Zn^{2+}$  re-enters the  $\beta$ -cell and inhibits secretion by lowering cAMP.

69

### Dynamic control of Epac2 localisation and Rap activity in glucose-stimulated beta cells

I. Jakobsson, O. Idevall-Hagren, A. Tengholm;  
Department of Medical Cell Biology, Uppsala, Sweden.

**Background and aims:** Glucose stimulation of insulin secretion involves elevation of the cytoplasmic  $Ca^{2+}$  and cAMP concentrations in pancreatic  $\beta$ -cells. The effects of cAMP are partly mediated by Epac2, which is a guanine nucleotide exchange factor for the Rap family of small GTPases. The aim of the present study was to investigate how glucose and cAMP affects the subcellular localization of Epac2 and the activity of Rap GTPases in the  $\beta$ -cell.

**Materials and methods:** Immunocytochemistry and confocal imaging was used to determine the subcellular localization of endogenous Epac2. Fluorescent protein-tagged Epac2 and evanescent wave microscopy enabled dynamic imaging of plasma membrane association of the protein in MIN6-cells and primary mouse  $\beta$ -cells. Epac2 mutants unable to interact with cAMP or Ras were generated by introducing point mutations in their binding domains. The localization of active Rap was visualized with a green fluorescent protein-tagged Rap-GTP binding protein domain (GFP-RaGDS<sub>RBD</sub>).

**Results:** In unstimulated cells exposed to 3 mM glucose Epac2 was distributed in the cytoplasm. Elevation of the glucose concentration to 11 or 20 mM triggered translocation of Epac2 to the plasma membrane in both MIN6 cells and primary mouse  $\beta$ -cells. The translocation was often cyclic with a periodicity of 2–8 minutes, reminiscent of the cAMP and  $Ca^{2+}$  oscillations observed in glucose-stimulated  $\beta$ -cells. Elevation of the intracellular cAMP concentration with 100  $\mu$ M of the phosphodiesterase inhibitor IBMX or by direct application of cAMP to cells permeabilized with  $\alpha$ -toxin also triggered plasma membrane translocation of Epac2. Mutation of the N-terminal, low-

affinity cAMP-binding site of Epac2 did not affect translocation. In contrast, substitution of a single amino acid residue in the high-affinity cAMP-binding site abolished the Epac2 translocation in response to cAMP. Similarly, a point mutation in the Ras association domain also prevented translocation of Epac2 in response to cAMP elevation. Epac2 translocation was associated with activation of Rap at the plasma membrane, since an increase of the glucose concentration from 3 to 11 or 20 mM or elevation of intracellular cAMP with IBMX induced membrane translocation of the Rap activity reporter GFP-RalGDS<sub>RBD</sub>. Glucose-induced Rap activity often showed distinct oscillations in both MIN6-cells and primary mouse  $\beta$ -cells.

**Conclusion:** Glucose stimulation of  $\beta$ -cells induces cyclic Epac2 translocation to the plasma membrane. The translocation requires intact high-affinity cAMP-binding- and Ras-association domains of the protein. The resulting cyclic activation of Rap activity at the plasma membrane is likely involved in the generation of pulsatile insulin secretion.

### Physiological concentrations of GLP-1 increase insulin secretion by activating protein kinase C pathway in pancreatic beta cells

M. Shigeto<sup>1,2</sup>, R. Ramracheya<sup>1</sup>, N. Rorsman<sup>1</sup>, M. Katsura<sup>2</sup>, B. Thorens<sup>3</sup>, K. Kaku<sup>2</sup>, P. Rorsman<sup>1</sup>;

<sup>1</sup>University of Oxford, UK, <sup>2</sup>Department of Diabetes, Endocrinology and Metabolism, Kawasaki Medical School, Kurashiki, Japan, <sup>3</sup>Physiology, University of Lausanne, Switzerland.

**Background and aims:** The peripheral basal blood concentration of GLP-1 (Glucagon like peptide-1) is in the picomolar range. Moreover, administration of dipeptidyl peptidase (DPP)-IV inhibitors increase the peripheral blood concentration of GLP-1 by only a few picomolar and yet results in significant anti diabetic effects. However, most *in vitro* experiments studying the effect of GLP-1 routinely use nanomolar concentrations. We have previously reported that a low concentration (1 pM) of GLP-1 stimulated insulin secretion through a cAMP-PKA (cyclic AMP-protein kinase A) independent pathway in mouse  $\beta$ -cells. In this study, we tried to identify this signalling pathway by which the physiological concentrations of GLP-1 affect insulin secretion from primary  $\beta$ -cells. We now confirm that GLP-1 induced insulin secretion have PKC (protein kinase C) dependent pathway and L-type calcium channel is involved in the pathway.

**Materials and methods:** Mouse islets were isolated by collagenase digestion. Secreted insulin was quantified using the RIA kit. Dispersed cells were plated on plastic tissue culture dishes for electrophysiological recordings. Recordings were performed using the perforated-patch whole-cell configuration. Experiments of GLP-1 receptor knockout mice were performed in University of Lausanne. Data are presented as mean  $\pm$  SEM. Statistical significance was evaluated using the Student t-test.

**Results:** GLP-1 (1 pM) stimulated insulin secretion from perfused mouse pancreas (N=8) and isolated islets ( $16.3 \pm 1.6$  vs  $23.0 \pm 4.0$  pg/islet/h, N=7,  $p < 0.05$ ). GLP-1 also increased  $\beta$ -cell membrane capacitance ( $6.8 \pm 4.45$  vs  $35.8 \pm 17.7$  fF, N=5,  $p < 0.05$ ) and calcium current ( $I_{Ca}$ :  $2.61 \pm 0.46$  vs  $3.21 \pm 0.59$ , N=7,  $p < 0.05$ ) on single  $\beta$ -cell. The effect was completely inhibited by addition of GLP-1 receptor blocker, exendin9-39 (100 nM). Insulin secretion induced by 10 nM GLP-1 was inhibited by PKA inhibitor, RP-cAMPS (100  $\mu$ M), while 1 pM GLP-1 was still significantly increased insulin secretion ( $16.3 \pm 1.6$  vs  $22.6 \pm 4.3$  pg/islet/h, N=9,  $p < 0.05$ ) and  $I_{Ca}$  ( $1.93 \pm 0.19$  vs  $2.24 \pm 0.18$ , N=5,  $p < 0.05$ ). The PKC inhibitor, bisindolylmaleimide (100 nM) and calphostin C (100 nM), blocked the effect of 1 pM GLP-1 on insulin secretion and  $I_{Ca}$ . GLP-1 stimulated insulin secretion was significantly inhibited by L-type calcium channel blocker, isradipine (2  $\mu$ M). Surprisingly, GLP-1 further decreased calcium currents in the presence of isradipine ( $0.678 \pm 0.09$  vs  $0.59 \pm 0.09$ , N=5,  $p < 0.05$ ). Neither 1 pM nor 10 nM stimulated insulin secretion from islets of GLP-1 receptor knockout mice. One pM of GLP-1 increased insulin secretion ( $63.2 \pm 11.5$  vs  $121.1 \pm 23.2$  pg/islet/h, 2 donors,  $p < 0.05$ ) and  $I_{Ca}$  ( $3.66 \pm 1.14$  vs  $4.07 \pm 1.17$ , N=5,  $p < 0.05$ ) on human.

**Conclusion:** The results demonstrate that physiological concentrations of GLP-1 increases insulin secretion, and suggest that PKC and L-type calcium channel are involved in its signal pathway in mouse. It would appear that both PKA and PKC pathway are working with concerted efforts *in vivo*.

## 71

### Involvement of phosphodiesterases in the shaping of sub-membrane-cAMP signals and pulsatile insulin secretion

G. Tian, J. Sageterp, A. Tengholm;

Medical cell biology, Uppsala University, Sweden.

**Background and aims:** Cyclic AMP (cAMP) regulates numerous cell functions, including insulin secretion from pancreatic  $\beta$ -cells. Specificity and versatility of cAMP signalling are determined by the spatial localization and temporal dynamics of the signal. Phosphodiesterases (PDEs) are important terminators of cAMP signals by degrading the nucleotide. In  $\beta$ -cells, glucose triggers oscillations of the cAMP concentration beneath the plasma membrane ([cAMP]<sub>pm</sub>) which are important for kinetic control of insulin secretion, but the mechanisms underlying the oscillations are poorly understood. The aim of this study was to clarify the role of different PDEs for the generation of [cAMP]<sub>pm</sub> oscillations in glucose-stimulated  $\beta$ -cells.

**Materials and methods:** A translocation biosensor based on fluorescence-tagged subunits of protein kinase A was used to monitor [cAMP]<sub>pm</sub> in insulin-secreting MIN6 cells and mouse pancreatic  $\beta$ -cells. The time-course of insulin secretion from single MIN6 cells was monitored using a translocation sensor for PtdIns(3,4,5)P<sub>3</sub>, which is formed in the plasma membrane following autocrine insulin receptor activation. Changes in localization of the biosensors were detected with total internal reflection fluorescence microscopy. Pharmacological agents were used to achieve family-selective PDE inhibition, and lentiviral vectors expressing shRNA to knock-down PDE8B.

**Results:** [cAMP]<sub>pm</sub> was low and stable in  $\beta$ -cells exposed to basal medium containing 3 mM glucose. The general PDE inhibitor IBMX caused a prompt increase of [cAMP]<sub>pm</sub>. While oscillations were frequently observed at 50  $\mu$ M IBMX, 300  $\mu$ M of the inhibitor most often caused stable [cAMP]<sub>pm</sub> elevation. In both MIN6- and islet  $\beta$ -cells inhibition of transmembrane adenylyl cyclases with 100  $\mu$ M 2',5'-dideoxyadenosine (DDA) resulted in marked suppression of [cAMP]<sub>pm</sub> despite the presence of IBMX, indicating the involvement of IBMX-insensitive mechanisms in cAMP degradation. Among IBMX-sensitive PDEs, PDE3 was most important for maintaining a low [cAMP]<sub>pm</sub> under basal conditions in both the clonal and primary  $\beta$ -cells. After glucose induction of [cAMP]<sub>pm</sub> oscillations, inhibitors of PDE1, -3 and -4 increased the average [cAMP]<sub>pm</sub>, but typically did not prevent the oscillations in either type of  $\beta$ -cells. Gene silencing by shRNA was used to assess a role of the IBMX-insensitive isoform PDE8B in glucose-induced [cAMP]<sub>pm</sub> signaling. Knockdown of PDE8B expression in MIN6-cells resulted in increased basal [cAMP]<sub>pm</sub> and prevention of the [cAMP]<sub>pm</sub>-lowering effect of DDA after IBMX exposure. Furthermore, PDE8B knockdown perturbed the glucose-induced [cAMP]<sub>pm</sub> oscillations and increased insulin secretion with loss of the normal pulsatility.

**Conclusion:** [cAMP]<sub>pm</sub> oscillations in  $\beta$ -cells are caused by cyclic variations in the rate of cAMP production. Several PDEs, including the IBMX-insensitive PDE8B, are involved in shaping the sub-membrane cAMP signals and pulsatile insulin secretion.

### The scaffold protein beta-arrestin 2 is involved in the modulation of pancreatic beta cell mass

M.A. Ravier<sup>1</sup>, N. Linck<sup>1</sup>, A. Varrault<sup>1</sup>, N. Piro<sup>2</sup>, A. Tamazouzt<sup>1</sup>, S. Dalle<sup>1</sup>, G. Bertrand<sup>1</sup>;

<sup>1</sup>Institut de Genomique Fonctionnelle, Montpellier, <sup>2</sup>Réseau d'Histologie Expérimentale de Montpellier, France.

**Background and aims:** The autocrine action of insulin on its own receptor was shown to be critical for the maintenance of normal pancreatic  $\beta$ -cell function and mass. It has been reported that downstream of the insulin receptor signalling, besides the conventional IRS/PI3K/Akt pathway, a second pathway involving  $\beta$ -arrestin 2 ( $\beta$ -arr2) is required to induce a full Akt activation in hepatocytes, and that any deficiency of this signal contributed to the development of insulin resistance. As we have observed similar mechanisms in pancreatic  $\beta$ -cells, the aim of our study was to investigate the functional role of  $\beta$ -arr2 in pancreatic  $\beta$ -cells using  $\beta$ -arr2 KO mice.

**Materials and methods:**  $\beta$ -arr2 KO mice and their wild-type (WT) littermates were fed with either a standard diet (5 kcal% fat) or a high fat diet (HFD, 45 kcal% fat) from weaning for 22-25 weeks. Islet size and areas were determined by morphometric analysis from sections of paraffin embedded pancreas stained with hematoxylin and eosin.  $\beta$ -cell mass and islet architec-

ture were assessed by immunofluorescence.  $\beta$ -arr2 expression was evaluated in isolated islet by quantitative real time-PCR and Western blotting.

**Results:** In  $\beta$ -arr2 KO mice, insulin secretion in response to glucose was not affected, while the insulin content of pancreas and islets, as well as the mRNA level of Ins2 in islets, were decreased by about 25% ( $p < 0.05$ ), suggesting a role for  $\beta$ -arr2 in the modulation of  $\beta$ -cell mass. Indeed, morphometric histological analysis of pancreatic sections showed a reduction of the total islet area (30%,  $p < 0.05$ ) in  $\beta$ -arr2 KO mice, due to a modified distribution of islet sizes with an increased proportion of small islets ( $< 0.002 \text{ mm}^2$ ,  $p < 0.01$ ) and a reduction of large islets ( $> 0.01 \text{ mm}^2$ ,  $p < 0.05$ ). On the other hand, immunohistochemical staining of insulin and glucagon did not show any abnormalities in islet architecture but, in keeping with reduced islet size, indicated a decrease in  $\beta$ -cell number (35%,  $p < 0.01$ ), and therefore  $\beta$ -cell mass. Furthermore,  $\beta$ -arr2 mRNA and protein expression were down regulated by 25% ( $p < 0.05$ ) in pancreatic islets of WT mice fed with a high fat diet (HFD). Remarkably, under HFD, while WT littermate mice displayed a doubling of their islet area,  $\beta$ -arr2 KO mice were unable to compensate their  $\beta$ -cell mass ( $p < 0.05$ ).

**Conclusion:** The scaffold protein  $\beta$ -arr2 plays a role in the maintenance of  $\beta$ -cell mass in normal conditions. A reduced expression of the protein in insulin resistant state might prevent the compensatory  $\beta$ -cell mass expansion occurring in type 2 diabetes.

### Pioglitazone versus berberine for treatment of non-alcoholic fatty liver disease patients with impaired glucose regulation or type 2 diabetes mellitus

H. Yan<sup>1</sup>, M. Xia<sup>1</sup>, X. Chang<sup>1</sup>, H. Bian<sup>1</sup>, Q. Xu<sup>1</sup>, X. Gao<sup>1</sup>, Y. Tu<sup>2</sup>, W. Jia<sup>3</sup>, W. Deng<sup>3</sup>;

<sup>1</sup>Endocrinology and Metabolism, Zhongshan Hospital, Fudan University,

<sup>2</sup>Endocrinology and Metabolism, The sixth people's hospital, Shanghai

Jiaotong University, <sup>3</sup>School of public health, Fudan University, Shanghai, China.

**Background and aims:** To assess the effect and safety of pioglitazone (PGZ) or berberine (BBR) on Non-Alcoholic Fatty Liver Disease (NAFLD) patients with impaired glucose regulation (IGR) or diabetes mellitus (DM).

**Materials and methods:** Totally 184 subjects were enrolled in a randomized, open, controlled clinical trial with a 16-week period of follow-up. All the participants were diagnosed as NAFLD and IGR or DM, and were divided into three groups randomly: Group A received lifestyle intervention (LI) without any drugs ( $n=62$ ); Group B received LI and PGZ (15 mg qd.) ( $n=60$ ); Group C received LI and BBR (0.5g tid) ( $n=62$ ). All of them were treated for 16 weeks. The primary outcome was an improvement of metabolism, including fasting glucose, 2 hour glucose, HbA1c, lipid profile [total cholesterol (TC), triglyceride (TG), HDL-c, LDL-c], liver enzymes [alanine aminotransferase (ALT), aspartate aminotransferase (AST), glutamyltransferase (GGT)]. The secondary outcome was a reduction in liver fat content detected by proton magnetic resonance spectroscopy (<sup>1</sup>H MRS).

**Results:** The three groups were well matched in demographic characteristics, clinic and most of laboratory data, liver fat content and other aspects. Compared with pre-treatment data, subjects had significant improvement in HbA1c, liver fat content, ALT, AST, GGT, weight, waist circumference, WHR, diastolic blood pressure (of group A,B,C), fasting glucose, 2-hour glucose, systolic blood pressure (of group B,C), HDL-c (only group B), TC, TG, LDL-c (only group C) after 16 weeks treatment (all paired  $t$ -test  $p < 0.05$ ). Group B (-41.02%) and Group C (-51.30%) had more obvious reduction in liver fat content (percentage decline relative to the baseline) than Group A (-27.98%) (ANOVA  $p=0.034$ ), and the difference between group C and group A was statistically significant (Dunnett test  $p=0.035$ ). In multiple comparisons, PGZ therapy had a significantly higher reduction than LI in 2-hour glucose, ALT (all  $p < 0.05$ ). While BBR therapy, compared with LI, had a significantly higher reduction in TC, TG, ALT, weight, waist circumference, diastolic blood pressure (all  $p < 0.05$ ). Although PGZ or BBR therapy had significantly higher reduction in FBG, HbA1c, HDL-c, LDL-c, AST, GGT, systolic blood pressure, WHR, compared with LI, the differences of the three groups were not statistically significant (all  $p > 0.05$ ). The total incidence of adverse reactions of PGZ and BBR were 23.33% and 43.55% respectively. The major side effects of PGZ were muscle pain (26.32%), palpitations (10.53%), fatigue (10.53%). The major side effects of BBR were digestive symptoms such as anorexia (30.95%), diarrhea (19.05%), severe constipation (11.90%).

**Conclusion:** For NAFLD patients with IGR or DM, lifestyle intervention with or without pioglitazone or berberine are effective methods to improve glucose metabolism, reduce liver fat content and liver enzymes. Berberine is superior to lifestyle intervention and pioglitazone for improvement of lipid profile, weight, waist circumference and blood pressure. Both pioglitazone and berberine are well tolerated.

### The effect of frequency of meals on hepatic fat content in patients with type 2 diabetes

L. Belinova<sup>1</sup>, H. Kahleova<sup>1</sup>, M. Hajek<sup>2</sup>, M. Dezortova<sup>2</sup>, M. Hill<sup>3</sup>, T. Pelikanova<sup>1</sup>;

<sup>1</sup>Department of Diabetes, Institute for Clinical and Experimental Medicine,

<sup>2</sup>Radiodiagnostic and Interventional Radiology Department, Institute for

Clinical and Experimental Medicine, <sup>3</sup>Institute of Endocrinology, Prague, Czech Republic.

**Background and aims:** Increased hepatic fat content is associated with type 2 diabetes (T2D). Caloric restriction is crucial in its treatment typically appor-

tioned into five or six small meals during the day. The aim of our study was to compare the effect of six meals vs. two meals a day with the same caloric restriction on hepatic fat content in subjects with T2D.

**Materials and methods:** In a randomized, crossover study, we assigned 54 patients with T2D to follow two regimens of a hypocaloric diet (-500 kcal/day), each for 12 weeks: six meals a day (A), and two meals a day (B). The diet in both regimens had the same macronutrient and energy content. We measured the hepatic fat content by the proton magnetic resonance spectroscopy performed by 3T MR scanner (Magnetom - Trio Siemens). Spectra were obtained from three different parts of the liver. Signal intensities were used for determining fat content. Then the fat total signal area (FTSA) ratio was calculated. For statistical analysis, 2x2 crossover ANOVA and Pearson's correlations were used.

**Results:** FTSA was reduced in response to both regimens ( $p<0.001$ ), more in B (-3.4; 95% CI, -3.8 to -3.1 % in A vs. -4.2; 95% CI, -4.5 to -3.8 % in B;  $p=0.03$ ). Body-mass-index (BMI) was reduced in both regimens ( $p<0.001$ ), more in B (-0.82; 95% CI -0.94 to -0.69 kg.m<sup>-2</sup> in A vs. -1.23; 95% CI -1.4 to -1.17 kg.m<sup>-2</sup> in B;  $p<0.001$ ). Fasting glycemia decreased in both regimens ( $p<0.001$ ), more in B (-0.47; 95% CI -0.57 to -0.36 mmol/l in A vs. -0.78; 95% CI -0.89 to -0.68 mmol/l in B;  $p=0.004$ ). Decrease in FTSA correlated strongly positively with decrease in fasting glycemia ( $r=+0.56$ ;  $p<0.001$ ). After adjustment for changes in BMI this association remained significant ( $r=+0.28$ ;  $p=0.05$ ).

**Conclusion:** Prolonged fasting reduced hepatic fat content more than a diet with the same caloric restriction divided in more frequent meals in patients with T2D. This reduction was associated with a decrease in fasting glycemia, independently on changes in BMI.

### The effect of frequency of meals on body weight, HbA<sub>1c</sub> and resting energy expenditure in patients with type 2 diabetes

H. Kahleova<sup>1</sup>, L. Belinova<sup>1</sup>, M. Hill<sup>2</sup>, T. Pelikanova<sup>1</sup>;

<sup>1</sup>Diabetes Centre, Institute for Clinical and Experimental Medicine,

<sup>2</sup>Institute of Endocrinology, Prague, Czech Republic.

**Background and aims:** Caloric restriction is crucial in the treatment of type 2 diabetes (T2D), typically (but not necessarily) apportioned into five or six small meals during the day. It has been shown that a large isocaloric mixed meal causes a greater postprandial thermogenic response than the same food consumed in six smaller portions. The aim of our study was to compare the effect of six vs. two meals a day with the same caloric restriction on body weight, HbA<sub>1c</sub> and resting energy expenditure in subjects with T2D.

**Materials and methods:** In a randomised, crossover study, we assigned 54 patients with T2D to follow two regimens of a hypocaloric diet (-500 kcal/day), each for 12 weeks: six meals a day (A), and two meals a day (B). The diet in both regimens had the same macronutrient and energy content. At weeks 0, 12 and 24, we measured subject weight, HbA<sub>1c</sub> and performed indirect calorimetry using metabolic monitor VMAX; Sensor Medics, Anaheim, CA, USA. Predicted resting energy expenditure (REE) was counted according to Harris-Benedict equation. For statistical analysis, 2x2 crossover ANOVA was used.

**Results:** Body weight decreased in both regimens ( $p<0.001$ ), more in B (-2.3; 95% CI -2.7 to -2.0 kg in A vs. -3.7; 95% CI -4.1 to -3.4 kg in B;  $p<0.001$ ). HbA<sub>1c</sub> decreased in both regimens ( $p<0.001$ ) with a trend toward a greater decrease in B (-0.23; 95% CI -0.27 to -0.19 % in A vs. -0.25; 95% CI -0.29 to -0.20 % in B;  $p=0.08$ ). Fasting C-peptide decreased in both regimens ( $p<0.001$ ), more in B ( $p=0.05$ : -0.14; 95% CI -0.18 to -0.1 vs. -0.05; 95% CI -0.09 to -0.01 nmol/L in A). HbA<sub>1c</sub> decreased in both regimens ( $p<0.001$ ); the trend toward the greater decrease in B was not significant ( $p=0.08$ : -0.25; 95% CI -0.29 to -0.20 vs. -0.23; 95% CI -0.27 to -0.19 % in A). Plasma immunoreactive insulin, triglycerides and LDL-cholesterol decreased comparably in both regimens. No significant change in total or HDL-cholesterol was observed in either regimen. Respiratory quotient increased in both regimens ( $p<0.01$ ) with a trend toward a greater increase in A (+0.06; 95% CI +0.04 to +0.07 in A vs. +0.04; 95% CI +0.02 to +0.05 in B;  $p=0.2$ ). Measured REE decreased in both regimens ( $p<0.001$ ) with a trend toward a greater decrease in A (-108.3; 95% CI -125.3 to -91.5 kcal/day in A vs. -90.8; 95% CI -107.5 to -74.3 kcal/day in B;  $p=0.3$ ). If counted as percentage of the predicted REE according to Harris Benedict equation, REE decreased in both regimens ( $p<0.001$ ), with a trend toward a greater decrease in A (-4.6; 95% CI -5.6 to -3.7 % in A vs. -3.0; 95% CI -3.9 to -2.1 % in B;  $p=0.08$ ).

**Conclusion:** Two meals a day reduced body weight, fasting glycemia and plasma C-peptide more than a diet with the same caloric restriction divided

in six more frequent meals in patients with T2D. Our data suggest that fewer bigger meals may be better than smaller ones during the day for patients with T2D.

## 76

### A MUFA diet reduces liver fat in type 2 diabetes patients in absence of weight loss and independently of postprandial lipaemia

L. Bozzetto<sup>1</sup>, G. Annuzzi<sup>1</sup>, L. Costagliola<sup>1</sup>, A. Prinster<sup>2</sup>, A. Giacco<sup>1</sup>,

A. Mangione<sup>1</sup>, P. Cipriano<sup>1</sup>, L. Patti<sup>1</sup>, C. Vigorito<sup>3</sup>, G. Riccardi<sup>1</sup>, A.A. Rivellese<sup>1</sup>;

<sup>1</sup>Department of Clinical and Experimental Medicine, Federico II University,

<sup>2</sup>Institute of Biostructure and Bioimaging, National Research Council,

<sup>3</sup>Department of Clinical Medicine, Cardiovascular and Immunological Sciences, Federico II University, Naples, Italy.

**Background and aims:** Liver steatosis is associated with higher risk of type 2 diabetes (T2DM) and postprandial lipid abnormalities. No studies have evaluated the effects of isocaloric lifestyle interventions on hepatic fat content and postprandial lipid metabolism. Therefore the aims of the present study were to evaluate the effects of two generally recommended diets with/without an aerobic exercise training on liver fat content and postprandial lipaemia in the absence of weight loss in T2DM.

**Materials and methods:** Forty-five T2DM patients in satisfactory blood glucose control (HbA<sub>1c</sub> 6.6±0.8%), aged 35-70 years, were randomized to an 8-week treatment with: high carbohydrate/high fibre/low glycemic index diet (CHO/fibre group), or high MUFA diet (MUFA group), or high carbohydrate/high fibre/low glycemic index diet plus physical activity program (CHO/fibre+Ex group), or high MUFA diet plus physical activity program (MUFA+Ex group). Physical activity program consisted in two 45 min sessions per week of supervised light/medium intensity exercise. Before and after intervention hepatic fat content was measured by proton magnetic resonance spectroscopy. Triglyceride-rich lipoproteins (TRL), separated by preparative sequential ultracentrifugation, were evaluated at fasting and over six hours after a test meal of similar composition to the run-in diet at baseline and to the assigned diet at the end of the intervention.

**Results:** Dietary compliance was optimal and body weight remained stable during the intervention in all groups. Liver fat decreased significantly more in MUFA (-29%) and MUFA+Ex (-25%) than in CHO/fibre (-4%) and CHO/fibre+Ex groups (-6%) ( $p=0.006$ ). TRL triglyceride postprandial incremental AUC decreased in CHO/fibre (-36%) and increased in CHO/fibre+Ex (+9%), MUFA (+29%) and MUFA+Ex (+54%) ( $p=0.004$ ).

**Conclusion:** A MUFA rich diet induced a clinically relevant reduction in hepatic fat in T2DM in the absence of body weight loss and independently of a light/medium intensity supervised exercise program. This MUFA effect was not related to an improvement in postprandial lipaemia.

Clinical Trial Registration Number: NCT01025856

### Effects of $\omega$ 3 and $\omega$ 6 polyunsaturated fatty acids supplementation on plasma circulating metabolic markers and adipose tissue oxidative stress in fructose-fed rats

K. Louchami<sup>1</sup>, Z. Mellouk<sup>2</sup>, W. Malaisse<sup>1</sup>, A. Sener<sup>1</sup>, D. Ait Yahia<sup>2</sup>;

<sup>1</sup>Laboratory of Experimental Hormonology, Free University of Brussels,

Belgium, <sup>2</sup>Department of Biology, Es-Sénia University, Oran, Algeria.

**Background and aims:** High intake of dietary fructose has been shown to exert a number of adverse metabolic effects in humans and experimental animals.  $\omega$ 3 and  $\omega$ 6 polyunsaturated fatty acids have been the subject of extensive investigation regarding their possible benefit effects on components of the metabolic syndrome. The aim of the present study was to examine whether  $\omega$ 3 or  $\omega$ 6 polyunsaturated fatty acids supplementation improves insulin resistance, plasma circulating metabolic markers as well as oxidative stress in adipose tissue in high-fructose-fed rats.

**Material and methods:** Twenty four female Wistar rats were exposed to diets containing either 64% (w/w) starch and 5% sunflower oil (Ssun), or 64% fructose and either 5% sunflower oil (Fsun), 3.4% sunflower oil and 1.6% salmon oil (Fsal), or 3.4% sunflower oil and 1.6% safflower oil (Fsal) for 8 weeks. Blood pressure and plasma glucose, insulin, triglycerides and leptin were determined. Moreover, hepatic glucokinase and glycogen and adipose tissue lipid (TBARS, hydroperoxides) and protein (carbonyls) oxidation, ni-

tric oxide (NO) as well as antioxidant enzymes such as superoxide dismutase (SOD), catalase (CAT) and glutathione reductase (GSH-Red) were measured. **Results:** After 2 months of experiment, Fsun rats exhibited higher blood pressure and plasma triglycerides, leptin and HbA1C as compared to Ssun rats. Plasma glucose, insulin, insulinogenic index and HOMA-IR were similar between these two groups. Liver glucokinase activity and glycogen levels were significantly lower in Fsun than in Ssun. In addition, administration of fructose to rats led to high adipose tissue TBARS, hydroperoxides, carbonyls and low NO levels relative to Ssun animals. Adipose tissue SOD, CAT and GSH-Red activities were lower in Fsun rats than in Ssun rats. Treatment of fructose rats with  $\omega 3$  or  $\omega 6$  reduced significantly blood pressure, triglycerides, leptin and HbA1C but little affected plasma insulin and insulinogenic index as compared to Fsun. Hepatic glucokinase and glycogen were greater only in Fsal group as compared to Fsun. Moreover, a decrease in TBARS, hydroperoxides, and carbonyls were observed with  $\omega 3$  and  $\omega 6$  supplementation. Feeding Fsal diet enhanced NO contents in adipose tissue. Additionally, SOD and GSH-Red activities were greater in Fsal and Fsaf groups, while CAT was higher only in Fsal group as compared to Fsun group.

**Conclusion:** These results suggest that dietary supplementation with  $\omega 3$  and  $\omega 6$  polyunsaturated fatty acids to fructose rats alleviated the effects of fructose by lowering blood pressure, HbA1C, triglyceride and leptin levels. On the other hand,  $\omega 3$  and  $\omega 6$  consumption improved the oxidative stress by decreasing lipid and protein oxidation and enhancing antioxidant enzymes. Hence  $\omega 3$  and  $\omega 6$  can be used as nutraceutical nutrients for the prevention and/or management of metabolic syndrome and disorders related to it.

## 78

### Overfeeding with polyunsaturated fat causes distinct effects on liver and body fat accumulation compared with saturated fat: a randomised controlled trial

U. Risérus<sup>1</sup>, F. Rosqvist<sup>1</sup>, D. Iggman<sup>1</sup>, J. Kullberg<sup>1</sup>, L. Johansson<sup>1</sup>, H.-E. Johansson<sup>1</sup>, I. Dahlman<sup>2</sup>, P. Arner<sup>2</sup>, H. Ahlström<sup>3</sup>;

<sup>1</sup>Public health and caring sciences, Uppsala University, <sup>2</sup>Medicine, Karolinska Institutet, Stockholm, <sup>3</sup>Uppsala University, Sweden.

**Background and aims:** We have recently shown that n-6 PUFA reduces liver fat content and improve metabolic disorders compared with saturated fats under weight stable conditions. It is however unclear whether dietary fat composition could determine the body deposition and distribution during moderate weight gain. We aimed to investigate the effects on body composition during overfeeding with either saturated or n-6 polyunsaturated fat.

**Materials and methods:** Thirty-nine lean (mean BMI: 20.7±2.1), young (mean age: 27±4) men and women were overfed for 7 weeks by adding muffins to their regular diet. Subjects were randomized in a double-blind manner to either consume muffins high in saturated fatty acids (SFA-diet; palm oil) or n-6 polyunsaturated fatty acids (PUFA-diet; sunflower oil). Apart from fatty acid composition, the content of fibre, total fat, carbohydrate and protein were identical in all muffins. The amount of muffins consumed was individually adjusted with a targeted weight gain of 3%. Body composition including liver fat, visceral and subcutaneous abdominal adipose tissue (VAT and SAT, respectively) total adipose tissue (TAT) and lean tissue was measured with and magnetic resonance imaging (MRI).

**Results:** There were no differences between groups at baseline in liver fat, VAT, SAT, TAT or lean tissue (all P>0.1). Both groups consumed a similar amount of additional energy (+750 kcal/day) and gained similarly in body weight (1.6±0.9 kg, p=0.94 for difference between groups) representing a mean percentage weight gain of ~2.6%. The subjects on the SFA-diet however had a ~6-fold higher increase in liver fat, and a ~2-fold higher increase in VAT and TAT compared with the subjects on the PUFA-diet (all P<0.05 for diff between groups). In contrast, the PUFA-diet had a two-fold higher increase in lean tissue (p<0.05; 0.86±0.62 litres and 0.31±0.68 litres, respectively).

**Conclusion:** During overfeeding, excess calories from n-6 PUFA causes less liver and abdominal fat deposition and more lean tissue gain than excess calories from saturated fat. This is the first evidence in humans to suggest distinct effects of dietary fatty acids on body composition during weight gain. The implications of these findings for the prevention of obesity and type 2 diabetes in the population warrants further investigation.

## OP 14 Can we improve outcomes in diabetic pregnancy?

### 79

#### Atlantic DIP: what does selective screening for gestational diabetes miss?

G.M. Healy<sup>1</sup>, A. Vellinga<sup>2</sup>, L. Carmody<sup>1</sup>, G. Avalos<sup>2</sup>, E. Mustafa<sup>1</sup>, S. Khalil<sup>1</sup>, E. Noctor<sup>1</sup>, B. Kirwan<sup>1</sup>, F.P. Dunne<sup>1,2</sup>;

<sup>1</sup>Department of Endocrinology, University College Hospital,

<sup>2</sup>School of Medicine, National University of Ireland, Galway, Ireland.

**Background and aims:** Gestational diabetes mellitus (GDM) is the most common medical complication of pregnancy, with prevalence ranging 4–16% internationally. It leads to adverse foetal and maternal outcomes, which large studies have shown can be significantly reduced with treatment. There is debate about whether universal or risk-factor based screening is most appropriate but the International Association of Diabetes and Pregnancy Study Groups (IADPSG) recommends universal screening in populations with a high population prevalence of Type 2 diabetes. The ATLANTIC Diabetes in Pregnancy (DIP) group studies GDM across the population of the Atlantic coast of Ireland. The aim of this study was to compare pregnancy outcomes for universal screening (US) compared to selective screening (SS) for GDM based on Irish guidelines.

**Materials and methods:** During 2007–2008, US was employed and during 2009–2010 a SS approach was used, which included women on the basis of body mass index, age, family history, pregnancy history and ethnicity. Both strategies utilised a 2 hour 75g Oral Glucose Tolerance Test (OGTT) using IADPSG cut off values. The population was categorised into three groups: Normal Glucose Tolerance from the universal screening (NGT - US), GDM from universal screening (US-GDM) and GDM from selective screening (SS-GDM). The pregnancy outcomes according to screening strategy were compared.

**Results:** During US 5286 women were screened, 557 (10.5%) were diagnosed with GDM. During SS, 562 were screened and 465 were identified as having GDM. In view of the SS criteria, women who underwent SS were older and had a greater BMI at screening point (P<0.01). However more women in the in SS received their diagnosis after > 28 weeks of gestation (45.7% Vs 32.9 % P<0.001). The percentages of adverse events detected were lowest in the US - NGT group, higher in the SS- GDM group and highest in the US- GDM group (Table 1). If we assume US is the gold standard and detects the population prevalence for adverse outcomes in GDM pregnancies, the results of this study show that SS potentially misses 2.1% of GDM associated pre-eclampsia, 7.3% GDM associated adverse birth outcomes and 6.9% of the GDM associated neonatal admissions.

**Conclusion:** SS does not identify all women with GDM and thus, cases of pre-eclampsia, neonatal morbidities and neonatal unit admissions are not being correctly assigned to GDM. These women and newborns miss the opportunity for timely diagnosis and appropriate evidence based interventions which may limit adverse pregnancy outcomes and influence future health of the mother and her offspring.

Table 1: Comparison of outcomes in the three groups

	US-NGT (%)	SS-GDM (%)	US-GDM (%)	X <sup>2</sup> Trend
Pre-eclampsia	180 (4.0)	24 (5.4)	41 (7.5)	0.00
Macrosomia	158 (3.4)	21 (4.6)	27 (4.9)	0.04
LGA	763 (16.3)	89 (19.5)	121 (21.8)	0.01
Adverse Birth outcomes	694 (14.7)	112 (24.1)	175 (31.4)	0.00
NNU	324 (6.9)	70 (15.8)	123 (22.7)	0.00

<sup>1</sup>Department of Diabetes and Endocrinology, <sup>2</sup>Department of Biostatistics and Medical Computing, Saint-Louis University Hospital, University Paris-Diderot Paris-7, Paris, France, <sup>3</sup>Department of Diabetes and Endocrinology, Bichat University Hospital, University Paris-Diderot Paris-7, Paris, France, <sup>4</sup>Department of Diabetes and Endocrinology, Centre Hospitalier Sud Francilien, Corbeil-Essonnes, France, <sup>5</sup>Department of Diabetes and Endocrinology, Centre Hospitalier Universitaire, Poitiers, France, <sup>6</sup>Department of Diabetes and Endocrinology, Hotel Dieu Hospital, <sup>7</sup>Unit of Transfer in Molecular Oncology and Hormonology, Saint-Louis University Hospital, University Paris-Diderot Paris-7, Paris, France, <sup>8</sup>INSERM U872, Centre de Recherche des Cordeliers, <sup>9</sup>Physiology, Pennington Biomedical Research Center, Baton Rouge, USA.

**Background and aims:** We previously reported that foetal exposure to maternal Type 1 Diabetes (T1D) is associated with kidney dysfunction at adult age, thereby conferring a potential risk for high blood pressure and renovascular diseases. The aim of the present work was to search for potential epigenetic modifications related to these anomalies.

**Materials and methods:** A total of 29 adult, non diabetic offspring of T1D mothers (case group) was compared with 29 non-diabetic offspring of T1D fathers (control group) for the methylation profile of their leukocyte DNAs (27,578 CpG sites, Human Methylation 27 BeadChip, Illumina Infinium®). A subset of 19 cases and 18 controls were studied for baseline and amino acid-stimulated Glomerular Filtration Rate (GFR), and Effective Renal Plasma Flow (ERPF), using a <sup>51</sup>Cr EDTA plus <sup>125</sup>I-hippurate primed constant infusion technique.

**Results:** Case and control groups were well matched for age (26±6 vs 26±6 yr), sex ratio (55 vs 52% women), fasting plasma glucose (4.5±0.4 vs 4.5±0.3 mM), body mass index (median 22.6 (range 17.9–29.9) vs 22.4 (19–27.7) kg/m<sup>2</sup>), and birth weight (3200 (2750–4270) vs 3300 (2700–4540) g). A total of 214 CpG sites were methylated differently in cases and in controls (p value set at ≤0.01). Global methylation of these 214 sites was 5% lower (95%CI 3.8 to 6.9 %, p<0.0001) in the case vs control groups with 190 sites less methylated and 24 sites more methylated in the case vs control group. The relationship between global methylation of these 214 sites and baseline GFR was significantly different between groups (p<0.05), with a positive correlation in the case group (r = 0.50, p = 0.036, i.e., the more methylation, the higher the baseline GFR) but not in the control group (r = -0.23, p = 0.37). A similar pattern of correlation was observed for amino acid-stimulated ERPF. The gene encoding DNA methyltransferase 1 (DNMT1), a key enzyme in maintaining methylation patterns during cell division, was one of the genes less methylated in exposed subjects.

**Conclusion:** Differences in methylation profile may impact kidney function of adult offspring of T1D mothers. However, these differences may act through pathways not specific to kidney development, or function.

### Transcriptomic analysis demonstrated a placental dysfunction during maternal diabetes

T. Bouckenooghe<sup>1</sup>, P. Perimenis<sup>1</sup>, E. Eury<sup>2</sup>, S. Lobbens<sup>2</sup>, G. Sisino<sup>1</sup>, P. Gosset<sup>3</sup>, J. Delplanque<sup>2</sup>, P. Fontaine<sup>4</sup>, L. Storme<sup>1</sup>, P. Froguel<sup>2</sup>, A. Vambergue<sup>1</sup>;

<sup>1</sup>EA4489, CHRU de Lille/Université Lille Nord de France, <sup>2</sup>UMR8199, Institut Pasteur de Lille/Université Lille Nord de France, <sup>3</sup>GHICL, Lille, France, <sup>4</sup>CHRU de Lille, France.

Nowadays, there is increasing evidence for a role of the perinatal environment in the metabolic programming of adult life. A disturbed intra uterine milieu, like maternal diabetes, can favor the occurrence of chronic diseases in adulthood. In animal models of streptozotocin (STZ) induced diabetes, few studies have assessed the potential role of the placenta and particularly the implication of feto-placental genes on fetal programming. In our work, we: 1) evaluate the consequences of maternal hyperglycemia on pups metabolism; 2) use systems biology approach to analyze differentially expressed placental genes to identify pathways involved in Intra Uterine Growth Retardation (IUGR) and in placental hypertrophy. We used 3 groups of animals:

DS (n=5, receiving 65 mg/kg of STZ at G7), D30 (n=9, receiving sequentially STZ & 75 mg/kg of Nicotinamide at G7) and a control group (n=9). We have evaluated metabolic parameters in mothers during gestation and in pups at birth. Placental whole genome expression was performed to identify genes differentially expressed between experimental groups (Illumina and qPCR for confirmation). Diabetes, in DS group is more pronounced than in D30 group. We have observed in our treated groups, an IUGR with placental hypertrophy. Histological observations showed a hypovascularization associated with an increase number of glycogen cells. These observations have been correlated with our transcriptomic analyses showing a modification of genes implicated in angiogenic and glycogen pathways. Especially, prolactin gene (Fold change>4) and protein were highly upregulated in the DS group partially explaining the hypovascularization that can be due to prolactin anti-angiogenic effect. To confirm this observation in human, we used placental samples collected from a cohort of patients with type 1 diabetes (cohort DIAMANT). As previously shown in our rat models, we observed an important increase in the placental expression of prolactin at mRNA (Fold change>18) and protein level in diabetic women. The two different models used in this study have shown an IUGR with placental hypertrophy. Maternal diabetes induces a profound modification of placental genes leading to a defect in angiogenesis. IUGR observed is the result of the placental hypovascularization and could profoundly modify the metabolic imprinting of the fetus.

## 82

### Lower levels of vitamin D at first trimester of pregnancy are associated with higher risk of developing gestational diabetes mellitus

M. Lacroix, M.-C. Battista, M. Doyon, M.-F. Hivert, P. Perron; Physiology/endocrinology, Sherbrooke's University, Canada.

**Background and aims:** Gestational diabetes mellitus (GDM) results from an imbalance between insulin resistance and insulin secretion capacity during pregnancy. Vitamin D (25OHD) is suspected to be implicated in mechanisms of insulin regulation. A few reports identified low 25OHD (<75 nmol/L) as a potential risk factor for the development of GDM. However, data are scarce and inconsistent, potentially because of uneven adjustment for confounding factors. We hypothesized that lower 25OHD levels at 1<sup>st</sup> trimester are associated with higher risk of developing GDM during pregnancy, after taking into account potential confounders.

**Materials and methods:** We recruited and followed prospectively a cohort of pregnant women representative of the general population delivering at our institution. At 1<sup>st</sup> trimester (between 6–13 weeks), we performed anthropometric measurements and blood samples. Women were excluded if they had diabetes prior pregnancy or diagnosed at 1<sup>st</sup> trimester. Levels of 25OHD were measured by Liquid Chromatography Tandem Mass Spectrometry (LC-MS/MS). At 2<sup>nd</sup> trimester, diagnosis of GDM was made based on a standard 75g oral glucose tolerance test, following International Diabetes Federation criteria.

**Results:** This analysis included 558 participants: 512 women with normal glucose tolerance (NGT) and 46 women who developed GDM (incidence rate of GDM = 8%). Mean level of 25OHD in our cohort was 62.0 ± 19.2 nmol/L. At 1<sup>st</sup> trimester, participants who developed GDM were older (NGT = 28.2 ± 4.3 years old; GDM = 30.5 ± 4.9 years old; p = 0.001), but had similar mean body mass index (BMI) (NGT = 25.1 ± 5.4 kg/m<sup>2</sup>; GDM = 27.3 ± 7.0 kg/m<sup>2</sup>; p = 0.06) and body fat percentage (BFP) (NGT = 31.0 ± 8.2 %; GDM = 33.9 ± 10.8 %; p = 0.08) compared to NGT participants. In univariate comparison analysis, 25OHD levels at 1<sup>st</sup> trimester tended to be higher in NGT women than in GDM women (NGT = 62.4 ± 19.4 nmol/L; GDM = 57.1 ± 16.6 nmol/L) but the difference was not statistically significant (p = 0.07). This trend was confirmed in simple logistic regression model predicting GDM incidence (OR = 1.30 per decrease of one SD in 25OHD levels; p = 0.09). However, after adjustment for major potential confounding factors (age, season of blood sampling and vitamin D supplement intake), lower 25OHD levels were significantly associated with higher risk of developing GDM (OR = 1.50 per decrease of one SD in 25OHD levels; p = 0.03). In addition, this association remained statistically significant after further adjustment for BMI (OR = 1.44; p = 0.046) or for BFP (OR = 1.43; p = 0.049).

**Conclusion:** Our results suggest that lower 25OHD levels at 1<sup>st</sup> trimester are associated with increased risk of developing GDM, after taking into consideration important confounding factors such as age, season of blood sampling, vitamin D supplementation and adiposity measurements, in a population-based cohort.

**The effect of real-time continuous glucose monitoring in diabetic pregnancy - a randomised controlled trial**A.L. Secher<sup>1,2</sup>, L. Ringholm<sup>1</sup>, H.U. Andersen<sup>3</sup>, P. Damm<sup>2,4</sup>, E.R. Mathiesen<sup>1,2</sup>;<sup>1</sup>Center for Pregnant Women with Diabetes, Department of Endocrinology, Rigshospitalet, <sup>2</sup>Faculty of Health Sciences, University of Copenhagen,<sup>3</sup>Steno Diabetes Center, <sup>4</sup>Center for Pregnant Women with Diabetes, Department of Obstetrics, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** Strict glycaemic control is the outermost crucial factor in reducing pregnancy complications in women with diabetes, but the effect of real-time continuous glucose monitoring (rt-CGM) in this population has not been thoroughly investigated before. The aim of this trial was to assess whether rt-CGM improves glycaemic control and pregnancy outcome in unselected women with pregestational diabetes.

**Materials and methods:** 123 women with type 1 diabetes and 31 women with type 2 diabetes were randomized to either intermittent use of rt-CGM for periods of up to six days at 8, 12, 21, 27 and 33 gestational weeks, in addition to routine care, or routine care only. HbA<sub>1c</sub>, self-monitored plasma glucose (SMPG), and severe hypoglycaemic events were registered. To optimize glycaemic control, rt-CGM data was evaluated with a diabetes caregiver. Pregnancy complications and outcomes were recorded, with macrosomia, defined as large for gestational age, as the primary outcome.

**Results:** Women assigned to rt-CGM (n=79) had similar duration of diabetes (median 10 (range 1-37) vs. 12 (1-38) years, p=0.38) and HbA<sub>1c</sub> at baseline (6.6 (5.3-10.0) vs. 6.8 (5.3-10.7) %, p=0.67) [49 (34-86) vs. 51 (34-93) mmol/mol] as women in the control arm (n=75). Rt-CGM was performed at least three times in pregnancy by 75% of the women. At 33 gestational weeks, HbA<sub>1c</sub> (6.1 (5.1-7.8) vs. 6.1 (4.8-8.2) %, p=0.40) [43 (32-62) vs. 43 (29-66) mmol/mol] and SMPG (6.2 (4.7-7.9) vs. 6.2 (4.9-7.9) mmol/l, p=0.64) were comparable regardless of rt-CGM use or not, and a similar fraction of women experienced severe hypoglycaemia (13 vs. 16%, p=0.55). The rates of macrosomia (43 vs. 30%, p=0.09) and other maternal-fetal outcomes were comparable between the groups.

**Conclusion:** In this randomized trial, intermittent use of rt-CGM in pregnancy did not improve glycaemic control or pregnancy outcome in women with pregestational diabetes.

## 84

**Pregnancy induced hypertensive disorder is related to HbA<sub>1c</sub>, BMI and weight gain in women with gestational diabetes**B. Barquiel Alcalá<sup>1</sup>, L. Herranz de la Morena<sup>1</sup>, I. Castro Dufoyny<sup>1</sup>, M.G. Llaro Casas<sup>1</sup>, P. Parra Ramírez<sup>1</sup>, M. Jáñez Furio<sup>2</sup>, L.F. Pallardo Sánchez<sup>1</sup>;<sup>1</sup>Diabetes Department, <sup>2</sup>Obstetrics Department, Hospital Universitario La Paz, Madrid, Spain.

**Background and aims:** Hypertensive disorder is linked to both gestational diabetes (GDM) and maternal pregestational overweight or obesity. Whether the severity of GDM seems to be related to this outcome, the influence of the glycaemic and weight evolution of the mother until the end of pregnancy is unknown. The aim of this study is to assess the relative influence of baseline carbohydrate intolerance, maternal pregestational weight and their changes on pregnancy hypertensive disorder in GDM women.

**Materials and methods:** 2568 GDM women were followed during the third pregnancy quarter in the Diabetes and Pregnancy Department from 1987 through 2008. Fasting glycaemia (FG) and area under the GDM diagnostic curve (AUC) (NDDG criteria) were considered as baseline glucose intolerance. Glycated haemoglobin A1c was monthly obtained as a glycaemic control parameter. Prepregnancy BMI (pre-BMI) was calculated on the basis of self-reported weight and the measured height. Weight gain ratio was defined as the quotient between total weight gain and the mean weight gain as suggested by the Institute of Medicine Guidelines for each woman's category of BMI. Univariate and adjusted multiple regression models were obtained. A p value under 0.05 was considered as statistical significance.

**Results:** The women's mean age was 32.9 ± 4.4 years old; 59 (2.5%) had chronic hypertension; median parity was 1 (IQ range 0-1); 458 (27.5%) were smokers in the group with the data available. Mean fasting glucose of the OGTT was 90.5 ± 14.6 mg/dl; mean HbA<sub>1c</sub> was 5.1 ± 0.4 %; mean prepregnancy BMI 24.75 ± 4.67 kg/m<sup>2</sup> and their median ratio of weight gain was 0.8 (IQ range 0.60-1.07). 175 (6.8%) women were diagnosed with gestational hypertension

(6.1 %) and/ or preeclampsia (0.7%). Univariate analysis showed an association of the hypertensive disorder with all the glycaemic and weight related parameters considered except for the AUC. Multivariate analysis showed that HbA<sub>1c</sub>, pre-BMI and weight gain ratio were independent predictors of the subsequent development of pregnancy hypertensive disorder when the data were controlled for age, chronic arterial hypertension, parity and urinary tract infection. The HbA<sub>1c</sub> excess risk [OR (95% CI)] was 1.69 (1.08-2.65) per unit increase, 1.19 (1.15-1.23) per BMI unitary increment and 1.58 (1.06-2.34) per increment of weight gain ratio. Attributable risk fractions were 40.8 (7.4-62.3)%, 16.0 (13.0-18.7)% and 36.7 (5.7-57.3)% respectively. The influence of glycaemic control and weight gain were enhanced after adjustment by tabaquism in a subgroup (n = 1664).

**Conclusion:** Gestational hypertensive disorder is predicted by evolutive HbA<sub>1c</sub>, which is a stronger predictor than OGTT FG or AUC. Excessive weight gain during pregnancy exerts an at least additive influence to pre-BMI. Indeed, gestational hypertensive disorders are independently related to HbA<sub>1c</sub>, BMI and a higher than recommended weight gain in women with gestational diabetes.

## OP 15 Role of the immune system in type 1 diabetes

### AntiGAD positivity: its prevalence and clinical impact in a large non-diabetic population: results from the HUNT study

E.P. Sørgjerd<sup>1</sup>, K. Midtthjell<sup>2</sup>, V. Grill<sup>1</sup>;

<sup>1</sup>Norwegian University of Science and Technology, Institute of cancer research and molecular medicine, Trondheim, <sup>2</sup>Norwegian University of Science and Technology, HUNT, Dept. of Public Health and general Practice, Levanger, Norway.

**Background and aims:** Development of autoimmune diabetes is strongly associated with autoantibody markers with high affinity towards the islet of Langerhans, such like Glutamic Acid Decarboxylase (antiGAD). Studies on the presence and clinical implications of antiGAD positivity in the general non-diabetic population are however few, especially in adults. We aimed to investigate these aspects prospectively in a large sample of non-diabetic adults from an all-population based cohort.

**Materials and methods:** The study was based on the second and third health surveys in Nord-Trøndelag county (HUNT2; 1996-98 and HUNT3; 2006-08) located in Norway. Altogether 37,059 adults > 20 years of age took part in both surveys, i.e. 40% of all adults in the county. Equal numbers of men and women (about 250 each) who were non-diabetic both at HUNT2 and 3, were randomly selected from different age groups (age 20-29, 30-34 etc. to 65+), to a total of 4496 individuals. AntiGAD was measured in serum from HUNT2 and cases positive for antiGAD were followed up 10-12 years later (HUNT3) by additional measurements of antiGAD. We also measured antiGAD in HUNT2 in 55 cases who had adult-onset autoimmune diabetes at HUNT3 but did not have diabetes in HUNT2. AntiGAD positivity was defined from cut-offs (>0.05ai) based on participation in the Diabetes Autoantibody Standardization Program, indicating 82% sensitivity and 99% specificity.

**Results:** In persistently non-diabetic individuals the prevalence of antiGAD positivity in HUNT2 was 1.69% (n=76). Prevalence was highest in the 30-34 (3.2 %, n=16) and 35-39 (2.4%, n=12) age groups. AntiGAD positivity was not associated with sex (n=40 men and n=36 women), first degree family history of diabetes (21% among negative vs. 21% among positive), smoking (25% vs. 23%), non-fasting glucose ( $5.2 \pm 0.92$  vs.  $5.2 \pm 0.78$  mmol/l, mean and SD) or BMI ( $26 \pm 4$  vs.  $26 \pm 3$  kg/m<sup>2</sup>). There was association with the presence of Thyroid Peroxide antibody positivity (p<0.025). AntiGAD positivity persisted at follow-up (HUNT3) in 35 out of 76 individuals (46%). Persistently non-diabetic subjects who were antiGAD positive at HUNT2 were compared with cases who were antiGAD positive and non-diabetic at HUNT2 but had diabetes at HUNT3 (n=34). The latter cases had higher frequency of first degree family history of diabetes (53% vs. 28%, p=0.01), had higher antiGAD titre both in HUNT2 (1.42 [0.07-1.98] vs. 0.08 [0.06-3.58], median [min-max], p<0.001) and HUNT3 (1.42 [0.07-1.98] vs. 0.08 [0.06-3.58], p<0.001), and higher non-fasting glucose both in HUNT2 ( $7.1 \pm 4.3$  vs.  $5.2 \pm 0.78$ , p=0.001) and HUNT3 ( $10.6 \pm 5.2$  vs.  $5.5 \pm 0.96$ , p<0.001) compared to those who did not develop diabetes.

**Conclusion:** AntiGAD positivity in long-term (10-12 years) non-diabetic individuals is partly consistent, is not associated with parameters related to diabetes, but associated with thyroid autoimmunity. AntiGAD positivity with later occurrence of diabetes is on the other hand associated with risk factors related to autoimmune diabetes.

### Thyroid function and autoimmunity in early pregnancy and risk of gestational diabetes mellitus: the mother-child RHEA cohort in Crete, Greece

L. Chatzi<sup>1</sup>, P. Karakosta<sup>1,2</sup>, D. Alegakis<sup>3</sup>, V. Georgiou<sup>1</sup>, E. Fthenou<sup>1</sup>, A. Pappas<sup>4</sup>, D. Boumpas<sup>3</sup>, E. Castanas<sup>2</sup>, M. Kogevas<sup>5</sup>;

<sup>1</sup>Faculty of Medicine, Department of Social Medicine, Heraklion, <sup>2</sup>Faculty of Medicine, Department of Experimental Endocrinology, Heraklion,

<sup>3</sup>Department of Rheumatology, Faculty of Medicine, Heraklion, <sup>4</sup>Diabetic Clinic, Venizelio Hospital, Heraklion, <sup>5</sup>National School of Public Health, Athens, Greece.

**Background and aims:** Maternal thyroid dysfunction, especially in early pregnancy, may lead to adverse obstetric and birth outcomes. The association between thyroid aberrations in early pregnancy and the development of gestational diabetes mellitus (GDM) remains little explored. The purpose of this study was to determine the extent to which, thyroid dysfunction and autoimmunity in early pregnancy is a risk factor for GDM.

**Materials and methods:** The study used data from the prospective mother-child cohort "Rhea" study in Crete, Greece, 2007-2009. The analysis included 1170 women with singleton pregnancies, and complete data on pregnancy outcomes. Maternal serum samples were collected at the time of the first major ultrasound (Mean: 12 weeks, SD: 1.5). Thyroid function was assessed by quantitative analysis of serum TSH (thyroid stimulating hormone), free thyroxine (free T4), free triiodothyronine (free T3), and thyroid peroxidase, and thyroglobulin antibodies (TPO-Ab and TG-Ab) [IMMULITE 2000 immunoassay system (Siemens Healthcare Diagnostics)]. Population-trimester-specific reference intervals were used to categorize women with low, normal, and high thyroid hormones during pregnancy. TPO-Ab and TG-Ab were considered elevated if levels were  $\geq 35$  IU/mL and  $>40$  IU/mL, respectively. Pregnant women were screened for gestational diabetes mellitus (GDM) between 24 and 28 weeks of gestation, and GDM was defined by the criteria proposed by Carpenter and Coustan. Multivariable log-poisson regression models were used to estimate the effect of thyroid function and autoimmunity in early pregnancy on the risk of GDM after adjusting for confounders.

**Results:** High TSH values were present in 79 (6.7%) women, while 29 (2.5%) women had low TSH. A total of 153 (13%) and 83 (7%) women had elevated levels of TPO-Ab and TG-Ab, respectively. Women with high TSH levels had a two fold higher risk of GDM (Relative Risk (RR) = 2.0, 95% CI = 1.0 - 4.0) after adjustment for maternal age, education, BMI before pregnancy, parity, family history of thyroid disease, and smoking during pregnancy. Stronger associations were estimated for the combination of high TSH levels and thyroid autoimmunity in early pregnancy and the risk of GDM (RR: 3.8, 95% CI = 1.7 - 8.5).

**Conclusion:** These findings suggest that women with high TSH levels and thyroid autoimmunity in early pregnancy had higher risk for GDM.

### Metabolic signals of seroconversion to islet autoantibodies in children at risk for type 1 diabetes

G. Kastenmüller<sup>1</sup>, J. Krumsiek<sup>1</sup>, M. Pflüger<sup>2,3</sup>, A. Ziegler<sup>2,3</sup>, M. Orešić<sup>4</sup>;

<sup>1</sup>Institute of Bioinformatics and Systems Biology, Helmholtz Zentrum München, Neuherberg, Germany, <sup>2</sup>Institute of Diabetes Research, Helmholtz Zentrum München, Neuherberg, Germany, <sup>3</sup>Forschergruppe Diabetes, Klinikum rechts der Isar, Technische Universität München, Germany, <sup>4</sup>VTT Technical Research Centre of Finland, Espoo, Finland.

**Background and aims:** Current high-throughput metabolomics techniques allow the assessment and quantification of hundreds of metabolites in human blood serum. Recently, the analysis of 29 amino acids and 12 lipid clusters revealed (age-dependent) metabolic differences between autoantibody-positive and -negative children at high risk for type 1 diabetes. The clusters had been determined based on 511 lipid-related traits whereof 290 so-called unknown metabolites are not assigned to a specific lipid molecule. The individual molecules have not been considered so far. In order to identify the molecules that most specifically indicate seroconversion and that may, thus, play an important role in autoimmunity, we revisited the data analyzing all 540 metabolic traits.

**Materials and methods:** For this study, we selected children, with a type 1 diabetic parent, who developed persistent islet autoantibodies (n=35), or

remained autoantibody-negative ( $n=35$ ), and were matched for age, date of birth, and HLA genotypes. UPLC-MS was used to quantify amino acids and lipids in the autoantibody-positive and the matched -negative serum samples. We applied Lasso logistic regression for discriminating between the autoantibody-positive and -negative group based on their metabolic profile. Moreover, we calculated a Gaussian Graphical Model (GGM) to embed the distinctive metabolites into their biochemical context. All individual metabolites and metabolite ratios that were significantly associated with the case/control phenotype based on a  $t$ -test were further characterized by testing their association to the genotypes of the subjects regarding single nucleotide polymorphisms (SNPs) at 12 type 1 diabetes risk loci.

**Results:** Interestingly, autoantibody-positive and -negative individuals can be perfectly distinguished by Lasso logistic regression based on the quantities of only five metabolites. This includes the triglyceride TG (44:1) and four unknown metabolites. The metabolite most relevant for the distinction of the two groups, namely an unknown metabolite with 310.2358  $m/z$ , showed largely different serum levels in autoantibody-positive ( $1.64 \pm 0.35 \mu\text{mol/l}$ ) and -negative ( $0.93 \pm 0.26 \mu\text{mol/l}$ ) individuals, making it a good candidate biomarker for seroconversion. For two of the four unknown metabolites, the GGM suggested a biochemical link to proline and tryptophan. Based on the important role of tryptophan catabolism in immunosuppression, we speculate that these unknowns might be involved in the regulation of tryptophan degradation. We further investigated the effect of genotypes at 12 diabetes risk loci onto the metabolite quantities in serum. Thereby, we revealed a possible link between various sphingomyelins and genetic variation in genes related to T cell receptor signaling (CTLA4, PTPN22). This includes a previously unknown metabolite that we identified and experimentally verified as the sphingomyelin SM (d18:2/22:0).

**Conclusion:** The detailed analysis of a metabolomics data set including unknown metabolites and the combination with genotyping data revealed novel molecular markers for the seroconversion to islet autoantibodies preceding type 1 diabetes.

### The type 1 diabetes-associated common polymorphism in IFIH1 may affect the likelihood of enterovirus viraemia

**O. Cinek<sup>1</sup>**, G. Tapia<sup>2</sup>, E. Witso<sup>2</sup>, L. Kramna<sup>1</sup>, K. Holkova<sup>1</sup>, T. Rasmussen<sup>2</sup>, L.C. Stene<sup>3</sup>, K.S. Ronningen<sup>3</sup>

<sup>1</sup>Department of Pediatrics, 2nd Faculty of Medicine, Charles University in Prague, Czech Republic, <sup>2</sup>Norwegian Institute of Public Health, Oslo, Norway, <sup>3</sup>Oslo University Hospital, Norway.

**Background and aims:** The rs1990760, a common single nucleotide polymorphism in the IFIH1 gene (encoding for interferon induced with helicase C domain 1) has been confirmed to modify the risk of type 1 diabetes (T1D). Its putative underlying mechanism involves sensing the double-stranded RNA during virus replication - this provides a potential link to enterovirus. We therefore investigated whether the rs1990760 polymorphism influences the rate of viraemia.

**Materials and methods:** Enterovirus RNA was tested in 1001 blood samples, each from an infant or toddler (taken at median age 12.3 months, IQR 9.2 - 13.5, 512 males / 489 females) recruited from the general Norwegian population in the MIDIA study (646 with the highest-risk HLA genotype for T1D, 355 with other HLA genotypes). The rs1990760 was in Hardy-Weinberg equilibrium, with frequencies of 15.7%, 48.5% and 35.8% for Ala/Ala, Ala/Thr and Thr/Thr genotypes, respectively. The viraemia was tested using qualitative nested real-time reverse transcriptase PCR on RNA extracted from frozen cell packs after removal of plasma. Stool samples collected along with the blood sample (in a time window spanning 30 days before to 15 days after the date of blood sample) were available in 417 of the individuals, having been previously analyzed for enterovirus using a quantitative real-time single-tube reverse-transcriptase PCR.

**Results:** Enterovirus RNA was present in 11.5% blood samples; the positivity rate depended on age (dropping steeply after the first year of age), on the calendar year, and marginally on the season. We then constructed a regression model having enterovirus viraemia as the outcome, with the IFIH1 genotypes and known modifiers (calendar year, age of the child) as the predictors. It suggested an influence of the IFIH1 946Ala/Thr heterozygosity (OR=2.2, 95%CI 1.1 - 4.2,  $p=0.023$ , relative to the Ala/Ala genotype), while the Thr/Thr homozygosity did not affect the risk of viraemia ( $p=0.42$ ). This effect remained unchanged in the model restricted to individuals who had the concomitant

stool samples tested for enterovirus (OR of the Ala/Thr 2.2,  $p=0.07$ ), and was apparently independent of the enterovirus positivity in the stool (enterovirus in the gut further increased the likelihood of viraemia, OR=2.2, 95%CI 1.3-3.9,  $p=0.007$ ).

**Conclusion:** We observed that the rs1990760 polymorphism, previously confirmed to be associated with the risk of T1D, may affect the likelihood of enterovirus viraemia; this effect is however not straightforward, as we detected a kind of 'molecular heterosis' (a larger effect of heterozygosity than of either homozygous genotype). Molecular heterosis has been repeatedly noticed in humans, so the association may be in line with the presumed function of IFIH1 in the T1D pathogenesis. Its role is further supported by the independence of the association from the enterovirus positivity in the concomitant stools.

### Detection of enteroviral protein expression and cellular antiviral responses in the islets of type 1 diabetes patients: a comparative analysis of two cohorts

**S.J. Richardson<sup>1</sup>**, A.J. Bone<sup>2</sup>, A.K. Foulis<sup>3</sup>, N.G. Morgan<sup>1</sup>

<sup>1</sup>Endocrine Pharmacology, Peninsula College of Medicine and Dentistry, Plymouth, <sup>2</sup>School of Pharmacy and Biomolecular Sciences, University of Brighton, Brighton, <sup>3</sup>Department of Pathology, Glasgow Royal Infirmary, UK.

**Background and aims:** Enteroviral infections have been implicated in the initiation of beta-cell destruction in human Type 1 diabetes (T1D) and the presence of both the enteroviral capsid protein, vp1 and the pathogen recognition receptor, protein kinase R (PKR) was demonstrated in serial islet sections from a UK cohort of recent-onset type 1 diabetic patients. A more-recently established cohort of longer duration type 1 diabetes cases (JDRF nPOD; USA) and non-diabetic controls were examined, to determine whether the islet endocrine cells also display evidence of enteroviral infection and a comparison made with the UK cohort.

**Materials and methods:** Formalin-fixed paraffin embedded pancreatic sections from nPOD cases (17 type 1 diabetes and 12 controls) were examined by immunohistochemistry for the presence of vp1 (Dako antibody; 5D8/1), insulin, PKR and class I MHC. Results were compared with those of a previously analysed UK cohort, consisting of 72 cases of recent-onset type 1 diabetes and 119 non-diabetic controls.

**Results:** Multiple intensely vp-1 positive islet cells were observed in many insulin-containing islets (ICI) in 8 of the 17 nPOD type 1 diabetes cases. Of the 9 remaining cases that did not stain positively for vp1, 7 were immunonegative for insulin (i.e. they were devoid of ICI). Hence, expression of vp1 was detected in the islet cells of 8 of the 10 nPOD cases (80%) with ICIs present. By contrast, only 4/12 (33%) non-diabetic nPOD controls showed evidence of vp1 positive islet cells and, even where these did occur, the absolute number of immunopositive cells was very low. Indeed, among the controls, we found only 1 case with a total of more than 5 vp1+ islet cells in the entire pancreas section. This compares with the type 1 diabetes cases where large numbers of vp1+ islets cells were observed both within individual islets and across multiple islets. Despite the concordance between the nPOD and UK cohorts, differences were noted when comparing pancreas samples recovered from organ donors and those obtained at autopsy. A marked increase was seen in the number of individual endocrine cells within any given islet that were immunopositive for vp1 among the organ donor samples ( $5.3 \pm 0.6\%$  vs  $1.8 \pm 0.3\%$ ;  $p<0.001$ ) and this was independent of the source of the material (whether from nPOD or the UK cohort). The results reveal that enteroviral infection occurs commonly in the  $\beta$ -cells in human type 1 diabetes in two entirely separate cohorts. Additional studies using immunofluorescence approaches revealed that expression of vp1 always correlated with increased PKR expression in the islets of both cohorts, and that vp1 and PKR were invariably present within the same individual beta-cells. This is consistent with the concept that enteroviral infection leads to the development of an anti-viral response in islet cells.

**Conclusion:** Enteroviral vp1 expression is observed at high frequency in the ICI of type 1 diabetes cases in both the nPOD collection and the (older) UK cohort. It appears that, regardless of disease duration the presence of viral proteins correlates with the presence of residual beta cells. In both cohorts, enteroviral vp1 expression correlated with increased expression of the pathogen-recognition receptor, PKR and with hyper-expression of class I MHC.

## 90

**Enterovirus genome and infectivity in peripheral blood leukocytes of children at the clinical onset of type 1 diabetes**A. Toniolo<sup>1</sup>, M. Colombo<sup>1</sup>, G. Bianchi<sup>1</sup>, A. Salvatori<sup>1</sup>, G. Federico<sup>2</sup>, A. Baj<sup>1</sup>;<sup>1</sup>Clinical and Experimental Medicine, University of Insubria Medical School, Varese, <sup>2</sup>Reproductive Medicine, University of Pisa Medical School, Italy.

**Background and aims:** Enterovirus (EV) infections are regarded as prominent environmental factors in the early stages of type 1 diabetes (T1D). On the day of clinical diagnosis of T1D, EV genome and infectivity were searched for in total peripheral blood leukocytes (PBL) of pediatric patients.

**Materials and methods:** This observational study was approved by the local Ethics Committee. PBL were obtained from 114 children on the day of T1D diagnosis at two Pediatric Endocrinology Centers in Italy (median age 9.0 yrs; range 2–16 yrs). EV-susceptible cell lines (RD, HeLa, AV3, CaCo) were co-cultured with the patients' PBL. Primers covering the 5' UTR, VP4, and 3D genome regions of EV of the A, B, C, and D species ( $\geq 100$  types) were used in highly sensitive RT-PCR assays that were run both on plasma and tissue culture medium from cell cultures exposed to patients' PBL. Expression of viral capsid proteins was evaluated in infected cell cultures using antiviral mAbs directed to the capsid protein VP1. Routine methods were used to measure levels of blood glucose, HbA1c, C-peptide (time 0 and 6 min after glucagon stimulation), diabetes related auto-Abs (GAD65, IA2, ZnT8, IAA), and - one year after diagnosis - the insulin requirement (IU/Kg/day). Immunoassays were used to quantify cytokines released by cultured cells. On the day of diagnosis, EV genome and infectivity were also searched for in consenting family members of 20 children.

**Results:** EV genome fragments and infectivity were detected in PBL of 90/114 (79%) children, versus 3/75 (4.0%) matched non-diabetic controls. Preliminary EV identification based on sequences of the 3Dpol genome region showed that EV of the B species were predominant (58% of positives). Viruses of the A, C, and D species were also detected. Tests on cell lines exposed to patients PBL confirmed the intracellular production of viral capsid antigen (immunofluorescence and WB). As compared to cell cultures exposed to controls' PBL, cell lines that had been exposed to patients' PBL released enhanced levels of the MCP1 chemokine. At the time of diagnosis, EV-positive patients had significantly higher levels of glucose and HbA1c as compared to EV-negative diabetic children. EV-positive children had also significantly reduced levels of glucagon-stimulated C-peptide. One year post-diagnosis, the insulin requirement was not different between the two groups. In a consenting cohort, EV genome and infectivity were found in blood of 18/20 (90%) diabetic children, 12/17 (70%) non-diabetic asymptomatic siblings, and 17/28 (61%) asymptomatic parents. Virus-positive members of each family shared the same EV species.

**Conclusion:** a) Detection of EV in blood represents a frequent biomarker of early stage T1D; b) EV of different species can be detected in newly-diagnosed patients (i.e., different EV species can associate with the early clinical stages of T1D); c) EV activity is expressed in human cell lines both as production of viral antigen and enhanced release of an inflammatory chemokine; d) EV genome and infectivity can be found both in newly diagnosed children and in their non-diabetic family members. This observation indicates that EV infections are spreading within the family at the early clinical stages of T1D. *Supported by:* CARIPO 2009-2577, VIDIS Group and Gianni Valcavi, Attorney

## OP 16 Mechanisms of insulin action

## 91

**Aerobic glycolysis is a major regulator of Akt activity**

S. Trefely, S. Tan, D.E. James;

Diabetes and Obesity, Garvan Institute of Medical Research, Sydney, Australia.

**Background and aims:** Tumour cells exhibit inordinately high levels of aerobic glycolysis, a phenomenon known as the Warburg effect. While the functional relevance of this effect is not known it is partly driven by upregulation of the enzyme PFKFB3 (6-Phospho-2-Fructo Kinase/Fructose-2,6-Bisphosphatase), which controls the synthesis of fructose-2,6-bisphosphate, an allosteric activator of glycolysis. Intriguingly, adipocytes exhibit the highest expression of PFKFB3 among most mammalian cell types. In view of the important role of the fat cell in nutrient sensing we wondered if PFKFB3 might play a role in this sensory mechanism. Consistent with previous studies we showed that fat cells apportioned the majority of their glucose uptake toward glycolysis. To test the role of PFKFB3 as a fuel sensor in adipocytes we examined the consequences of perturbing its activity and/or expression levels on glucose metabolism and insulin signalling.

**Materials and methods:** Insulin signalling was examined by immunoblot. Glucose uptake was measured using [<sup>3</sup>H]-2-deoxy-glucose. GLUT4 translocation was measured by cell surface labelling of HA-GLUT4 expressing cells. Lactate production was measured by extracellular flux analyser. The specific inhibitor of PFKFB3, 3PO (3-(3-pyridinyl)-1-(4-pyridinyl)-2-propen-1-one), was used to inhibit glycolysis. Overexpression of PFKFB3 and the bisphosphatase domain of PFKFB2 (BP-2) was used to increase or inhibit glycolysis, respectively. 3T3-L1 cells were electroporated with siRNA targeting the PFKFB3 sequence.

**Results:** Incubation of adipocytes with the PFKFB3 inhibitor 3PO led to a dose dependent decrease in insulin-stimulated glucose uptake and GLUT4 translocation. 100  $\mu$ M 3PO inhibited glucose uptake and GLUT4 translocation by 70% ( $p < 0.01$ ) and 50% ( $p < 0.01$ ) at sub-maximal dose (10  $\mu$ M). To further investigate the relationship between PFKFB3 activity and Akt signalling we examined the effect of over-expression or siRNA knock down of PFKFB3, or overexpression of the PFKFB3 antagonist BP-2, in HEK-293 cells. Knock down of PFKFB3 or BP-2 overexpression decreased insulin-stimulated Akt phosphorylation at Ser473 by 50% while PFKFB3 overexpression potentiated insulin-stimulated Akt phosphorylation increasing it 4 fold.

**Conclusion:** These studies reveal a novel mechanism for controlling Akt activity involving glucose flux via the glycolytic pathway. This pathway has potential implications for both cancer, where Akt activity may be driven by over stimulation of glycolysis, and diabetes where impaired glucose uptake may compromise Akt activity. The 'feedforward' mechanism by which insulin stimulation increases glycolysis is well described. Our study reveals a 'feedback' mechanism by which a defect in glycolysis decreases growth factor signalling through Akt.

## 92

**Upregulation of miRNA-143 expression by secretory products from epicardial adipose tissue from patients with type 2 diabetes abrogates insulin action in cardiomyocytes**M. Blumensatt<sup>1</sup>, S. Greulich<sup>1</sup>, B. Maxhera<sup>2</sup>, D. Herzfeld de Wiza<sup>1</sup>, P. Akhyari<sup>2</sup>, D.M. Ouwens<sup>1</sup>;<sup>1</sup>Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, <sup>2</sup>Department of Cardiovascular Surgery, Heinrich-Heine-University, Duesseldorf, Germany.

**Background and aims:** Cardiac dysfunction and myocardial insulin resistance are common in patients with type 2 diabetes. We have recently found that conditioned media (CM) generated from epicardial adipose tissue from patients with type 2 diabetes (CM-EAT-T2D) abrogate insulin action in primary rat cardiomyocytes. This was not observed in cardiomyocytes exposed to CM-EAT from patients without type 2 diabetes (CM-EAT-ND) and from subcutaneous (SAT) and pericardial adipose tissue (PAT) from the same patients. In this study, we examined whether the induction of insulin resistance can be ascribed to alterations in miRNA expression induced by CM-EAT-T2D.

**Materials and methods:** Biopsies from EAT, PAT and intrathoracic SAT were collected from males of Caucasian origin undergoing open heart surgery.

Participants were distributed into two groups, ND or T2D, on the basis of the diagnosis T2D in the patient's medical record. Conditioned media (CM) were generated from these biopsies from 7 different donors of each group. Primary adult rat cardiomyocytes were exposed to different CMs, and examined for alterations in the expression of 364 microRNAs by real-time PCR. The cardiac mouse cell line HL-1 was used for transfection with precursor-miRNAs to investigate the impact of miRNAs on insulin signalling. Effects on protein expression and phosphorylation were examined by Western blot analysis.

**Results:** Profiling miRNA expression in primary adult rat cardiomyocytes incubated with CM-EAT-T2D identified alterations in the expression of several miRNA species, including upregulation of let 7c (1.3 -fold), and the miRNA-143/145 cluster (1.4-fold), as compared to CM-EAT from patients without type 2 diabetes and CM generated from SAT and PAT from the same patients ( $P<0.05$ ). Validation of these miRNA species in HL-1 cardiomyocytes identified miRNA-143 as modulator of insulin action. Accordingly, transfection of HL-1 cardiomyocytes with a precursor of miR-143 (pre-miR-143) blunted the phosphorylation of Akt at Ser473 and Thr308 and its substrate proline-rich Akt substrate of 40-kDa (PRAS40) by insulin by 25% ( $P<0.05$ ). In addition, expression of pre-miR-143 reduced insulin-mediated GLUT4 translocation to the sarcolemma by 20% ( $P<0.05$ ), and insulin-mediated glucose uptake by 25% ( $P<0.05$ ). These effects were paralleled by a 20% reduction in protein levels of the miRNA-143 target and regulator of insulin action, the oxysterol binding protein-like 8 (ORP8) ( $P<0.05$ ).

**Conclusion:** Inhibition of insulin action in cardiomyocytes by secretory products from epicardial adipose tissue involves upregulation of miRNA-143. This miRNA inhibits the Akt-pathway regulating glucose uptake through downregulation of the novel regulator of insulin action, ORP8.

## 93

### Chronic carotid sinus nerve resection prevents the development of insulin resistance in rats fed with hypercaloric diets

M.J. Ribeiro, J.F. Sacramento, E.C. Monteiro, S.V. Conde;  
Farmacologia, CEDOC, Faculdade Ciências Médicas, Universidade Nova de Lisboa, Portugal.

**Background and aims:** The carotid bodies (CB) are peripheral chemoreceptors that respond to hypoxia by increasing the action potential frequency in their sensory nerve, the carotid sinus nerve (CSN), which increases minute ventilation and activates the sympathetic nervous system. Since increased sympathetic nervous system activity is a well-known pathophysiological mechanism for hypertension and insulin resistance (IR), herein we tested if blockade of CB activity through CSN resection prevents the development of IR in rats submitted to high fat (HF) and high sucrose (HSu) diets.

**Materials and methods:** Six groups of Wistar rats, aged 9–12 weeks were used. The control group was fed a sham diet (7.4% fat + 75% carbohydrate (4% sugar) + 17% protein); the HSu and HF models were obtained by the administration of 35% sucrose in drinking water during 28 days; or of a lipid rich diet (45% fat + 35% carbohydrate + 20% protein) during 21 days, respectively. Contribution of CB to the development of IR was assessed by submitting all the groups of animals to bilateral chronic CSN resection, 5 days prior to the beginning of the HF or HSu diet protocol. The control group was fed with regular chow and submitted to a sham surgical procedure. Surgical procedure was performed under the follow anaesthesia/recovery protocol: ketamine (30mg/kg) plus xilazine (4mg/kg) plus buprenorphine (10µg/kg). Experiments were performed at the end of the treatments under pentobarbital anaesthesia. Insulin sensitivity was measured through the insulin tolerance test (ITT). Blood pressure, weight, visceral and total fat, basal glycaemia, insulinemia, free fatty acids and corticosterone were also measured.

**Results:** Insulin sensitivity diminished in sham HF and HSu rats as the constant of the insulin tolerance test ( $K_{ITT}$ ) decreased significantly to  $2.82\pm0.32$  and  $2.23\pm0.29$  compared to the control value  $4.81\pm0.39$ . CSN resection in HF and HSu animals prevented the development of IR since  $K_{ITT}$  return to control values. Basal glycaemia was significantly increased in HSu but not in HF rats, and CSN resection restored the values to control levels. Insulinemia was significantly increased by 137.1% and 172.9% in HF and HSu rats, respectively and CSN resection completely abolished these increases. Non-esterified free fatty acids were increased in HSu animals and CSN denervation returns those values to control. Corticosterone levels were not modified by HF, HSu nor by bilateral CSN cut.

**Conclusion:** Our results suggest that CB is involved in the development of insulin resistance induced by hypercaloric diets.

### Resveratrol treatment restores peripheral insulin action in diabetic IRS2-deficient mice in a Sirt1-independent manner

Á. González-Rodríguez<sup>1,2</sup>, J.A. Mas-Gutiérrez<sup>3</sup>, V. Pardo<sup>1,2</sup>, E. Fernández-Millán<sup>1,4</sup>, A.I. Arroba<sup>1,2</sup>, B. Santamaría<sup>1,2</sup>, M.A. Mobasher<sup>1,2</sup>, C. Álvarez<sup>4,1</sup>, M. Ros<sup>3</sup>, Á.M. Valverde<sup>1,2</sup>;  
<sup>1</sup>CIBERDEM, <sup>2</sup>Instituto de Investigaciones Biomédicas “Alberto Sols” (CSIC/UAM), <sup>3</sup>Universidad Rey Juan Carlos, <sup>4</sup>Universidad Complutense, Madrid, Spain.

**Background and aims:** Mice with complete deletion of insulin receptor substrate (IRS) 2 develop hyperglycaemia, impaired hepatic insulin signalling and elevated gluconeogenesis. The elevated expression and activity of PTP1B in the liver of hyperglycaemic IRS2<sup>-/-</sup> mice block insulin receptor (IR)/IRS1-mediated insulin signalling by increasing the association of IR with this phosphatase. Accordingly, PTP1B inhibition by genetic (double mutant IRS2<sup>-/-</sup>-PTP1B<sup>-/-</sup>) and pharmacological (resveratrol treatment) strategies promotes insulin sensitivity in the liver of IRS2<sup>-/-</sup> mice through the restoration of IRS1-mediated Akt/Foxo1 phosphorylation and the inhibition of gluconeogenic enzymes. Moreover, resveratrol, a plant-derived polyphenolic compound, has been receiving increasing attention as a potent activator of the histone deacetylase Sirt1 with anti-oxidant and anti-neoplastic properties. In fact, recent studies have demonstrated that both resveratrol treatment and moderate increase of Sirt1 levels improved insulin sensitivity. On that basis, the purpose in this study was to investigate if resveratrol action on IRS2<sup>-/-</sup> mice is mediated by Sirt1 activation. For this goal, we have generated IRS2<sup>-/-</sup> mice with moderate over-expression of Sirt1.

**Materials and methods:** We characterized whole body glucose homeostasis, insulin sensitivity and insulin signalling in liver and muscle of hyperglycaemic IRS2<sup>-/-</sup> deficient mice, IRS2<sup>-/-</sup> mice treated with resveratrol (IRS2<sup>-/-</sup>-Resv) and IRS2<sup>-/-</sup> mice that moderate over-express Sirt1 (IRS2<sup>-/-</sup>-Sirt1). mRNA levels, protein expression and enzymatic activity of PTP1B in liver and muscle have been analyzed.

**Results:** Resveratrol treatment improved systemic insulin sensitivity in hyperglycaemic IRS2<sup>-/-</sup> mice but did not change glucose tolerance due to the inability to revert beta cell failure. On the other hand, moderate over-expression of Sirt1 in IRS2<sup>-/-</sup> mice did not recover neither peripheral insulin resistance nor glucose intolerance. In both liver and muscle of hyperglycaemic IRS2<sup>-/-</sup> mice levels of PTP1B were increased. Resveratrol treatment of IRS2<sup>-/-</sup> mice significantly decreased PTP1B mRNA and inhibited its activity in both tissues, thereby restoring IRS1-mediated PI3kinase/Akt signalling. Conversely, moderate over-expression of Sirt1 could not normalized PTP1B levels and, consequently, insulin signalling in liver and muscle remained impaired.

**Conclusion:** In conclusion, our results have established that elevated PTP1B expression in liver and muscle of hyperglycaemic IRS2<sup>-/-</sup> mice impaired insulin signalling. Accordingly, PTP1B inhibition by resveratrol promotes insulin sensitivity in IRS2<sup>-/-</sup> mice through the restoration of IRS1-mediated signalling in peripheral tissues. Moreover, we have demonstrated that the effects of resveratrol on insulin action in IRS2<sup>-/-</sup> mice are not mediated through Sirt1 activation.

### Local effects of cytokine TNF-alpha on glucose, protein and lipid metabolism in the placebo controlled bilaterally perfused human leg

E. Bosnjak<sup>1</sup>, R.R. Nielsen<sup>2</sup>, M. Buhl<sup>3</sup>, M.H. Vendelbo<sup>1</sup>, E. Tønhesen<sup>4</sup>, N. Møller<sup>1</sup>;

<sup>1</sup>Medical Department MEA, Aarhus University Hospital, NBG, Aarhus,

<sup>2</sup>Department of Cardiology, Aarhus University Hospital, Skejby,

<sup>3</sup>Department of Pediatrics, Aarhus University Hospital, Skejby, <sup>4</sup>Department of Anesthesia and Intensive Care Medicine, Aarhus University Hospital, NBG, Aarhus, Denmark.

**Background and aims:** Cytokine tumor necrosis factor alpha (TNF-alpha) has widespread metabolic actions, including induction of insulin resistance and cachexia. Systemic TNF-alpha administration, however, generates complex hormonal and metabolic scenario. No studies employing regional, placebo controlled TNF-alpha infusion exist. Our study was designed to test the hypothesis that local leg perfusion with TNF-alpha directly induces insulin resistance, lipolysis and protein breakdown.

**Materials and methods:** We studied eight healthy volunteers with bilateral femoral vein and artery catheters during 3-h basal period and 3-h insulin stimulation (hyperinsulinemic euglycemic clamp). One femoral artery was perfused with saline and the other with TNF- $\alpha$  (Tasonermin, 6 ng/kg/h). Amino acid metabolism was quantified with 15N-Phenylalanine tracer, lipid metabolism with 3H-Palmitate tracer and arterio-venous differences of free fatty acids and glucose metabolism was quantified by arterio-venous differences.

**Results:** TNF- $\alpha$  perfusion significantly (measured by Two Way RM ANOVA) increased local leg glucose uptake during the clamp. Basal glucose arterio-venous difference was unaltered, but substantially increased during the clamp ( $p<0.001$ ), with  $0.925\pm0.49$  mmol/l in the TNF- $\alpha$  leg, and  $0.744\pm0.43$  mmol/l in the placebo leg. Net phenylalanine release was increased by TNF- $\alpha$  perfusion ( $p=0.023$ ). During the basal period there was an increased phenylalanine release ( $p=0.003$ ), with  $4466\pm1390$   $\mu\text{g}/\text{min}$  in the TNF- $\alpha$  leg, and  $3794\pm1122$   $\mu\text{g}/\text{min}$  in the placebo leg, and an increased phenylalanine uptake ( $p=0.023$ ) with  $2951\pm1134$   $\mu\text{g}/\text{min}$  in the TNF- $\alpha$  leg, and  $2464\pm708$   $\mu\text{g}/\text{min}$  in the placebo leg. Free fatty acids and Palmitate kinetics were not affected by TNF- $\alpha$ .

**Conclusion:** TNF- $\alpha$  directly increased muscle protein breakdown and local muscle insulin sensitivity in terms of increased muscle glucose uptake. The finding of increased muscle loss may contribute to general protein loss during severe illness. The finding of increased insulin sensitivity is unexpected and highlights the necessity of differentiation between direct local cytokine effects as in this study and those secondary to release of stress cascades including hormones such as epinephrine, glucagon and cortisol.

### Thrifty metabolic responses to 36 hours of fasting in young men with low compared to normal birth weight

S.W. Jørgensen<sup>1,2</sup>, L.J. Bluck<sup>3</sup>, C. Brøns<sup>1</sup>, K. Færch<sup>3</sup>, A. Thankamony<sup>3</sup>, D. Dunger<sup>4</sup>, A. Vaag<sup>1</sup>

<sup>1</sup>Diabetes and Metabolism, Rigshospitalet, Copenhagen, <sup>2</sup>Steno Diabetes Center A/S, Gentofte, Denmark, <sup>3</sup>MRC Human Nutrition Research, Cambridge, UK, <sup>4</sup>Department of Paediatrics, University of Cambridge, UK.

**Background and aims:** The thrifty metabolic phenotype associated with low birth weight (LBW) imposes an increased risk of type 2 diabetes in an affluent society, but may conversely confer improved survival during sparse living conditions. We hypothesized that otherwise healthy individuals born with LBW may display an improved cardiometabolic risk profile when exposed to short time fasting compared with normal birth weight (NBW) controls.

**Materials and methods:** The participants were recruited from the Danish National Birth Register. LBW was defined as a birth weight  $\leq$  10th percentile and NBW between the 50th and the 75th percentile of the birth cohort. Eighteen NBW and 21 LBW young healthy male individuals, matched for age and BMI, were recruited and subjected to a 36-hour fast, followed by a frequently sampled intravenously glucose tolerance test (FS-IVGTT) to allow for minimal modelling. Glucose, insulin and lipids were collected frequently during the study. A [6,6-D<sub>2</sub>]-2H<sub>2</sub> glucose tracer was used to assess the rate of appearance of glucose (Ra) after 36 hours of fasting. [6,6-D<sub>2</sub>]-2H<sub>2</sub> glucose and insulin were included in the FS-IVGTT to assess glucose mediated glucose uptake (Sg) and insulin sensitivity (Si). Indirect calorimetry was obtained after 12, 31 and 34 hours of fasting.

**Results:** Serum insulin levels decreased significantly more in LBW compared with NBW subjects during the 36 hours fasting ( $p<0.001$ ). In addition, energy expenditure decreased in LBW subjects ( $P=0.11$ ) whereas it increased in NBW subjects during the fasting period ( $P=0.020$ ). LBW subjects displayed a lower fat oxidation rate than NBW subjects after fasting ( $P=0.015$ ). Rate of appearance of glucose (Ra) ( $P=0.046$ ) and glucose mediated glucose uptake (Sg) ( $P=0.054$ ) was lower in LBW compared with NBW subjects after fasting, whereas insulin sensitivity (Si) was not significantly different between groups. Plasma triglyceride levels decreased significantly more among LBW compared with NBW subjects after 36 hours of fasting ( $P<0.02$ ). After the IVGTT, excretion of glucose in the urine was disproportionately reduced in the LBW subjects ( $P=0.027$ ).

**Conclusion:** Young healthy men born with LBW displays a differential and more beneficial response of their cardiometabolic risk profile during 36 hours of fasting compared with those born with NBW. These results are consistent with the “thrifty phenotype hypothesis”, and the notion that LBW subjects are better to conserve energy during energy restricted conditions.

## OP 17 Mitochondria: signalling power plants of the beta cell

### 97

#### Deficiency of TFB1M leads to beta cell dysfunction and development of diabetes

V.V. Sharoyko, M. Ländin, I. Mollet, P. Spégel, L. Eliasson, N. Wierup, H. Mulder;

Clinical Sciences, Lund University, Malmö, Sweden.

**Background and aims:** Recently, we have used information from Genome-wide Association Studies of type 2 diabetes (T2D) and its associated traits, and identified a novel potential culprit in the pathogenesis of the disease: Transcription/translational Factor B1 Mitochondrial (TFB1M). This protein controls mitochondrial protein translation and therefore the expression of mitochondrially encoded genes. We observed that carriers of a common variant of *Tfb1m* are at increased risk of developing T2D, due to impaired insulin secretion and elevated glucose levels during an oral glucose tolerance test. Perturbed mitochondrial metabolism and impaired insulin secretion were found in *Tfb1m*<sup>-/-</sup> mice. To resolve the regulatory role of TFB1M in  $\beta$ -cells and its pathogenetic role in T2D islets, we performed *in vivo* and *in vitro* studies in a murine model of  $\beta$ -cell-specific *Tfb1m* deficiency ( $\beta$ -*Tfb1m*<sup>-/-</sup>).

**Materials and methods:** To create  $\beta$ -cell *Tfb1m*<sup>-/-</sup> mice, RIP-cre transgenic mice were cross-bred with floxed *Tfb1m*<sup>+/-</sup> mice.  $\beta$ -cell-specific knock out of TFB1M was assessed by qRT-PCR, primer extension analysis of 12S rRNA dimethylation. The OCR (oxygen consumption rate) was measured using the extracellular flux analyser XF24. ATP measured with a Luciferase-based luminescent assay. Ultrastructure analysis of insulin granules and mitochondria in  $\beta$ -cells within isolated islets was performed by electron microscopy. Monoclonal antibody MOMA-2 was used for immunocytochemical detection of macrophages in islets.

**Results:** The islets from *-Tfb1m*<sup>-/-</sup> mice were studied before onset of diabetes. Insulin secretion from islets in response to a rise from 2.8 to 16.7 mM glucose was significantly reduced compared to that in controls. *-Tfb1m*<sup>-/-</sup> islets showed an OCR rate at the basal glucose level and failed to increase their OCR in response to elevation of the glucose concentration. We also found a pronounced decrease in the rate of mitochondrial ATP production from *-Tfb1m*<sup>-/-</sup> islets compared to their controls. The volume density of insulin granules, which is a measure of the total number of granules, was reduced from  $10.7\pm0.7$  granules/ $\mu\text{m}^3$  in the control mice to  $4.7\pm1.1$  granules/ $\mu\text{m}^3$  in the  $\beta$ -*Tfb1m*<sup>-/-</sup> mice. The surface density of insulin granules, which is a measure of docked granules, was reduced from  $0.64\pm0.07$  granules/ $\mu\text{m}^3$  in the control mice to  $0.34\pm0.04$  granules/ $\mu\text{m}^3$  in the  $\beta$ -*Tfb1m*<sup>-/-</sup> mice. However, the fraction docked granules per total number of granules increased, why the reduction in docking is a consequence of the reduced number of granules. The granule diameter was  $317\pm7$  nm in control  $\beta$ -cells and  $385\pm9$  nm in the  $\beta$ -*Tfb1m*<sup>-/-</sup>  $\beta$ -cells. In the  $\beta$ -*Tfb1m*<sup>-/-</sup>  $\beta$ -cells area covered by mitochondria increased from  $7\pm2\%$  in the controls to  $19\pm9\%$  in the  $\beta$ -*Tfb1m*<sup>-/-</sup>. After 4 months of age, we found that virtually all  $\beta$ -*Tfb1m*<sup>-/-</sup> mice had developed diabetes and  $71\pm22\%$  of islets in  $\beta$ -*Tfb1m*<sup>-/-</sup> mice and  $32\pm8\%$  of islets in control mice were positive for macrophages.

**Conclusion:** Taken together our results obtained with the  $\beta$ -*Tfb1m*<sup>-/-</sup> mice suggest that *Tfb1m* deficiency plays a major role in  $\beta$ -cell function conferring to this protein, identified as a genetically associated T2D risk factor, a specific biological role in the pathogenesis of the disease. We suggest that the final effect on insulin secretion due to *Tfb1* deficiency may underline how perturbation in the mitochondrial proteome homeostasis is a condition which finally leads to the development of T2D. Further work will help in the validation of potentially new therapeutic targets.

**Fis1, a key regulator of the mitochondrial network, controls glucose responsiveness in beta cells**

J. Schultz<sup>1</sup>, A. Hempel<sup>1</sup>, R. Waterstradt<sup>1</sup>, A. Rieckmann<sup>1</sup>, V. Sharoyko<sup>2</sup>, H. Mulder<sup>2</sup>, M. Tiedge<sup>1</sup>, S. Baltrusch<sup>1</sup>;

<sup>1</sup>Institut of Medical Biochemistry and Molecular Biology, Rostock, Germany,

<sup>2</sup>Department of Clinical Sciences, Unit of Molecular Metabolism, Lund University Diabetes Centre, Malmö, Sweden.

**Background and aims:** Mitochondria exist in dynamic networks, and cycle continuously through fusion-fission events. Mitofusin 1 and 2 (Mfn1 and Mfn2) and the optic atrophy 1 protein (Opa1) are essential for mitochondrial fusion, whereas the fission protein 1 (Fis1) and the dynamin related protein 1 (Drp1) control fission. Because Fis1 determines the frequency of the fission process, this protein has been suggested to be a key regulator of mitochondrial dynamics. Moreover, impaired mitochondrial morphology in beta cells has been proposed to contribute to the pathogenesis of type 2 diabetes mellitus. Therefore, the aim of this study was to investigate mitochondrial dynamics in glucose-responsive and glucose-unresponsive INS1-derived beta cells with an emphasis on Fis1.

**Materials and methods:** Experiments were performed in INS1 832/13 (glucose-responsive) and INS1 832/2 (glucose-unresponsive) beta cells. Fis1 knockdown was evoked by the GIPZ lentiviral shRNAir system and Fis1 overexpression by transduction with the pLUX vector system. Lentiviral particles harbouring scrambled sequences served as control. Gene and protein expression were analyzed by quantitative real-time PCR, western blot and immunofluorescence analyses, respectively. ATP content was measured using the ATPlite assay and glucose-stimulated insulin secretion using ELISA. Mitochondrial morphology was determined after MitoTracker Green staining.

**Results:** In contrast to the efficient increase in the ATP concentration and insulin secretion in glucose-responsive cells, this response to a glucose stimulus was absent in glucose-unresponsive cells. Interestingly, in the glucose-unresponsive cells gene expression of Fis1, Drp1, Opa1, Mfn1 and Mfn2 was significantly reduced in comparison to glucose-responsive cells. Particularly the Fis1 protein level was significantly reduced in glucose-unresponsive cells. Consistent with the low Fis1 expression, we observed elongation and clustering of mitochondria in unresponsive cells. In contrast, glucose-responsive cells showed a homogenous mitochondrial network. To prove the hypothesis that Fis1 expression and the resulting mitochondrial structure significantly contribute to glucose responsiveness, Fis1 was knocked down in glucose-responsive cells. Indeed, we observed an elongation and clustering of mitochondria and a significant reduction of glucose-stimulated insulin secretion. We also demonstrated that overexpression of Fis1 in glucose-unresponsive cells improves the mitochondrial morphology and restores glucose-stimulated insulin secretion.

**Conclusion:** Our data suggest that the structure of the mitochondrial network in beta cells has an important impact on glucose-stimulated insulin secretion. We propose that Fis1 is a crucial factor in this process. Thus, the challenge of future studies will be the identification of regulators of Fis1 expression enabling selective counteraction of Fis1 down-regulation and loss of glucose responsiveness in beta cells.

**Activation of the 5-HT2b receptor in INS-1 cells couples to mitochondrial respiration and potentiates glucose stimulated insulin secretion**

H. Bennet, A. Balhuizen, V. Sharoyko, C.L. Nagorny, M. Fex;

The unit of diabetes and celiac disease, Clinical science, Malmö, Sweden.

**Background and aims:** 5-Hydroxytryptamine (5-HT) activates a large family of receptors. Several 5-HT receptors (5-HT1a, 5-HT2b and 5-HT1d) have previously been shown to be expressed in rodent islets of Langerhans. 5-HT has been shown to be present and co-secreted with insulin from rodent beta-cells. As both receptors and amines are present within the islets, 5-HT may potentially regulate hormone secretion from islets of Langerhans. A selective 5-HT2b agonist (alpha-Methyl serotonin maleate salt (alpha-MET)) potentiates glucose stimulated insulin secretion, but was unable to enhance the secretory response at low concentrations of glucose. Therefore, we hypothesize that 5-HT2b receptor signalling may affect glucose oxidation and consequently mitochondrial respiration.

**Materials and methods:** We used quantitative (Q) PCR to detect expression of the receptor in a beta-cell line (INS 832/13). One hour static incubations were performed in INS (832/13) cells using either low (2.8 mM) or high (16.7 mM) glucose with the addition of the selective 5-HT2b agonist alpha-MET (5uM). Knock down of the receptor in INS (832/13) cells was performed using siRNA and insulin secretion was measured using insulin ELISA. Oxygen consumption rate (OCR) was measured using the Seahorse extracellular flux analyser XF24 in a 24-well format by sensing changes in oxygen content in a 7 µl volume above the plated cells with a fluorescence biosensor.

**Results:** We found 5-HT2b to be expressed in INS (832/13) cells at the mRNA level. Moreover, stimulating the receptor using a specific agonist alpha-MET, at high glucose (16.7 mM) for 1 hour static incubations, potentiated glucose stimulated insulin secretion (P-value=0.002). In addition, performing knock-down experiments using siRNA resulted in a 70% decrease in expression at the mRNA level, and a 30% reduction in insulin glucose stimulated insulin secretion (P-Value=0.006). Preliminary data, performed in INS (832/13) cells, show that the overall OCR was increased with the addition of a high glucose. After adding FCCP, a wellknown uncoupler of the respiratory chain, alpha-MET provoked an increase in OCR, significantly higher than glucose alone, thereby indicating that alpha-MET can enhance overall oxidative capacity of the cells.

**Conclusion:** In this study we show that alpha-MET, via activation of the 5-HT2b receptor potentiates glucose stimulated insulin secretion. Subsequent knock down of the receptor diminishes glucose stimulated insulin secretion. Moreover, we show that 5-HT2b signalling enhance mitochondrial respiration. Therefore, our results strongly suggest that the 5-HT2b receptor signalling couples to mitochondrial respiration.

**Effects of catalase overexpression on insulin secretion, mitochondrial membrane potential and glucose-induced toxicity in insulin-secreting INS-1E cells**

S. Lortz, E. Gurgul-Convey, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

**Background and aims:** The expression of hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>) inactivating enzymes such as catalase in β-cells is extraordinary low and can explain their extreme susceptibility against reactive oxygen species (ROS) and proinflammatory cytokines. Whether this low expression pattern might be related to a signalling function of H<sub>2</sub>O<sub>2</sub> within the beta cell is unknown. A high expression level of H<sub>2</sub>O<sub>2</sub> inactivating enzymes could potentially be incompatible with glucose-stimulated insulin secretion (GSIS). In order to analyse the effect of catalase overexpression on mitochondrial function in insulin-secreting INS-1E cells effects on physiological insulin secretion were studied.

**Materials and methods:** The H<sub>2</sub>O<sub>2</sub>-inactivating enzyme catalase was overexpressed mitochondrially (MitoCat) or cytosolically (CytoCat) in insulin-secreting INS-1E cells. Successful overexpression was verified by measurement of catalase enzyme activity. The protective effect of catalase overexpression was quantified after cytokine treatment (IL-1β alone or a mixture of IL1β, TNF-α and IFN-γ) and hypoxic incubation. UCP2 expression was quantified by qRT-PCR, mitochondrial membrane potential was analysed with the fluorescence dye rhodamine 123, GSIS was measured after static glucose incubation (3, 10 and 30 mM) by RIA and the generation of ROS was detected by dichlorodihydrofluorescein diacetate (DCFDA-H<sub>2</sub>).

**Results:** The overexpression of catalase in both compartments resulted in a significant 14 - 17fold higher enzyme activity compared to controls. MitoCat overexpression protected INS-1E cells against cytokine- and hypoxia-mediated toxicity. Furthermore overexpression of MitoCat increased UCP2 expression significantly by 50 % while in CytoCat expressing INS-1E cells the UCP2 expression was unchanged. The mitochondrial membrane potential at 3 and 10 mM glucose was not affected by catalase overexpression, but at 30 mM MitoCat cells showed a significant reduction. Insulin secretion at 10 and 30 mM glucose was significantly higher compared with 0 mM and GSIS was not altered after catalase overexpression. Increasing glucose concentrations lead to a reduction of the ROS generation in control cells by 30 (10 mM) and 45 % (30 mM). At basal (3 mM) and elevated glucose concentrations (10 und 30 mM) MitoCat cells showed a 30 - 40% reduced ROS production.

**Conclusion:** The results suggest that the mitochondrial overexpression of catalase protects against proinflammatory cytokines and hypoxia. Although the expression of UCP2 was elevated in parallel, mitochondrial membrane potential and glucose-stimulated insulin secretion at physiological glu-

cose concentrations were not blunted, indicating that  $\text{H}_2\text{O}_2$  had no second messenger function for the insulin secretion signalling pathway and that a moderate uncoupling of the respiratory chain can be tolerated without loss of function. Elevated glucose concentrations did not result in a higher ROS generation rate, but instead in a reduction. The further reduction of the ROS generation by MitoCat and the missing effect of CytoCat overexpression indicate that the glucose-dependent ROS production is mitochondrially located. Therefore the mitochondrial catalase overexpression could protect pancreatic  $\beta$ -cells against cytokine-mediated  $\beta$ -cell destruction during autoimmune diabetes onset and after islet transplantation without interfering with physiological insulin secretion.

### The mitochondrial $\text{Ca}^{2+}$ uniporter MCU is essential for glucose and sulfonylurea sensing by mouse pancreatic beta cells

A.I. Tarasov<sup>1</sup>, F. Semplici<sup>1</sup>, M.A. Ravier<sup>2</sup>, E.A. Bellomo<sup>1</sup>, T.J. Pullen<sup>1</sup>, P. Gilon<sup>3</sup>, I. Sekler<sup>4</sup>, R. Rizzuto<sup>5</sup>, G.A. Rutter<sup>1</sup>;

<sup>1</sup>Department of Medicine, Imperial College London, UK, <sup>2</sup>Université Montpellier, France, <sup>3</sup>Université Catholique de Louvain, Brussels, Belgium,

<sup>4</sup>Department of Medicine, Ben Gurion University, Beer-Sheva, Israel,

<sup>5</sup>University of Padua, Italy.

**Background and aims:** Glucose induces insulin release from pancreatic  $\beta$ -cells by stimulating ATP synthesis, membrane depolarisation and  $\text{Ca}^{2+}$  influx. As well as activating ATP-consuming processes, cytosolic  $\text{Ca}^{2+}$  increases may also be transmitted into mitochondria to potentiate ATP synthesis. Whilst a candidate mitochondrial  $\text{Ca}^{2+}$  uniporter, MCU, encoded by *ccdc109a*, has recently been identified, its role in the pancreatic  $\beta$ -cell has yet to be explored. Here, we have silenced MCU in primary mouse  $\beta$ -cells and examined the role of this protein in mitochondrial  $\text{Ca}^{2+}$  transport, ATP synthesis and insulin secretion.

**Materials and methods:** We have combined patch-clamp electrophysiology with real-time imaging of compartmentalised changes in  $\text{Ca}^{2+}$  and ATP/ADP ratio in single primary mouse  $\beta$ -cells, using adenovirally-expressed recombinant targeted (Pericam, Perceval) or entrapped intracellular (Fura Red) probes. Insulin exocytosis was monitored in single cells with the extracellular membrane-bound  $\text{Zn}^{2+}$ -sensitive dye, ZIMIR. Expression of MCU was reduced through the use of lentivirally-delivered short-hairpin RNAs.

**Results:** Silencing of MCU resulted in a  $58 \pm 15\%$  ( $p < 0.05$ ) reduction of the depolarisation-induced mitochondrial  $\text{Ca}^{2+}$  increases but had no effect on cytosolic  $\text{Ca}^{2+}$  changes. In response to 16.7 mmol/l glucose, MCU-depleted cells displayed a normal first phase of cytosolic ATP/ADP ratio increase. However, the second (sustained) phase of ATP/ADP elevation showed  $42 \pm 8\%$  ( $p < 0.05$ ) inhibition in these cells. Finally, sulfonylurea-induced insulin secretion was markedly ( $67 \pm 17\%$ ,  $p < 0.02$ ) inhibited in the absence of MCU.

**Conclusion:** MCU is critical for mitochondrial  $\text{Ca}^{2+}$  uptake in pancreatic  $\beta$ -cells and thereby for the ability of these cells to respond to glucose with an appropriate activation of mitochondrial oxidative metabolism and ATP synthesis. Impaired insulin secretion in response to sulfonylureas suggests that mitochondrial  $\text{Ca}^{2+}$  increases may be required to facilitate the ATP-dependent delivery of insulin granules to the plasma membrane.

*Supported by: JDRF, Wellcome Trust*

**Results:** All  $\beta$ -cells showed stable Perceval fluorescence in the presence of 1 mM glucose. Elevation of the glucose concentration to 3, 5, 7 and 9 mM dose-dependently increased the fluorescence intensity to a stable level with superimposed oscillations in less than 20% of the cells. Further glucose elevation to 11 and 20 mM had no effect on the average Perceval fluorescence but dramatically increased the number of oscillating cells, reaching 95% at the highest concentration. However, the ATP sensor was not saturated under these conditions since addition of 10 mM L-glutamine caused a 39% further increase of Perceval fluorescence. Although the amplitudes of the Perceval oscillations were unaffected, the frequency increased from  $0.23 \pm 0.01 \text{ min}^{-1}$  at 11 mM to  $0.31 \pm 0.01 \text{ min}^{-1}$  at 20 mM glucose. The appearance of Perceval oscillations clearly depended on  $\text{Ca}^{2+}$ . When  $\text{Ca}^{2+}$  influx was prevented by diazoxide hyperpolarization, the  $\text{Ca}^{2+}$  channel inhibitor methoxyverapamil or removal of extracellular  $\text{Ca}^{2+}$ , Perceval fluorescence immediately increased to a stable level without oscillations.

**Conclusion:** Sub-plasma membrane ATP levels in  $\beta$ -cells increase with the glucose concentration in the 0–9 mM concentration range. Higher glucose concentrations favour the appearance of oscillations without affecting the average ATP level. The oscillations depend on elevation of the cytoplasmic  $\text{Ca}^{2+}$  concentration, which lowers the sub-membrane ATP levels. The dynamic interplay between ATP and  $\text{Ca}^{2+}$  is important for the generation of metabolic oscillations and pulsatile insulin secretion.

## 102

### Glucose-dependence of sub-plasma membrane ATP dynamics in pancreatic beta cells

J. Li, E. Gylfe, A. Tengholm;

Medical cell biology, Uppsala, Sweden.

**Background and aims:** ATP is an important messenger in  $\beta$ cell stimulus-secretion coupling by linking changes in glucose metabolism to electrical activity,  $\text{Ca}^{2+}$  signaling and insulin secretion. Measurements of oxygen consumption, NAD(P)H fluorescence and mitochondrial membrane potential indicate that the  $\beta$ cell metabolism oscillates. Yet there is little information about single-cell ATP dynamics and how glucose influences the ATP concentration of importance for insulin secretion in the sub-plasma membrane space.

**Materials and methods:** Islets from C57BL/6 mice were transduced with adenovirus expressing Perceval, an ATP sensor based on circularly permuted monomeric Venus fluorescent protein fused to the ATP-binding bacterial protein GlnK1. Fluorescence changes in the sub-plasma membrane space were recorded with total internal reflection fluorescence microscopy.

Hospital Düsseldorf, Düsseldorf, <sup>9</sup>Research Unit of Molecular Epidemiology,

Helmholtz Zentrum München, Neuherberg, <sup>10</sup>Hannover Unified Biobank,

Hannover Medical School, Hannover, Germany.

**Background and aims:** Biomarkers may lead to a better understanding of pathophysiological mechanisms in complex diseases. Gene expression profiles in various tissues are associated with type 2 diabetes in cross-sectional studies, but prospective transcriptomics studies for incident type 2 diabetes are lacking. The aim of this study was to identify biological pathways in which transcripts are enriched that are associated with incident type 2 diabetes.

**Materials and methods:** We investigated associations between genome-wide gene expression in peripheral blood and incident type 2 diabetes in 513 initially non-diabetic individuals within the population-based KORA S4/F4 cohort. During a follow-up of 7 years, 50 subjects developed type 2 diabetes. The association between mRNA transcripts and incident type 2 diabetes was assessed by logistic regression. We used Storey's critical values at a nominal false discovery rate of 0.1 for the correction for multiple testing. Gene-set enrichment analysis was performed using Ingenuity Pathway Analysis.

**Results:** After adjustment for age, sex and body mass index, 2,045 transcripts were found differentially expressed between incident cases and controls. Forty-three canonical pathways showed an enrichment of these differentially expressed transcripts. The strongest associations were observed for eIF2 (eukaryotic translation initiation factor-2) signalling, Benjamini-Hochberg adjusted  $P=2.93 \times 10^{-17}$ , eIF4/p70S6K (70-kDa ribosomal S6 kinase) signalling ( $P=9.19 \times 10^{-8}$ ) and mTOR (mammalian target of rapamycin) signalling ( $P=4.62 \times 10^{-7}$ ). We also found evidence ( $P$  between 0.05 and 0.0001) for an enrichment of differentially expressed transcripts and pathways involved in endoplasmic reticulum stress, inflammation, immune responses, lipid metabolism, endocrine function, mitochondrial function and cell/tumour proliferation and apoptosis.

**Conclusion:** In this first prospective transcriptomics study in incident type 2 diabetes we show that gene expression levels in peripheral blood are altered before the onset of type 2 diabetes and that differentially expressed transcripts are overrepresented in pathways related to cellular stress, regulation of protein synthesis and other processes which relate to insulin resistance.

#### MicroRNA expression fingerprint in serum of type 1 diabetic patients

G. Sebastiani<sup>1</sup>, I. Spagnuolo<sup>1</sup>, A. Patti<sup>1</sup>, F.A. Grieco<sup>1</sup>, D. Cataldo<sup>1</sup>, E. Ferretti<sup>2</sup>, C. Tiberti<sup>3</sup>, F. Dotta<sup>4</sup>;

<sup>1</sup>University of Siena and Umberto di Mario Foundation, <sup>2</sup>Dep. of

Experimental Medicine, University of Rome- Sapienza, <sup>3</sup>Dep. of Clinical

Sciences, University of Rome- Sapienza, Italy.

**Background and aims:** MicroRNAs (miRNAs) are a class of evolutionarily conserved small endogenous RNAs, 19–21 nucleotides long, which negatively regulate gene expression post-transcriptionally through their binding to the 3' untranslated region (3'UTR) of mRNA targets, thus affecting degradation and translation. MiRNAs are involved in many biological processes such as differentiation, cell cycle and apoptosis and their alterations have been observed in a number of pathological conditions, including autoimmune diseases. Recently,

it has been shown that miRNAs can be secreted by cells and their presence has been confirmed in many biological fluids including serum. In type 1 diabetes mellitus (T1D), the autoimmune process may be triggered years before clinical onset; indeed, it would be useful to identify novel and valid biomarkers for T1D prediction and follow-up, in addition to those already available (i.e. autoantibodies). Interestingly, a recent hypothesis focused on the possibility that circulating miRNAs may traffic from donor cells to distant sites and alter the gene expression of recipient cells. Indeed, any beta cell alterations of miRNA expression profile during T1D natural history may potentially affect the function(s) of cells receiving miRNA secreted from them. Consequently, the aim of our study was to look for a specific miRNAs fingerprint in T1D patient sera.

**Materials and methods:** To this end, we analyzed the expression profile of 384 miRNAs in serum of 20 newly-diagnosed T1D patients (age:  $31.3 \pm 10.8$  y) and 20 control subjects (age:  $32.2 \pm 8.3$  y), using stem-loop RT-PreAmp Real-time PCR and Taqman Low Density Array cards. All values were normalized using the external control ath-miR-159 and the endogenous controls snR-NAU6, miR-16 and miR-451. Array data was analyzed using the RQ Manager Software. Specific miRNAs expression data were subsequently validated using single assay RT Real Time PCR performed in duplicate.

**Results:** Among 384 miRNAs analyzed, 206 were detected in serum of the two groups, and among these, 64/206 were found differentially expressed between controls and newly-diagnosed T1D patients. Among these differentially expressed miRNA, we observed that 43/64 were downregulated and 21/64 upregulated compared to control subjects. By single assay RT Real-Time PCR, we confirmed that some miRNAs involved in immune processes (miR-155, miR-181a, miR-146a, miR-31, miR-199a) or involved in the regulation of the beta-cell function (miR-34a, miR-9), were indeed differentially expressed. Of note, we also observed that genes encoding for some differentially expressed miRNAs are located in the proximity of T1D genetic susceptibility regions (14q32.2 and 19p13.2) and therefore of particular interest.

**Conclusion:** In conclusion, these data demonstrate that some miRNAs are differentially expressed in newly-diagnosed T1D patients serum; Interestingly, some of these are involved in the regulation of immune response or of beta cell mass and function. Ongoing studies will further explore the role of these circulating miRNAs in order to establish whether they represent novel biomarkers for disease prediction and follow-up.

### 105

#### Epigenetic modifications in pancreatic islets from patients with type 2 diabetes

C.A. Ling<sup>1</sup>, T. Dayeh<sup>1</sup>, P. Volkov<sup>1</sup>, B. Yang<sup>1</sup>, A. Olsson<sup>1</sup>, E. Hall<sup>1</sup>, T. Rönn<sup>1</sup>, C. Wollheim<sup>2</sup>, M.D. Nitert<sup>3</sup>;

<sup>1</sup>Clinical Sciences, Lund University, Malmö, Sweden, <sup>2</sup>University Medical Center, Geneva, Switzerland, <sup>3</sup>University of Queensland, Brisbane, Australia.

**Background and aims:** Epigenetic factors, including DNA methylation and histone modifications, can help to explain how cells with identical DNA sequence can differentiate into different cell types with unique phenotypes. DNA methylation of CpG sites has been associated with transcriptional silencing. Recent studies from our group and others demonstrate that epigenetic modifications influence the pathogenesis of type 2 diabetes. We have shown that pancreatic islets from patients with type 2 diabetes exhibit increased DNA methylation and decreased expression of the insulin gene. Moreover, high levels of glucose increased DNA methylation of the insulin gene in clonal beta-cells. Other groups have shown that epigenetic modifications of *Pdx1* can decrease its expression and hence insulin secretion in rodent islets. The aim of the present study was to identify novel epigenetic modifications in pancreatic islets from patients with type 2 diabetes, using both a candidate gene approach and a genome-wide approach.

**Materials and methods:** DNA methylation was analyzed in human pancreatic islets from patients with type 2 diabetes and non-diabetic controls using both specific and genome-wide assays. These include EpiTYPER (Sequenom), Pyrosequencing (Qiagen) and the Infinium Human methylation 450k array (Illumina). DNA methylation was further related to islet gene expression and HbA1c levels.

**Results:** Pancreatic islets from patients with type 2 diabetes secrete less insulin in response to glucose in vitro compared with islets from non-diabetic donors ( $P < 0.05$ ). We identified individual CpG sites of the *PDX1* gene that exhibit increased DNA methylation in diabetic compared with non-diabetic human islets using a candidate gene approach ( $P = 8 \times 10^{-5}$ ). The degree of DNA methylation of these CpG sites correlated positively with HbA1c levels ( $\rho = 0.54$ ,  $P = 2.4 \times 10^{-5}$ ) and negatively with gene expression ( $\rho = -0.64$ ,  $P = 2.9 \times 10^{-5}$ ), suggesting that hyperglycaemia may increase DNA methylation

of *PDX1* in human islets. Using a genome-wide approach, a total of 3116 CpG sites were identified to be differentially methylated in pancreatic islets from patients with type 2 diabetes ( $Q < 0.05$  after a FDR analysis). Of these, 2988 CpG sites showed decreased and 128 CpG sites showed increased DNA methylation in islets from patients with type 2 diabetes. The identified CpG sites correspond to 1561 individual genes.

**Conclusion:** We have indentified genome-wide epigenetic modifications in pancreatic islets from patients with type 2 diabetes. Moreover, epigenetic modifications of *PDX1* were associated with reduced gene expression and impaired insulin secretion in human islets.

## 106

### Genome-wide methylation variations precede diagnosis of type 1 diabetes in children

N.A. West<sup>1</sup>, I.V. Yang<sup>2</sup>, T.E. Fingerlin<sup>1</sup>, G. Eisenbarth<sup>3</sup>, M. Rewers<sup>3</sup>, J.M. Norris<sup>1</sup>;

<sup>1</sup>Epidemiology, <sup>2</sup>Medicine, <sup>3</sup>Pediatrics, University of Colorado, Aurora, USA.

**Background and aims:** Epigenetic tagging of genes, such as DNA methylation, appears to be involved in autoimmune disease etiology. We aimed to interrogate the peripheral leukocyte genome for DNA methylation signatures associated with the development of type 1 diabetes (T1D).

**Materials and methods:** DNA was obtained prior to T1D diagnosis from 17 children younger than 10 years and from 17 age- and sex-matched non-diabetic, islet autoantibody negative controls followed by the Diabetes Autoimmunity Study in the Young (DAISY). Genome-wide DNA methylation profiles were determined using the comprehensive analysis of relative DNA methylation platform (CHARM) - a microarray-based method designed to examine 4.6 million CpG sites in the human genome using 2.1 million probes. Paired t-tests were used to identify differentially methylated CpG sites. A generalized moving average of p-values from hypothesis tests performed at each of the probes was calculated and corrected for false discovery rate.

**Results:** Using a pragmatic threshold of a corrected  $P < .05$ , we identified 16 differentially methylated regions (DMRs), associated with 16 genes, between cases and controls. Two of the identified genes, *SLC17A6* and *EIF4EBP2* (Table), have been associated with insulin and glucose regulation. *SLC17A6* encodes the glutamate transporter *VGLUT2*, which is expressed in both pancreatic  $\alpha$ - and  $\beta$ -cells and is involved in insulin and glucagon secretion, suggesting that this gene might play a significant role in diabetes pathogenesis. *EIF4EBP2* expression has been shown to be a component of the insulin signaling pathway with enhanced insulin signaling and increased glucose uptake as a consequence of reduced expression. Four of the identified genes have been specifically associated with development of T1D: *Siglec-15*, *RLTPR*, *SNTG1*, and *RXR $\alpha$*  (Table). Notably, the *SNTG1* gene has been associated with multiple sclerosis, a classical T cell-mediated autoimmune disease with a complex genetic background. Significant copy number variations within the *SNTG1* gene have also been reported between monozygotic twin pairs discordant for T1D. Further, differential DNA methylation within the *SNTG1* gene derived from purified CD14<sup>+</sup> monocytes was recently reported in a sample of T1D-discordant monozygotic pairs. The DMRs within the remaining genes (*GPR62*, *XKR4*, *FARP1*, *B4GALT3*, *PAQR9*, *ZNF679*, *MYL9*, *PTGFRN*, *LRRC4C*, and *OSBP*) have not been reported in T1D epigenome association studies. Thus, these regions may represent novel epigenetic risk loci for the disease.

**Conclusion:** Results from this study demonstrate different methylation patterns in T1D cases compared to age- and sex-matched controls in children with HLA-conferred genetic risk. Importantly, these patterns precede diagnosis of T1D in the cases, which suggest a possible etiologic role of T1D-associated epigenetic variation.

### Exercise induces altered DNA methylation in adipose tissue throughout the human genome

T.S. Rönn<sup>1</sup>, P. Volkov<sup>1</sup>, M. Dekker Nitert<sup>2</sup>, O. Hansson<sup>3</sup>, T. Elgzyri<sup>3</sup>, L. Groop<sup>3</sup>, K.-F. Eriksson<sup>4</sup>, C. Ling<sup>1</sup>;

<sup>1</sup>Clinical Sciences, Malmö, Epigenetics & Diabetes, Malmö, Sweden, <sup>2</sup>Royal Brisbane Clinical School, Herston, Australia, <sup>3</sup>Diabetes & Endocrinology, Malmö, <sup>4</sup>Vascular Diseases, Malmö, Sweden.

**Background and aims:** A sedentary lifestyle and poor diet makes obesity a growing health problem. Obesity is also a predictor for type 2 diabetes (T2D), which suggests a central role for adipose tissue in the pathogenesis of T2D, in combination with genetic and life-style factors. Physical exercise is important for weight maintenance, but also for improved insulin sensitivity. Recent studies point towards epigenetic changes to be involved in the regulation of genes important for glucose metabolism and the pathogenesis of T2D. Here we study genome-wide changes in DNA methylation in subcutaneous fat after an exercise intervention study, in healthy, but previously sedentary men.

**Materials and methods:** This study included 31 men from Malmö, Sweden, participating in a six months supervised exercise intervention study. At inclusion they were all sedentary but healthy, with a mean age of 37.4 years and a mean BMI of 27.8 kg/m<sup>2</sup>. Subcutaneous fat biopsies were obtained before and after the intervention, followed by DNA and RNA extraction. DNA methylation was analysed using Infinium HumanMethylation450 BeadChip assay (Illumina), covering 485577 CpG sites from 21231 genes. RNA microarray analysis was performed using GeneChip® Human Gene 1.0 ST array (Affymetrix).

**Results:** Complete DNA methylation data was obtained from 23 individuals both before and after the exercise intervention, including a total of 476753 probes after quality control. The average methylation was high in regions 200 bp upstream of transcription start site (TSS), in 5' untranslated regions (UTR) and in the first exon, and they all significantly increased after exercise ( $q \leq 0.01$ ). The average level of DNA methylation was low in regions 1500-200 bp upstream of TSS, within the gene body, in 3' UTRs and in intergenic regions, and did not show an overall change with exercise. Applying FDR correction ( $q < 0.05$ ) resulted in 17975 probes significantly different after exercise compared with baseline. We further filtered our results requiring the average change in DNA methylation ( $\beta$ -value) for each probe to be  $\geq 5\%$  between groups, which resulted in 1009 significant individual probes, 911 increasing and 98 decreasing, after the six months exercise intervention. Of these, 723 probes are located in relation to one or more genes, and correspond to 641 unique genes. One example is found in *ITPR2*, a locus reported to be associated with waist-hip ratio. Individual CpG-sites with a difference in methylation after versus before exercise ( $q < 0.05$  and difference in mean  $\beta$ -values  $\geq 5\%$ ) was matched with probe sets that changed in mRNA expression after exercise ( $q < 0.05$ ). Gene regions including 249 significant DNA methylation probes were found to also have a significant change in mRNA expression after exercise. Of these, 155 probes showed an inverse relation to mRNA expression. 151 probes showed an increase in DNA methylation and a corresponding decrease in gene expression, while only 4 probes decreased the level of DNA methylation together with increased gene expression.

**Conclusion:** We have shown a general increase in DNA methylation in human adipose tissue in response to long-term exercise, but also a change in DNA methylation on the level of individual probes and genes. Interestingly, 34% of the significant probes within gene regions also showed a difference in mRNA expression of that gene.

**Early metabolic markers of the development of dysglycaemia and type 2 diabetes and their physiological significance**

E. Ferrannini<sup>1</sup>, A. Natali<sup>2</sup>, S. Camastra<sup>3</sup>, M. Nannipieri<sup>3</sup>, A. Mari<sup>4</sup>, K.-P. Adam<sup>5</sup>, M. Milburn<sup>5</sup>, G. Kastenmuller<sup>6</sup>, J. Adamski<sup>7</sup>, T. Tuomi<sup>8</sup>, V. Lyssenko<sup>9</sup>, L. Groop<sup>9</sup>, W. Gall<sup>10</sup>, RISC Study Group;

<sup>1</sup>Internal Medicine, University of Pisa, Italy, <sup>2</sup>Clinical and Experimental Medicine, University of Pisa, Italy, <sup>3</sup>Medicine, University of Pisa, Italy, <sup>4</sup>Institute of Biomedical Engineering, National Research Council, Padova, Italy, <sup>5</sup>Metabolon, Inc., Durham, NC, USA, <sup>6</sup>Institute of Bioinformatics and Systems Biology, Helmholtz Zentrum München, Neuherberg, Germany, <sup>7</sup>Institute of Experimental Genetics, Helmholtz Zentrum München, Neuherberg, Germany, <sup>8</sup>Medicine, University of Helsinki, Finland, <sup>9</sup>Department of Clinical Sciences, Diabetes, and Endocrinology, Lund University, Malmö, Sweden, <sup>10</sup>Diagnostics, Metabolon, Inc., Durham, USA.

**Background and aims:** Metabolomic screening of fasting plasma from non-diabetic subjects identified alpha-hydroxybutyrate (AHB) and linoleoyl-glycerophosphocholine (L-GPC) as joint markers of insulin resistance (IR) and glucose intolerance. We tested their predictivity for incident dysglycemia and investigated their potential physiological role.

**Materials and methods:** Metabolite profiling was carried out in 1,261 non-diabetic participants of the RISC study and 2,580 subjects of the Botnia cohort. Three-year (RISC) and 9.5-year (Botnia) follow-up data were analyzed.

**Results:** In both RISC and Botnia baseline data, AHB was a positive correlate, and L-GPC a negative correlate, of insulin sensitivity; AHB was also reciprocally related to indices of beta cell function. In a subgroup of Botnia subjects, higher AHB was associated with higher branched-chain amino acid and free fatty acid levels, and decreased glycine (constituent of glutathione). In follow-up, AHB was a positive predictor (adjusted odds ratios 1.25 [95%CI:1.00-1.60] and 1.26 [95%CI:1.07-1.48], respectively) and L-GPC a negative predictor (adj. odds ratios 0.64 [95%CI:0.48-0.85] and 0.67 [95%CI: 0.54-0.84]) of dysglycemia (RISC) or type 2 diabetes (Botnia), independent of familial diabetes, sex, age, BMI, and fasting plasma glucose, with ROC area-under-curves of 0.791 and 0.783. In morbidly obese subjects undergoing bariatric surgery, AHB halved (6.14[3.64] to 3.47[1.43] microg/ml,  $p < 0.0001$ ) as insulin sensitivity doubled (19.9[17.4] to 41.4[10.5] micromol·min<sup>-1</sup>·kg<sub>ffm</sub><sup>-1</sup>,  $p < 0.0001$ ). Consistent with their association with insulin sensitivity and secretion, in INS-1E cell cultures, AHB inhibited and L-GPC stimulated glucose/arginine-induced insulin release at physiological concentrations.

**Conclusion:** AHB and L-GPC are early independent predictors of worsening glucose tolerance in diverse populations. Physiologically, AHB and L-GPC appear to be signatures of IR, beta cell dysfunction, and metabolic overload.

## OP 19 Novel therapies

## 109

**Optimising Phase 3 dose selection with ITCA 650: correlation between baseline HbA<sub>1c</sub> and reduction of HbA<sub>1c</sub> after 24 weeks of treatment**

R.R. Henry<sup>1</sup>, J. Rosenstock<sup>2</sup>, T. Alessi<sup>3</sup>, K. Luskey<sup>3</sup>, M. Baron<sup>3</sup>;

<sup>1</sup>University of California, San Diego, La Jolla, <sup>2</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, <sup>3</sup>Intarcia Therapeutics, Inc., Hayward, USA.

**Background and aims:** Current therapy with exenatide requires frequent injections and is associated with significant nausea, often leading to poor patient (pt) adherence with therapy that may compromise clinical outcomes. ITCA 650 is an injection-free form of exenatide therapy that provides continuous subcutaneous delivery for 3, 6 or 12 months from a single placement. Subcutaneous delivery of a stable daily dose of exenatide is expected to allow plasma levels to consistently reside within a predictable therapeutic window, thus providing effective glycemic control while mitigating side effects associated with variable exenatide plasma levels and ensuring pt adherence. ITCA 650 was evaluated in a 24-week phase 2 study to select the optimal dosing regimen for evaluation in phase 3 studies.

**Materials and methods:** Pts with type 2 diabetes (T2DM) (n=155) and mean baseline HbA<sub>1c</sub> of 8.0% were randomized to receive ITCA 650 20 mcg (n=51), or 40 mcg (n=51) or twice-daily injectable exenatide (5mcg titrated to 10mcg) (n=53) for a duration of 12 weeks (wks). After 12 wks, pts receiving ITCA 650 were re-randomized to continue treatment at their original dose or to increase to a higher dose: half of pts originally randomized to 20 mcg increased to 60 mcg, half of those receiving 40 mcg increased to 80 mcg and pts randomized to exenatide injections were assigned 1:1 to receive ITCA 650 40 mcg or 60 mcg. Therefore, approximately two-thirds of pts received ITCA 650 40 or 60 mcg during wks 13- 24 with the option to continue at that dose through wk 48.

**Results:** Overall, chronic administration of the higher doses of ITCA 650 (40, 60 and 80 mcg) had greater effects on reducing HbA<sub>1c</sub>, FPG, PPG and body weight compared to 20 mcg. The 40 and 60 mcg doses of ITCA 650 were better tolerated than 80 mcg. Further evaluation by baseline HbA<sub>1c</sub> revealed that substantially greater reductions in HbA<sub>1c</sub> were achieved in pts with higher baseline HbA<sub>1c</sub> treated with 60 mcg compared to 40 mcg (Table). Target HbA<sub>1c</sub> < 7.0% was achieved in 60% of pts treated with 60 mcg whose baseline HbA<sub>1c</sub> was > 8.0% with 44% achieving HbA<sub>1c</sub> ≤ 6.5%. By comparison 29% of pts on 40 mcg achieved HbA<sub>1c</sub> < 7.0% and none achieved ≤ 6.5%.

**Conclusion:** Based on recommended target goals to maintain HbA<sub>1c</sub> levels < 7.0% or ≤ 6.5%, this additional analysis of the ITCA 650 phase 2 study population by baseline HbA<sub>1c</sub> in combination with previously reported favorable tolerability and quality of life (QoL) profiles enhance the assessment of benefit risk and support the selection of a chronic dose of 60 mcg for phase 3 evaluation of ITCA 650.

Table 1 Change in HbA<sub>1c</sub> from Baseline and Proportion of Patients Reaching HbA<sub>1c</sub> Targets by Baseline

ITCA 650		HbA <sub>1c</sub> Change from Baseline			
Chronic Dose	n=	All	Baseline >7.0%	Baseline > 7.5%	Baseline > 8.0%
40 mcg/day	41	-0.86	-0.87	-0.90	-0.72
60 mcg/day	42	-1.38	-1.49	-1.77	-2.22
ITCA 650		Percentage of Patients with HbA <sub>1c</sub> < 7.0 at Week 24 by Baseline			
Chronic Dose	n=	All	Baseline >7.0%	Baseline > 7.5%	Baseline > 8.0%
40 mcg/day	41	69.0%	65.8%	55.6%	28.6%
60 mcg/day	42	70.7%	66.7%	63.0%	61.1%
ITCA 650		Percentage of Patients with HbA <sub>1c</sub> ≤ 6.5 at Week 24 by Baseline			
Chronic Dose	n=	All	Baseline >7.0%	Baseline > 7.5%	Baseline > 8.0%
40 mcg/day	41	33.3%	28.9%	18.5%	0.0%
60 mcg/day	42	48.8%	44.4%	40.7%	44.4%

## 110

**Effect of MK-3102, a novel once-weekly DPP-4 inhibitor, over 12 weeks in patients with type 2 diabetes mellitus**

I. Gantz, M. Chen, A. Mirza, S. Suryawanshi, M.J. Davies, B.J. Goldstein; Merck Sharp & Dohme Corp., Whitehouse Station, USA.

**Background and aims:** MK-3102 is a potent, oral, once-weekly, dipeptidyl peptidase-4 (DPP-4) inhibitor in development for the treatment of type 2 diabetes mellitus (T2DM). The convenience of an effective, well-tolerated, weekly oral drug has the potential to improve medication adherence and may translate into better long-term outcomes. The present study evaluated the 12-week efficacy and safety of MK-3102 monotherapy in patients with T2DM.

**Methods:** MK-3102 monotherapy was evaluated in a randomised, double-blind, placebo (PBO)-controlled, dose-range finding study. After a diet/exercise run-in and, for patients on an antihyperglycaemic agent, a drug wash-off period, eligible patients (N = 685) were randomised equally to one of six once-weekly (q.w.) treatments: PBO or MK-3102 0.25, 1, 3, 10, or 25 mg for 12 weeks. The primary efficacy endpoint was the change in HbA<sub>1c</sub> from baseline at Week 12. The analysis was based on a step-down trend test using a longitudinal model assuming the same baseline HbA<sub>1c</sub> with terms for treatment, prior antihyperglycaemic therapy status, geographic region, and the interaction of time by treatment and time by prior antihyperglycaemic therapy status.

**Results:** At baseline, randomised patients (56% males) had a mean HbA<sub>1c</sub> of 8.1%, mean fasting plasma glucose (FPG) of 9.5 mmol/L, and mean duration of diabetes of 5.4 years. At Week 12, MK-3102 significantly reduced HbA<sub>1c</sub> by 0.28% to 0.71% from baseline relative to PBO in a dose-dependent manner (Table). PBO-adjusted changes from baseline in 2-hour postmeal glucose (PMG) were significant at all doses and ranged from 1.0 to 2.5 mmol/L. Relative to PBO, FPG was significantly reduced from baseline with MK-3102 doses above 0.25 mg q.w. Treatment with MK-3102 was associated with a low incidence of hypoglycaemia (0 to 2%) that was similar to PBO (1%).

**Conclusion:** Treatment with once-weekly MK-3102 monotherapy improved glycaemic control and was generally well tolerated over 12 weeks in patients with T2DM.

## 111

**KRP-104, a DPP-4 inhibitor that uniquely matches extracellular target localisation with compound exposure, is a safe and effective candidate for type 2 diabetes**

T. Ide<sup>1</sup>, W. Hori<sup>2</sup>, J.S. Rosenblum<sup>3</sup>, L. Minimo<sup>3</sup>, T. Matsui<sup>1</sup>, Y. Kitamura<sup>1</sup>, T. Anraku<sup>2</sup>, K. Shimamoto<sup>2</sup>, M. Yamasaki<sup>2</sup>

<sup>1</sup>Discovery Research Laboratories, Kyorin Pharmaceutical Co., Ltd., Tochigi, Japan, <sup>2</sup>Development Research Laboratories, Kyorin Pharmaceutical Co., Ltd., Tochigi, Japan, <sup>3</sup>ActivX Biosciences, Inc., La Jolla, USA.

**Background and aims:** Dipeptidyl peptidase (DPP) IV is a validated drug target for diabetes. In general, selectivity is required for enzyme inhibitors to avoid adverse effects. *In vivo* selectivity is mainly determined by enzyme inhibition potency and drug concentration in relevant tissues. DPP-4 exists as both a membrane-anchored cell-surface protein and in the circulation. Therefore, there is no benefit to intracellular access for a DPP-4 inhibitor. Indeed, intracellular access for such compounds could be a serious liability. Here we show the unique pharmacodynamic, pharmacological and toxicological profile of KRP-104, a DPP-4 inhibitor that results in nearly exclusive extracellular compound exposure *in vivo*.

**Materials and methods:** Cell-free enzyme inhibition of KRP-104 and its metabolite GIS-103 were determined using substrate-based assays of human DPP-4-related enzymes. Cell permeability of GIS-103 was determined

by activity-based profiling of DPP-4 inhibition in intact cells treated with the compound. Tissue distribution studies of DPP-4 inhibitors were performed after single oral administration in rats.

**Results:** KRP-104 was rapidly converted *in vivo* into an active metabolite GIS-103. GIS-103 was a potent DPP-4 inhibitor (IC<sub>50</sub>: 3.4 nM) selective for DPP-4 over the related enzymes DPP-8 and DPP-9 (150-fold for DPP-8, 82-fold for DPP-9), completely inactive on cytosolic DPP-9 in cells treated with 20 μM compound (Fig.). GIS-103 was distributed almost exclusively to the extracellular compartment at therapeutic doses, due to low cellular membrane permeability at clinically relevant inhibitor concentrations. Furthermore, after a single oral dose of 10 mg/kg KRP-104 to fasted rats, the concentrations of GIS-103 in tissues were far lower than that of GIS-103 in plasma. In contrast, the DPP-4 inhibitors sitagliptin and vildagliptin were present in tissues at equal or even much higher concentrations than in plasma. GIS-103 stayed in the target organ (blood stream) and did not distribute to irrelevant tissues. Following oral administration to mice, KRP-104 and GIS-103 caused a dose related inhibition of plasma DPP-4 activity and a significant decrease in plasma glucose levels after oral glucose challenge. ICH-compliant toxicology programs and a 52-wk repeat-dose toxicity study in cynomolgus monkeys supported favorable safety profile.

**Conclusion:** The biological profile of KRP-104 is differentiated from other DPP-4 inhibitors and is characterized by *in vivo* selectivity. The combination of high selectivity for DPP-4, rapid and extensive conversion to GIS-103 *in vivo* after absorption, and extracellular distribution of GIS-103 may provide an advantage in avoiding adverse effects during long-term therapy for type 2 diabetes.

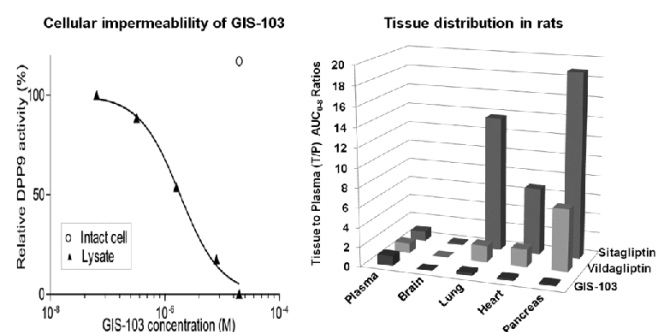

Fig. Cellular impermeability of GIS-103: intact HEK293 cells were treated with 20 μM GIS-103 concentration (circle). Following a 1 hour incubation, cells were washed, lysed and labeled with a serine hydrolase probe (AX7890). In parallel, lysate generated from HEK293 cells was treated with a gradient of GIS-103 and labeled with AX7890 (triangles). Tissue distribution in rats: tissue vs. plasma concentration (T/P) AUC<sub>0-24</sub> ratios after a single oral administration (10 mg/kg) in rats.

## 112

**12-week treatment with glucagon receptor antagonist LY2409021 significantly lowers HbA<sub>1c</sub> and is well tolerated in patients with type 2 diabetes mellitus**

C.M. Kazda<sup>1</sup>, P. Garhyan<sup>2</sup>, R.P. Kelly<sup>3</sup>, C. Shi<sup>4</sup>, C.N. Lim<sup>3</sup>, H. Fu<sup>2</sup>, M. Deeg<sup>2</sup>

<sup>1</sup>Medical department, Endocrinology, Eli Lilly and Company, Suresnes, France, <sup>2</sup>Eli Lilly and Company, Indianapolis, USA, <sup>3</sup>Eli Lilly and Company, Singapore, <sup>4</sup>Pharmanet/i3, Ellicott City, USA.

**Background and aims:** Type 2 diabetes mellitus (T2DM) pathophysiology is characterized by dysregulated glucagon secretion. LY2409021 (LY) is a potent, selective glucagon receptor antagonist that lowers glucose. This double-blind, Phase 2 study examined the margin between LY efficacy and safety by comparing mean changes in HbA<sub>1c</sub> and liver aminotransferases at 3 dose levels; other measures of glycemic control and safety were evaluated.

**Materials and methods:** Patients (pts) aged 18–70 with T2DM (HbA<sub>1c</sub> 6.5%–10%) naïve to antidiabetic medications or taking a stable metformin dose were randomized to LY 10 mg (n=17), 30 mg (n=34), 60 mg (n=26), or placebo (n=10) once a day for 12 weeks.

**Results:** At baseline, mean HbA<sub>1c</sub> for LY 10 mg (8.0%), 30 mg (7.5%), and 60 mg (7.6%) were similar to placebo (7.8%). At 12 weeks, HbA<sub>1c</sub> least-squares mean change from baseline showed all LY dosages improved glycemic control (10 mg: 0.83%, P=0.030; 30 mg: 0.65%, P=0.042; 60 mg: 0.66%, P=0.051) in contrast to placebo (0.11%). Secondary efficacy measures (eg, seven-point self-monitored blood glucose (SMBG) profile) supported superiority of LY over placebo. No significant changes in triglycerides, LDL- or HDL-cholesterol, weight, or blood pressure were observed. Dose-dependent increases in fasting glucagon, alanine aminotransferase (ALT), aspartate aminotrans-

ferase (AST), and total glucagon-like peptide-1 (GLP-1) were observed; these returned to baseline on washout of LY. Pts exposed at endpoint to LY 10 mg showed no significant ALT or AST changes; LY 30 and 60 mg were associated with mean increases ranging from 3.7 to 19.9 U/L. Total, direct, and indirect bilirubin, fasting insulin, and active GLP-1 were unchanged vs. placebo. Eight of 85 pts reported hypoglycemic events, 4 of which were confirmed. Incidence of hypoglycemia was not dose dependent; no severe events were reported. Adverse events frequency was similar with active treatment and placebo.

**Conclusion:** This study demonstrates that glucagon receptor antagonism with LY substantially lowers HbA<sub>1c</sub>. Increases in aminotransferases were evident at higher doses without elevated bilirubin or other signs or symptoms of liver injury. The efficacy, safety, and tolerability profile of LY in pts with T2DM supports further clinical development.

## 113

### Orally active small molecule AdipoRs agonists reduce metabolic stress, leading to anti-aging such as increased mitochondria and amelioration of obesity-related disorders

T. Yamauchi, M. Okada-Iwabu, M. Iwabu, T. Kadowaki;

Department of Metabolic Diseases, University of Tokyo, Japan.

**Background and aims:** Adiponectin secreted from adipocytes has been reported to mimic the effects of exercise via AdipoR1 in muscle. Ca<sup>2+</sup> signaling as well as AMPK and PGC-1 $\alpha$  in muscle are key mediators activated by both exercise and adiponectin. Importantly, in liver, adiponectin activates not only AMPK pathways via AdipoR1 but also PPAR $\alpha$  pathways via AdipoR2, leading to reduced ectopic fat accumulation. Thus, orally active small molecules that could bind to and activate both AdipoR1 and AdipoR2 have been expected to produce a metabolic profile desirable for treating diseases of aging such as type 2 diabetes and atherosclerosis. However, no paper has been published identifying such compounds.

**Materials and methods:** Here we describe the identification of orally active small molecules that could be AdipoR agonists.

**Results:** One of these compounds, AdipoR agonist (ARA)-1, bound to both AdipoR1 and AdipoR2 *in vitro*, and activated AMPK, increased PGC-1 $\alpha$  levels in a Ca<sup>2+</sup> dependent manner and increased the number of mitochondria in myocytes. Orally administered ARA-1 ameliorated insulin resistance and glucose intolerance (insulin resistance index: 100 $\pm$ 9 vs. 57 $\pm$ 4%, vehicle vs. ARA-1,  $P < 0.01$ ) in control, but not in AdipoR1/AdipoR2 double knockout mice fed a high-fat diet. In livers of obese diabetic mice, ARA-1 suppressed molecules involved in gluconeogenesis via AdipoR1, increased PPAR $\alpha$  target genes involved in fatty-acid combustion and reduced oxidative stress via AdipoR2. In muscles, ARA-1 via AdipoR1 increased mitochondrial biogenesis, which was associated with increased exercise endurance, and at the same time increased levels of molecules involved in fatty-acid combustion and in the reduction of oxidative stress. In white adipose tissues (WAT), ARA-1 reduced oxidative stress, the production of pro-inflammatory cytokines, and the accumulation of M1 macrophages. In brown adipose tissues, ARA-1 increased the levels of molecules involved in energy dissipation. Importantly, these effects resulted in reduced tissue triglyceride content and oxidative stress in liver, muscle, and WAT and decreased inflammation in liver and WAT.

**Conclusion:** Thus, small molecule AdipoR agonists are promising novel oral therapies for treating diseases of aging such as type 2 diabetes.

## 114

### Oral salmon calcitonin attenuates hyperglycaemia and preserves pancreatic beta cell mass and function in Zucker diabetic fatty rats

M. Feigh<sup>1</sup>, K. Vietz Andreassen<sup>1</sup>, A.V. Neutzsky-Wulff<sup>1</sup>, C. Hansen<sup>1</sup>, S.T. Petersen<sup>1</sup>, J. Henriksen<sup>2</sup>, H. Beck-Nielsen<sup>2</sup>, C. Christiansen<sup>1</sup>, K. Henriksen<sup>1</sup>, M.A. Karsdal<sup>1</sup>;

<sup>1</sup>Nordic Bioscience, Herlev, <sup>2</sup>Department of Endocrinology M, Odense University Hospital, Odense, Denmark.

**Background and aims:** Oral delivery of the peptide hormone salmon Calcitonin (sCT) possesses glucoregulatory effects in diet-induced obese and insulin resistant rats. In here, we describe a proof of concept study in the Zucker diabetic fatty (ZDF) rat, a model of type 2 diabetes, investigating the effects

of oral sCT on diabetic hyperglycemia and exploring the mode of actions by which it may protect against type 2 diabetes.

**Materials and methods:** Male ZDF rats were treated with oral sCT (0.5, 1.0 or 2 mg/kg) or oral vehicle twice daily from age 8 to 18 weeks. Zucker lean rats served as control group. Fasting and non-fasted blood glucose, HbA<sub>1c</sub> and levels of pancreatic and incretin hormones were determined. OGTT and i.p. glucose tolerance test (IPGTT) were compared and beta-cell mass and function evaluated.

**Results:** Oral sCT treatment dose-dependently attenuated fasting and non-fasted hyperglycaemia during the intervention period. At the end of the study period, oral sCT treatment by dose decreased plasma glucose levels by ~9 mM and reduced HbA<sub>1c</sub> levels by 1.7% compared to vehicle. Furthermore, compared to vehicle, a marked ~60% reduction in glucose excursions was dose-dependently observed for oral sCT treatment during OGTT, although much less pronounced during IPGTT. During the intervention period, in contrast to vehicle, oral sCT treatment sustained hyperinsulinemia, ameliorated hyperglucagonemia and attenuated hypersecretion of the incretin hormone glucagon-like peptide-1. Lastly, oral sCT treatment dose-dependently improved pancreatic beta-cell function and beta-cell area at study end.

**Conclusion:** Oral salmon Calcitonin attenuated diabetic hyperglycemia in ZDF rats by improving postprandial glycemic control, exerting an insulinotropic and glucagonostatic action and by preserving pancreatic beta-cell mass and function.

## OP 20 Insulin: beyond traditional delivery

115

### Buccal spray insulin in subjects with impaired glucose tolerance: improvement in HbA<sub>1c</sub> is lost after 6 months wash out therapy

A. Palermo<sup>1</sup>, N. Napoli<sup>1</sup>, E. Maddaloni<sup>1</sup>, A. Lauria<sup>1</sup>, A. Soare<sup>1</sup>, S. Manfrini<sup>1</sup>, M. Altomare<sup>2</sup>, S. Leotta<sup>2</sup>, P. Pozzilli<sup>1</sup><sup>1</sup>University campus Bio medico, <sup>2</sup>Hospital "S.Pertini", Roma, Italy.

**Background and aims:** subjects who develop type 2 diabetes (TD2) pass through a phase of impaired glucose tolerance (IGT). Defects in the action or secretion of insulin are the two major abnormalities leading to development of glucose intolerance. Resistance to insulin progressively increases when passing from normal glucose tolerance through IGT to diabetes, whereas secretion of insulin gradually decreases. Glucose tolerance is assumed to remain normal as long as the beta cell secretion can compensate for insulin resistance. IGT will develop only when insulin secretion fails to compensate fully for such resistance, resulting in postprandial hyperglycaemia that is linked to an increased risk for cardiovascular disease even though there is no progression to diabetes. Many intervention trials have been conducted in IGT patients but only one aimed to decrease post prandial hyperglycaemia. Our previous proof of concept study in subjects with IGT undergoing a prolonged OGTT demonstrated that treatment with 12 puffs of buccal spray insulin was followed by a significant 29.6% decrease in mean plasma glucose at two-hours and a 26.8% decrease at three-hours. Based on these findings a short trial with buccal spray insulin was planned.

**Materials and methods:** We have designed a randomized controlled trial in patients with IGT comparing a 6 months duration therapy using buccal spray insulin (12 puffs per meal) plus physical exercise and diet (treatment group A, n=16, HbA<sub>1c</sub> at entry 6.2% + 0.4) vs physical exercise and diet only (control group B, n=16, HbA<sub>1c</sub> at entry 6.0% + 0.3). Primary endpoint of this study is the reduction of HbA<sub>1c</sub> of 0.3 % at 6 month treatment between experimental versus control group. Secondary endpoints include the evaluation of antibodies against insulin (IA), changes in body weight, number of hypoglycaemic events during the treatment period and the evaluation of metabolic control at 6 months after the end of the treatment. HbA<sub>1c</sub> levels, metabolic parameters and insulin antibodies were measured at baseline, at 3 months up to 6 months followed by 6 months wash out.

**Results:** Subjects treated with buccal spray insulin achieved a significant reduction of HbA<sub>1c</sub> compared to the control group ( $\Delta$  HbA<sub>1c</sub> 0<sup>-</sup> 6 months -0.3% vs +0.09% p=0.002). At 6 months after the end of treatment, in group A HbA<sub>1c</sub> levels raised from 5.8 % + 0.3 to 6.1 + 0.5 resulting in loss of previous achieved improvement of metabolic control and 19% of the treated patients developed TD2 (vs 6% in the control group). There was no significant difference in body weight and no hypoglycaemic or other adverse events were observed during the study period in both groups. No generation of IA was observed in subjects with IGT treated with buccal spray insulin.

**Conclusion:** These results indicate that buccal spray insulin is an effective treatment compared to diet + physical exercise in patients with IGT in reducing HbA<sub>1c</sub> without adverse effects. However the beneficial effects of buccal spray insulin is lost within few months of suspension of treatment. A larger trial is required to demonstrate the long term effects of this buccal spray insulin in preventing TD2 in subjects with IGT.

### Increase in microcirculatory perfusion after insulin treatment in poorly controlled type 2 diabetic patients: the INSULin regimens and VAScular functions (INSUVASC) study

M. Fysekidis, K. Takbou, Y. Jaber, E. Cosson, P. Valensi;

Diabetes, Endocrinology and Human Nutrition Department, Jean Verdier Hospital, APHP, Bondy, France

**Background and aims:** Insulin induces peripheral vasodilation in healthy subjects. The activity of the autonomic nervous system affects peripheral microcirculation and may be changed by insulin treatment. The long term effect of the improvement of blood glucose control obtained by insulin on microcirculation has not been studied in type 2 diabetic patients. The aim of this study was to examine the changes in cutaneous blood flow (CBF) in poorly

controlled type 2 diabetic patients at fasting and after a standard breakfast, before and after insulin treatment, and the respective role of the improvement of blood glucose control at fasting, post-prandially or both.

**Materials and methods:** The INSUVASC study is a unicenter pilot, randomised, open label study. We included 42 poorly controlled type 2 diabetic patients. CBF was measured during 15 minute periods with a Laser Doppler device (Periflux System 5000\*) at fasting (H0) and one and two hours (H1, H2) after a standardised breakfast that provided 75gr of carbohydrates. Variations in CBF during each period were analysed by spectral analysis for peaks at 0.1 Hz frequency known to represent with sympathetic activity. Measurements were performed before and after a 4-week randomised treatment with three different insulin regimens (Aspart, Detemir or Aspart combined with Detemir).

**Results:** A total of 34 patients completed the study and had good quality Laser Doppler measurements (Aspart, n=8, Detemir, n= 14 or Aspart combined with Detemir, n=12). Age, Body Mass Index, HbA<sub>1c</sub> and fructosamine at baseline did not differ significantly among groups, there were more men in the Detemir group (p= 0.003). CBF changes were expressed as percentages of the first baseline value. CBF increased after breakfast, before (H2: 157±77%, p< 0.001) and after (H2: 185±40%, p=0.005) four weeks of insulin treatment. CBF at fasting increased significantly after insulin treatment (H0: 130 ± 61%, p=0.007), with a similar trend for H1 (p=0.06) but not for H2. Blood flow measured in arbitrary perfusion units after insulin treatment during H0 (p=0,017), H1 (p=0,004) and H2 (p=0,048) correlated with the number of prescribed insulin units / kg of body weight. There were no significant correlations for the same periods before insulin treatment. Spectral analysis showed no significant change for the amplitude of the 0.1 Hz peak. There was no significant difference for the changes in CBF between the three insulin regimens.

**Conclusion:** Cutaneous blood flow increase after meal. The augmentation of CBF at fasting after insulin treatment although may be partly due to the improvement of blood glucose control itself, remains also consistent with the vasodilatory effect of insulin. The absence of changes in sympathetic activity, as shown from the absence of increase of the low frequency peak, suggests that other mechanisms like improved rheological factors, endothelial or myogenic activity may be involved.

### Insulin degludec does not increase antibody formation compared to insulin glargine: an evaluation of phase 3a clinical trials

J. Vora<sup>1</sup>, P. Hollander<sup>2</sup>, S.C. Tamer<sup>3</sup>, T. Johansen<sup>3</sup>, R. Bergenstal<sup>4</sup>;<sup>1</sup>Royal Liverpool University Hospitals, UK, <sup>2</sup>Baylor University Medical Center, Dallas, USA, <sup>3</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>4</sup>International Diabetes Center at Park Nicollet, Minneapolis, USA.

**Background and aims:** Insulin degludec (IDeg) is an ultra-long-acting basal insulin analogue where the threonine in position B30 of human insulin has been omitted and the lysine in position B29 has been coupled to hexadecanedioic acid via a glutamic acid spacer. IDeg forms soluble multi-hexamers upon s.c. injection, resulting in a stable and consistent glucose-lowering effect. All insulin preparations cause some degree of antibody formation in humans, but this has little or no effect on the efficacy or safety of currently marketed products. Here we present antibody data from all phase 3a clinical trials in patients with type 1 or type 2 diabetes where insulin antibody development was analysed for IDeg and compared to insulin glargine (IGlar).

**Materials and methods:** Insulin antibodies were measured in six randomised, controlled, open-label, treat-to-target trials (26 – 52 weeks' duration): two trials in type 1 diabetes (IDeg: n=801; IGlar: n=315) and four trials in type 2 diabetes (IDeg: n=1734; IGlar: n=860). In all trials, IDeg and IGlar were dosed once daily. Insulin aspart was used as bolus insulin in the type 1 diabetes trials. Antibody levels (specific and cross-reacting to human insulin) were measured using specific radioimmunoassays and expressed as percent bound/total radioactivity (% B/T).

**Results:** Across all trials, very few patients developed IDeg- and IGlar -specific antibodies and only at very low levels. Furthermore, mean levels of antibodies cross-reacting to human insulin remained low for both groups throughout the duration of the trials for subjects with type 1 diabetes (10 – 15% B/T) and type 2 diabetes (<6% B/T). For both IDeg and IGlar, Spearman correlation coefficients were calculated on an individual trial basis to investigate the influence of cross-reacting antibodies on HbA<sub>1c</sub>, change from baseline in HbA<sub>1c</sub>, and total daily insulin dose at end-of-trial. All correlation

coefficients were low indicating that there was no clinically relevant influence of insulin antibodies on  $HbA_{1c}$  or dose. Based on scatter plots, there was no difference in  $HbA_{1c}$  or total insulin dose at end-of-trial between patients having cross-reacting antibody levels of >10% B/T and those with levels of <10% B/T. The adverse-event profile in patients with an antibody titre of >10% B/T was generally similar to that of the overall trial population.

**Conclusion:** The immunogenic responses to long-term treatment with IDeg and IGLar are similar and low, with no clinically relevant impact on  $HbA_{1c}$  or total daily insulin dose.

### Reduced postprandial glucose excursion in type 2 diabetic subjects using the InsuPad device

G. Bitton<sup>1</sup>, I. Raz<sup>2</sup>, A. Pfutzner<sup>3</sup>, D. Feldman<sup>1</sup>, T. Alon<sup>1</sup>, L. Liviatan<sup>1</sup>, R. Nagar<sup>1</sup>;

<sup>1</sup>Insuline Medical Ltd., Petach Tikva, Israel, <sup>2</sup>The Diabetes Center, Hadassah Hebrew University School of Medicine, Jerusalem, Israel, <sup>3</sup>IKFE–Institute for Clinical Research and Development, Mainz, Germany.

**Objective:** The pharmacodynamics (PD) and pharmacokinetics (PK) profiles of current insulin analogs are still slow compared to normal physiology. Among other effects this results in large post prandial blood glucose excursions in insulin dependent diabetic subjects (IDDS). InsuLine Medical has developed a technology to accelerate insulin PK profile by applying local controlled heat to the insulin delivery site. This heat increases local blood flow which can induce faster insulin clearance from the injection site which can lead to a better glycemic control. In this study we have tested the effect of the InsuPad device on post prandial glucose during meal tolerance test study.

**Methods:** A meal tolerance test protocol was conducted in type II diabetic subjects using insulin injections with rapid acting insulin analogs. Subjects injected 0.2U/kg before meal and consumed standardized liquid meal (Ensure Plus, Abbott, USA, 474 ml, carbohydrate 100g, protein 26 gm, fat 23 gm). Blood samples for glucose and insulin measurements were taken from a venous line during the whole study. The study was repeated twice with (test) and without (control) the use of the InsuPad device.

**Results:** 10 type II diabetic subjects participated in the study, aged 51 to 68 years [mean - 61.4 years], with  $HbA_{1c}$  of 7% to 9.8% [mean - 8.1%], BMI in the range of 23–35 [mean - 26.5 kg/m<sup>2</sup>] and mean diabetes duration of 24.5 years. The figure below shows the post meal glucose excursion with and without the use of the InsuPad device. Glucose excursion during 250 minutes after meal start ( $G-AUC_{0-250}$ ) was found to decrease when the InsuPad device was used ( $23.9 \pm 43.4$  mg/dL/H with the device vs  $63 \pm 36$  mg/dL/H without the device  $p=0.08$ ), glucose excursion at 120 minutes post meal ( $G_{120}$ ) was found to decrease when the InsuPad device was used ( $28 \pm 65.3$  mg/dl with the device vs  $96.4 \pm 67.5$  mg/dl without the device  $p=0.033$ ) Maximal glucose excursion ( $G_{max}$ ) was also decreased when the InsuPad device was used ( $79.8 \pm 52.2$  mg/dl vs  $136.8 \pm 53.6$  mg/dl  $p=0.053$ )

**Discussion and conclusion:** The above results show a mean reduction of more than 60% in post prandial glucose excursion during 6 hours after meal start. Such a significant decrease if repeated in daily life conditions can significantly improve glycemic control and reduce  $HbA_{1c}$  levels in type II diabetic subjects. Future plans are to increase the number of subjects participating in the study and repeat the study in daily life conditions. Figure 1. Post meal glucose excursion with and without the InsuPad device.

## 119

### Improved pharmacokinetic and pharmacodynamic profile of insulin analogues using InsuPatch, a local heating device

Z. Landau<sup>1</sup>, D. Feldman<sup>1</sup>, A. Shusterman<sup>1</sup>, J. Wainstein<sup>1</sup>, D. Klonoff<sup>2</sup>, I.

Nyberg<sup>2</sup>, D. Lender<sup>3</sup>, O. Mosenzon<sup>3</sup>, I. Raz<sup>3</sup>;

<sup>1</sup>Diabetes Unit, E. Wolfson Medical Center, Holon, Israel, <sup>2</sup>Diabetes Research Institute, Mills-Peninsula Health Services, San Mateo, USA, <sup>3</sup>Diabetes Unit, Hadassah University Hospital, Jerusalem, Israel.

**Background and aims:** The pharmacological profile of rapid acting insulin analogs is still far from mimicking the profile of endogenous insulin release. Studies suggest that heating the insulin injection site may accelerate insulin absorption by increasing local blood flow. InsuPatch is a local heating device intended to accelerate subcutaneous insulin absorption and activity while using an insulin pump, by locally warming the infusion site. The device warms the tissue surrounding the infusion site to 38.5 °C for 30 minutes following the administration of an insulin bolus. The aim of this study was to compare the pharmacodynamic and pharmacokinetic profile of subcutaneous administration of rapid-acting insulin analogs by insulin pump with and without InsuPatch.

**Materials and methods:** Euglycemic glucose clamp tests were performed in 56 subjects with type 1 diabetes, insulin pump users (mean age 33.4±13.5 years, 23 female,  $HbA_{1c}$  7.75±0.85%) after administration of 0.15 units/kg body wt of short-acting insulin analogs, with or without InsuPatch, using a randomized, cross over design. Fifty-five subjects completed the study. Each subject had three clamp procedures: two clamp studies with the InsuPatch device on Day 1 and on Day 3 of a 3-day infusion set cycle and one clamp study without the device on Day 1 of the infusion set cycle (Control). The second clamp study with InsuPatch on Day 3 was undertaken to examine whether there was any effect of increasing duration of infusion site use on the absorption and time action profile of short-acting insulin analogs.

**Results:** The area under the insulin concentration curve during the initial 60 minutes (insulin AUC0-60) was found to increase by 29.7±7% with InsuPatch use compare to control on Day 1 ( $P=0.012$ ). The insulin AUC0-60 was found to increase by 27.9±7% on Day 3 with InsuPatch compare to Day 1 with InsuPatch ( $p<0.05$ ). The table below lists the results for days 1 and 3 under test and control conditions for maximal insulin concentration (C-INSmax), Time to maximum glucose infusion rate (T-GIRmax), and maximal glucose infusion rate (GIRmax). The effect of the device was found to be higher for the subgroup of subjects with  $HbA_{1c}$  above the mean  $HbA_{1c}$  (7.76%,  $n=26$ ); the relative increase in AUC0-60 was 45% ( $p<0.05$ ). The same incidences of local irritations with and without the heating device (on Day 1 and on Day 3) were documented.

**Conclusion:** Administration of short acting insulin analogs to insulin pump treated subjects with type 1 diabetes with InsuPatch, a local heating device, enhances insulin absorption and reduces the duration of glucose-lowering action. This profile may help to achieve better meal insulin coverage and by this mean will permit better control of post-prandial glycemia.

Pharmacological parameters for insulin administration with and without InsuPatch

	InsuPatch Day 1	InsuPatch Day 3	Control Day 1	P; InsuPatch Day 1 vs. Control Day 1	P; InsuPatch Day 1 vs. InsuPatch Day 3
C-INS max [mU/L]	57	69	47	<0.05	<0.05
T-GIR max [min.]	93	78	124	<0.05	0.12
GIR max [mg/kg/min]	5.5	6.5	4.8	0.16	0.08

Clinical Trial Registration Number: NCT01216618

## 120

**In vitro characterisation of novel basal insulin LY2605541: reduced mitogenicity and IGF-IR binding**

R.A. Owens, J.F. Lockwood, J.D. Dunbar, C. Zhang, X. Ruan, S.D. Kahl, H.-R. Qian, J.M. Beals;  
Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, USA.

**Background and aims:** LY2605541 (LY) is insulin lispro with a 20kDa polyethylene glycol (PEG) moiety covalently attached to lysine B28. It is designed to have a large hydrodynamic diameter to reduce subcutaneous absorption and plasma clearance, which should provide a prolonged duration of action that is desired for a basal insulin. Given this design, it is critical to understand the in vitro biological properties of LY in terms of function, selectivity, and mitogenicity.

**Materials and methods:** Zinc-free biosynthetic human insulin, insulin lispro AspB10 insulin, and LY were dissolved in PBS, pH 7.4. Insulin detemir and insulin glargine were purchased, dissolved in diluents, and treated with Chelex 100 resin to remove zinc from the formulations, then dialyzed into PBS or citrate buffer, pH4, respectively. 293HEK cell membranes over-expressing either the human insulin receptor (IR) or the human insulin-like growth factor-1 receptor (IGF-1R) were used in a competitive radioligand scintillation proximity binding assay (SPA) in albumin-free NP-40 binding buffer. A tyrosine phosphorylation ELISA was used to determine the functional activity in IR over-expressing cells. Additional analysis included de novo lipogenesis from [ $^{14}$ C]-Glucose using differentiated 3T3-L1 adipocytes. Since insulin and IGF-1 act through their cognate receptors to increase DNA synthesis and cell proliferation, 2 cell lines—a human osteosarcoma cell line (SAOS2) that expresses more IGF-1R than IR and a rat hepatoma cell line (H4IIE) that expresses only rat IR—provide cellular models for in vitro mitogenicity as determined by methyl- $^3$ H-Thymidine incorporation into the cellular DNA of SAOS-2 cells, and proliferation (Cell Titer, Promega) in the H4IIE cells. Data is analyzed using four-parameter nonlinear regression (Activity Base, IDBS). Results are reported as the dose required to achieve a half-maximal response ( $EC_{50}$ ) compared to the BHI reference standard. The affinity constant ( $K_i$ ) was calculated from the  $IC_{50}$  value using the Cheng-Prusoff equation. All results are the geometric mean  $\pm$  SEM, n.

**Results:** LY shows 17-fold lower binding affinity than insulin lispro at IR ( $7.1 \pm 2.5$  nM; n=3 and  $0.41 \pm 0.02$  nM; n=3, respectively) and >32-fold lower binding affinity than insulin lispro at IGF-1R ( $>1500$  nM; n=3 and  $48 \pm 4$  nM; n=3, respectively). Based on these receptor binding results, LY is more selective than insulin lispro for IR v. IGF-1R ( $>210$ -fold v. 110-fold, respectively). LY is a fully efficacious and potent agonist for IR auto-phosphorylation ( $EC_{50}=20 \pm 2$  nM; n=3) and de novo lipogenesis ( $EC_{50}=16 \pm 4$  nM; n=6). LY shows reduced mitogenic potency compared to insulin lispro in both the IGF-1R-dominant and the IR-dominant cell line (78-fold less and 15-fold less, respectively). In comparison to other insulins, LY shows similar in vitro characteristics for signaling mediated through IR as compared to insulin lispro, insulin detemir, and insulin glargine. LY shows improved selectivity for IGF-1R signaling as compared to insulin lispro and insulin glargine.

**Conclusion:** Even with the reduced binding affinity following PEGylation, LY maintained all of the in vitro characteristics of its parent, insulin lispro, and achieved all of the metabolic and mitogenic characteristics desired in a long-acting insulin.

**Impact of IAPP on the cross-talk between pancreatic endothelial cells and pancreatic islet cells**

M. Visa<sup>1,2</sup>, M. Soty<sup>1,2</sup>, L. Cadavez<sup>1,2</sup>, J.M. Servitja<sup>1,2</sup>, A. Novials<sup>1,2</sup>;  
<sup>1</sup>Diabetes and Obesity Laboratory, IDIBAPS, Hospital Clinic, <sup>2</sup>CIBERDEM, Barcelona, Spain.

**Background and aims:** The close proximity of endothelial cells (EC) and beta-cells suggests that there is a cross-talk between these both cell types. EC produce molecules that could directly influence beta-cell function, such as collagen IV and laminins, which potentiates insulin secretion and proliferation. Nitric oxide (NO) produced by EC also influence beta-cell insulin release. IAPP is a beta-cell secreted peptide which seems to have some effects on endothelial function. Indeed, it has been implicated in vascular tone through a direct interference on NO release by the endothelium. Moreover, preliminary data from our group indicate that treatment of HUVEC cells with IAPP induces expression of VCAM. Taken together, these data suggest that IAPP could play a role on the islet endothelium and therefore affect beta-cell function and proliferation. The main objective of this work is to investigate the effect of IAPP on the cross-talk between pancreatic EC and pancreatic islet cells.

**Materials and methods:** Mouse pancreatic islets were placed on a collagen gel to obtain EC. After one week, EC were recovered and maintained in culture until passage number 8-10. Von Willebrand factor (vWF) and CD31 staining were used to characterize the EC. To analyze the effect of IAPP on EC, we treated EC at several doses of IAPP (10pM-100pM-1000pM) in a time-dependent manner. We measured pAkt/Akt and peNOS/eNOS ratio by western blot, and gene expression of adhesion molecules, ICAM and MCP-1, by real-time PCR. The proliferative capacity was analyzed by PCNA protein expression and BrdU incorporation. To further investigate the effect of IAPP on the cross-talk between pancreatic EC and beta-cells, islets were disaggregated by trypsin treatment to obtain islet cells (DIC). DIC were cultured in the presence or absence of EC treated or untreated with IAPP. The proliferative capacity of islet cells was determined by staining of the Ki67 marker.

**Results:** Western blot analysis showed that IAPP induced phosphorylation of Akt and eNOS in a dose-dependent manner. In addition, IAPP increased PCNA expression and BrdU incorporation. This increase was more important when EC was treated at 100pM IAPP for 48h (PCNA expression: 2.5 fold over untreated cells  $p<0.05$ ; BrdU incorporation: 57.2% compared to untreated cells  $p<0.05$ ). These results show that IAPP stimulates the phosphorylation of Akt and eNOS and that the activation of these signaling molecules mediates the effect of IAPP on EC proliferation capacity. Moreover, EC treated with IAPP showed an increase in the expression of genes related to cell adhesion such as MCP-1 (2.5 fold,  $p<0.05$ ) and ICAM (2.3 fold,  $p<0.05$ ) relative to untreated cells. The co-culture of DIC with an EC basement induced reorganization in cell clusters of DIC, expressing insulin and glucagon. The presence of EC allowed the proliferation of islet cells, which was demonstrated by Ki67 immunolabelling in the nucleus of glucagon and insulin-marked cells. In addition, the co-culture treated with IAPP showed higher proliferative capacity compared to untreated co-culture.

**Conclusion:** We suggest that IAPP induces the proliferative capacity of EC through the activation of the Akt-eNOS pathway and increases the expression of cell adhesion molecules. These effects improve the proliferative capacity of islet cells cultured in the presence of EC.

## 122

**Type 2 diabetes alters the marrow vascular niche and stem cell content through interference with mechanisms controlling cell cycle and survival**

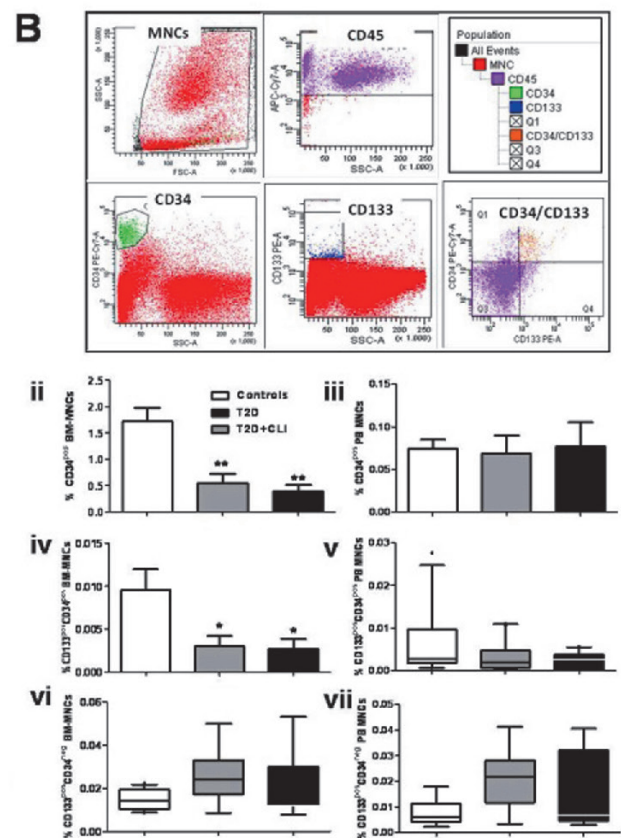

D. Cordella<sup>1</sup>, G. Spinetti<sup>1</sup>, O. Fortunato<sup>1</sup>, E. Sangalli<sup>1</sup>, S. Losa<sup>1</sup>, A. Gotti<sup>1</sup>, F. Carnelli<sup>1</sup>, F. Rosa<sup>1</sup>, A.P. Beltrami<sup>2</sup>, C. Emanueli<sup>3</sup>, P. Madeddu<sup>3</sup>;  
<sup>1</sup>IRCCS MultiMedica, Milan, Italy, <sup>2</sup>University of Udine, Italy, <sup>3</sup>University of Bristol, UK.

**Background and aims:** Circulating progenitor cells (PCs) are reduced in diabetic patients, but underlying mechanisms remain obscure. Here, we propose that diabetes directly affects bone marrow (BM) integrity by impinging upon the miR155/FOXO/p21/p27<sup>kip1</sup> signaling pathway.

**Materials and methods:** BM was obtained from age-matched non-diabetic controls (C) and type 2 diabetic (T2D) patients both undergoing hip replacement, and from T2D patients at occasion of amputation for critical limb ischemia (CLI). BM structure and cellular composition was assessed by histomorphometry, immunostaining, and flow cytometry analyses. Percentage of apoptotic BM-MNCs was measured on paraffin embedded tissue by TUNEL assay. Expression of miR-155 and miR-155 target gene FOXO3A as well as cyclin inhibitors p21 and p27<sup>kip1</sup> was determined in MAC-sorted CD34<sup>pos</sup> PCs. **Results:** Histomorphometry showed that the hematopoietic fraction is reduced in T2D (32%) and T2D+CLI (22%) as compared with C (52%) with fat replacement and bone rarefaction ( $p<0.01$ ). Vascular density was also reduced in both diabetic subgroups ( $p<0.05$ ) with the most prominent defect at capillary level (T2D:  $13\pm4$ , T2D+CLI:  $12\pm2$  and C:  $25\pm2$  cap/mm<sup>2</sup>). Immunofluorescence microscopy and flow cytometry documented the reduction of CD34<sup>pos</sup>CD45<sup>pos</sup> PCs in BM of both diabetic groups, whereas primitive CD133<sup>pos</sup>CD34<sup>neg</sup>CD45<sup>pos</sup> cells did not differ in diabetic and control subjects (Figure 1). Pro-angiogenic PCs, including CD45<sup>dim</sup>CD34<sup>pos</sup>KDR<sup>pos</sup> and CD34<sup>pos</sup>CD14<sup>pos</sup>CD45<sup>dim</sup>KDR<sup>pos</sup>CXCR4<sup>pos</sup> cells, were reduced in BM of T2D ( $0.014\pm0.01\%$ ) T2D+CLI ( $0.023\pm0.008\%$ ) as compared to C ( $0.054\pm0.01\%$ ),  $p<0.05$ , and a similar behavior was observed in peripheral blood (data not shown). Apoptosis is activated in diabetic BM-MNCs especially in patients with CLI (C:  $3.73\pm0.16$ ,  $n=6$ ; T2D:  $5.07\pm0.6$ ,  $n=5$ ; T2D+CLI:  $25.61\pm4.94$ ,  $n=5$ ; % of nuclei positive for DNA fragmentation;  $p<0.05$  vs. C). In line, CD34<sup>pos</sup> PCs sorted from BM of diabetic subjects showed upregulation of the pro-apoptotic factor FOXO3A (T2D: 51-folds and T2D+CLI: 118-folds vs. C,  $n=6$  per group) and downstream cyclin inhibitors, p21 (T2D: 118-folds and T2D+CLI: 79-folds vs. C,  $n=5$ ) and p27<sup>kip1</sup> (T2D: 29-folds and T2D+CLI: 19-folds vs. C,  $n=5$ ;  $p<0.05$  for all comparisons). Moreover, we found that miR-155 is downregulated in CD34<sup>pos</sup> PCs that show FOXO3A levels beyond the 95 percentile of normal distribution. **Conclusion:** Diabetes directly impinges upon BM integrity, causing microvascular rarefaction, shortage of pro-angiogenic cells and activation of pro-apoptotic signalling pathway. These data provide a new key of interpretation for failure of BM to provide an adequate source of regenerative cells in diabetes.

**Figure 1. Reduced abundance of CD34<sup>pos</sup> cells in BM of T2D patients.** A) Representative confocal microscopy photographs showing the presence of CD34<sup>pos</sup> cells among the CD45<sup>pos</sup> (i) and CD45<sup>neg</sup> (ii) cell fractions: CD45<sup>pos</sup> (green arrow), CD45<sup>pos</sup>CD45<sup>pos</sup> (pink arrowhead) and CD34<sup>pos</sup>CD45<sup>neg</sup> cells (red arrow). Nuclei are stained blue with DAPI. ## 123

### microRNA-15a and -16 are increased in circulating pro-angiogenic cells (PACs) of diabetic patients with critical limb ischaemia and impair PAC functions

G. Spinetti<sup>1</sup>, A. Caporali<sup>2</sup>, M. Meloni<sup>2</sup>, O. Fortunato<sup>1</sup>, M. Marchetti<sup>2</sup>, E. Sangalli<sup>1</sup>, E. Faglia<sup>1</sup>, P. Madeddu<sup>2</sup>, C. Emanuelli<sup>2</sup>

<sup>1</sup>IRCCS MultiMedica, Milan, Italy, <sup>2</sup>University of Bristol, UK.

**Background and aims:** Although effective endovascular and surgical therapies have been developed, major amputation is often needed for a large portion of diabetic patients with critical limb ischemia (CLI). Thus, cell therapy to restore blood flow is currently investigated. Relevant to this, number and function of circulating Pro-Angiogenic Cells (PACs) originated from bone marrow is impaired by the disease state with mechanisms that are still poorly understood. Recently, microRNAs (miRs) have been shown to regulate endothelial cell (EC) activities. Here, we aimed to obtain the first characterization human PAC miRs signature associated with CLI and type 2 diabetes (T2D). We further characterized functional impact of miR-15a and -16 on PAC and investigated miR-15a/16 target genes.

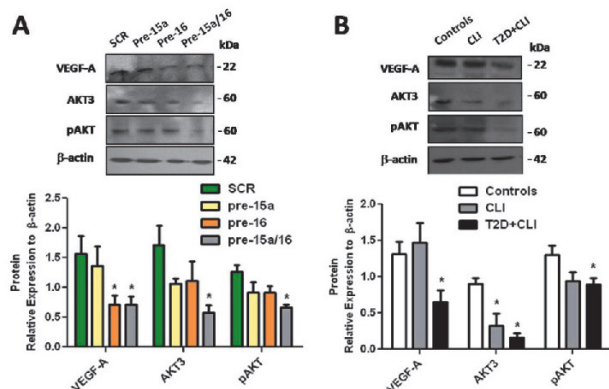

**Materials and methods:** PACs from healthy donors (C) and patients with CLI with/without T2D were enriched by culturing blood mononuclear cells on fibronectin in EC culture medium for 4 days. PACs were screened for 28 miRs expression by TaqMan q-RT-PCR ( $n=7$  samples per group). miR-15a and -16 were further measured in PACs from larger numbers of donors (C:  $n=17$ ; T2D+CLI;  $n=56$ , and non-diabetic CLI:  $n=16$ ). Next, miR-15a and 16 impact on PACs was studied by two complementary approaches: 1) C-PACs were transfected with pre-miR mimics or scramble control and 2) T2D+CLI-PACs with miR inhibitors or scramble. Transwell chambers assay was employed to study PAC migration toward SDF-1 (100 ng/mL), FBS (10%), VEGF-A (100ng/ml), bFGF (100ng/ml) or BSA (control). Bioinformatic analysis using MiRanda, Target Scan, Diana and miRBase softwares was used to predict miR-15a and -16 target genes.

**Results:** PACs from T2D-CLI patients showed de-regulation of several miRs. We focused on miR-15a and miR-16, which were both upregulated in diseased PACs, as also confirmed in the larger number of donors ( $p<0.05$ ). miR-15a and -16 expression in PACs of T2D and non-diabetic CLI ( $n=16$ ) patients were similar ( $p=NS$ ). Overexpression of both miR-15a/16 in healthy-PACs

decreased PACs migration ability toward FBS (57%), SDF-1 (75%), bFGF (59%), or VEGF-A (56%) ( $n=5$ ,  $p<0.05$  for all comparison vs scramble). In line, miR-15a/16 inhibition improved the migratory capacity of T2D+CLI-PACs ( $p<0.05$  vs scramble for all comparisons). VEGF-A and AKT3 were found to be predicted direct target of miR-15a and -16. Moreover, healthy PACs transfected with pre-miR15a/16 as well as patient-derived-PACs showed decreased protein expression of VEGF-A, AKT3, and phospho (p)-AKT (Figure 1).

**Conclusion:** miR-15a and miR-16 are upregulated in PACs of CLI patients (with/out T2D) and impair PAC pro-angiogenic potential, possibly by targeting VEGF-A and AKT-3. Thus miR-15a/-16 may represent new molecular target for *ex-vivo* manipulation of autologous cells used for vascular regeneration.

**Fig. 1. PACs expression of VEGF-A and AKT3, predicted targets of miR-15a and -16.** Western blot analyses of VEGF-A, AKT3 and phospho (p)-AKT in **A**) healthy PACs overexpressing miR-15a and -16 or transfected with SCR control ( $n=9$  subjects,  $*p<0.05$  vs. SCR), and **B**) in PACs from healthy, CLI and CLI+T2D donors ( $n=6$  subjects,  $*p<0.05$  vs. control). **Upper panels:** representative experiments, **lower panels:** bar graphs showing average data  $\pm$  SEM.

### Effects of n-3 polyunsaturated fatty acids on endothelial progenitor cell viability, function and inflammatory molecule expression

V. Spigoni<sup>1</sup>, A. Picconi<sup>2</sup>, M. Cito<sup>2</sup>, V. Ridolfi<sup>2</sup>, C. Casali<sup>2</sup>, E. Usberti<sup>2</sup>, I. Zavaroni<sup>2</sup>, L. Gnudi<sup>3</sup>, M. Metra<sup>1</sup>, A. Dei Cas<sup>2</sup>;

<sup>1</sup>Experimental and Applied Medicine, University of Brescia, Italy,

<sup>2</sup>Department of Internal Medicine and Biomedical Sciences, University of Parma, Italy, <sup>3</sup>Cardiovascular Division, King's College, London, UK.

**Background and aims:** Impairment in the number and function of endothelial progenitor cells (EPCs) has been shown in conditions characterized by an increased cardiovascular (CV) risk such as diabetes. N-3 polyunsaturated fatty acids (PUFA) retain beneficial CV effects due to their antioxidant and anti-inflammatory properties and to their ability to improve endothelial function. No studies are available investigating the effects of these agents on EPC biology. Aim of the study was to evaluate the effects of n-3 PUFA on early and late-outgrowth EPCs cultured *ex vivo*, in terms of viability, function and inflammatory response.

**Materials and methods:** EPCs were obtained from healthy donor buffy coats ( $n=14$ ). Early EPCs were obtained after culturing lymphomonocytes on fibronectin-coated dishes in EGM-2 for 7 days. In the same culture conditions late-outgrowth EPCs were obtained after 3 weeks. EPCs were phenotypically characterized by immunofluorescence and FACS analyses. AcLDL-uptake and lectin-binding capacity were tested. N-3 PUFA (10 $\mu$ M) (DHA:EPA = 1.5:0.9) or vehicle (BSA solution) were added to the culture media to test omega3 effects on EPC viability/proliferation, apoptosis, and function (tube-formation assay by co-plating cells on Matrigel with HUVEC). The effect of n-3 PUFA on pro-inflammatory molecule expression was also tested.

**Results:** The addition of PUFA improved early and late-outgrowth EPC proliferation by 38% ( $p=0.003$ ) and 128% ( $p=0.004$ ) respectively compared to vehicle with negligible effect apoptosis induction. Of note, PUFA prevented H<sub>2</sub>O<sub>2</sub>-induced cell death of late-outgrowth EPCs ( $p=0.004$ ). Furthermore n-3 PUFA enhanced early ( $p=0.015$ ) and late-outgrowth ( $p=0.029$ ) EPC capacity to form tubular-like structures. In the presence of n-3 PUFA, we observed a significantly lower expression of adhesion molecules in early (ICAM-1

$p<0.023$ ) and late-outgrowth (ICAM  $p<0.045$ ; VCAM  $p<0.025$ ) EPCs and of pro-inflammatory cytokines (MCP-1, TNF $\alpha$  and IL8) ( $p<0.05$ ) compared to vehicle.

**Conclusion:** Our data show for the first time a direct beneficial effect of n3-PUFA on EPC biology suggesting a protective role of omega3 on the vascular system possibly mediated by the reduction of inflammation and/or oxidative stress.

## 125

### Exendin-4 inhibits palmitate-induced apoptosis of human cardiac progenitor cells

A. Leonardini, L. Laviola, M.R. Orlando, M. Incalza, A. Pescechiera, A. Natalicchio, S. Perrini, F. Giorgino;  
Endocrinology & Metabolic Diseases, University of Bari, Italy.

**Background and aims:** Multipotent cardiac progenitor cells (CPCs) can be isolated from the adult heart, thus providing a constant tissue renewal. CPC dysfunction and increased apoptosis may contribute to functional abnormalities of the heart observed in metabolic diseases. There is growing evidence suggesting that glucagon-like peptide-1 (GLP-1) and GLP-1-based therapies may promote survival of cardiac cells in environmental stress conditions. The aim of this study was to investigate the protective effects of the GLP-1 receptor agonist exendin-4 on palmitate-induced apoptosis in human CPCs isolated from adult heart biopsies, obtained from the auricle in the course of open heart surgery.

**Materials and methods:** Biopsy-obtained cells showed typical features of mesenchymal multipotent cells, including the differentiation potential toward the adipogenic, osteogenic and chondrogenic lineages, and expression of specific surface markers by flow-cytometry and of lineage-specific intracellular markers GATA-4 and MEF-2C by quantitative real-time PCR. Expression and activation levels of the proteins under investigation were evaluated by immunoblotting techniques. Cell apoptosis was detected by measuring cytosolic oligosomes. Silencing of the GLP-1 receptor was obtained by using specific siRNAs.

**Results:** Acute exposure of CPCs to GLP-1 resulted in a time- and dose-dependent increase in intracellular cAMP levels and CREB phosphorylation, which were abolished in the presence of the GLP-1 receptor antagonist exendin 9-39 or in cells with siRNA-mediated silencing of the GLP-1 receptor. When CPCs were incubated in the presence of 25 mM palmitate for 16 h, a 4-fold increase in cell apoptosis was observed ( $p<0.05$ ). Under the same experimental conditions, incubation with palmitate for shorter times (10-120 min) did not change cell apoptosis. In addition, exposure to 25 mM glucose for up to 16 h had no effect on CPC apoptosis. Preincubation of CPCs with the GLP-1 receptor analogue exendin-4 (20 nM for 16 h) inhibited palmitate-induced apoptosis ( $p<0.05$  vs. palmitate-treated CPCs).

**Conclusion:** Excess palmitate reduces the viability of cardiac precursor cells, whereas high glucose has no effect. Activation of canonical GLP-1 receptors in human cardiac precursors exerts anti-apoptotic actions in the presence of lipotoxicity; this mechanism may contribute to the reported cardioprotective effects of GLP-1 receptor agonists.

### Dipeptidyl peptidase-4 deficiency restores the impaired post-ischaemic mobilisation of haematopoietic and endothelial progenitors in experimental diabetes

M. Albiero<sup>1,2</sup>, L. Menegazzo<sup>1,2</sup>, C. Agostini<sup>1,2</sup>, A. Avogaro<sup>1,2</sup>, G.P. Fadini<sup>1,2</sup>;  
<sup>1</sup>Department of Medicine, University of Padova, <sup>2</sup>Venetian Institute of Molecular Medicine, Padova, Italy.

**Background and aims:** Vascular stem/progenitor cells contribute to cardiovascular homeostasis and are reduced in diabetic patients. Bone marrow mobilization of progenitor cells, which relies on the regulation of SDF-1 $\alpha$ , is impaired in diabetes. SDF-1 $\alpha$  is one substrate of dipeptidyl peptidase (DPP)-4 and diabetic patients have an increased DPP-4 activity. We aimed to determine whether DPP-4 deficiency is able to restore post-ischemic mobilization of progenitor cells in diabetic rats.

**Materials and methods:** We performed quantification of circulating hematopoietic (Sca-1+/c-Kit+) and endothelial (Sca-1+/CD31+) progenitor cells in diabetic and non-diabetic control (wt) and DPP-4 deficient (DPP4null) F344 rats, before and at 3 and 7 days after induction of hind limb ischemia. Dia-

betes was induced by intraperitoneal streptozotocin and experiments were performed 4 weeks after confirmation of hyperglycemia. Muscle capillary density was determined by CD31 immunostaining at day 7 after ischemia.

**Results:** Blood glucose and HbA1c were markedly elevated in diabetic versus non diabetic rats, but there were no differences in DPP4null versus wt animals. DPP-4 activity in DPP4null rats was about 10% of that in wt rats. In wt non diabetic animals, Sca-1+/c-Kit+ and Sca-1+/CD31+ progenitor cells significantly increased 3-fold at day 3 and returned at baseline levels 7 days after ischemia. In wt diabetic rats, progenitor cell mobilization was completely impaired and there were paradoxical reductions in Sca-1+/c-Kit+ and Sca-1+/CD31+ cells at day 3 compared to baseline. In DPP4null diabetic rats, progenitor cell mobilization was restored to levels higher than normal. Recovery of capillary density was impaired in wt diabetic versus non diabetic rats, while it was not significantly reduced in DPP4null diabetic versus non diabetic rats.

**Conclusion:** DPP-4 deficiency restores the impaired post-ischemic mobilization of hematopoietic and endothelial progenitor cells in streptozotocin diabetic rats. This is paralleled by a preserved recovery in the microvascular network of the ischemic tissue.

### Transcriptional regulation of mitochondrial biogenesis in white adipose tissue and control of glucose homeostasis

J.A. Villena<sup>1,2</sup>, N. Enguix<sup>1,2</sup>, R. Pardo<sup>1</sup>, A. González<sup>1</sup>, R. Simó<sup>1,2</sup>, A. Kralli<sup>3</sup>,  
<sup>1</sup>Vall d'Hebron-Research Institute, Barcelona, Spain, <sup>2</sup>CIBERDEM, Barcelona, Spain, <sup>3</sup>The Scripps Research Institute, La Jolla, USA.

**Background and aims:** The endocrine function of adipocytes and their capacity to store triglycerides and prevent ectopic lipid deposition have been shown to be fundamental in the control of glucose homeostasis. In addition, compelling evidence suggests that the mitochondrial oxidative capacity of adipocytes may also exert a great influence on whole body insulin sensitivity. Indeed, mitochondrial dysfunction has been observed in white adipose tissue (WAT) of insulin-resistant individuals, as well as in distinct rodent models of type 2 diabetes. Consistent with an impairment of mitochondrial function, clinical studies have shown that patients with insulin resistance or type 2 diabetes have reduced mitochondrial mass in WAT. Mitochondrial biogenesis is primarily modulated at the transcriptional level by several transcription factors whose activity is coordinated by members of the PGC-1 family of co-activators. The reduced levels of PGC-1α found in WAT of insulin-resistant patients has led to suggest that decreased PGC-1α expression, and the consequent mitochondrial dysfunction, could contribute to the development of type 2 diabetes. However, using an adipose-specific PGC-1α knockout mouse model, we have recently shown that PGC-1α is not required to sustain basal mitochondrial gene expression or function in white adipocytes. We have also shown that PGC-1α is dispensable for rosiglitazone-induced mitochondrial biogenesis in WAT, suggesting that other transcriptional regulators may play a more significant role in the regulation of mitochondrial gene expression in this tissue. Here, we address the function of PGC-1β in WAT and its contribution to the regulation of whole body energy and glucose homeostasis.

**Materials and methods:** To assess *in vivo* the role of PGC-1β in WAT, we have generated a mouse model in which the *ppargc1b* gene has been ablated by homologous recombination specifically in adipocytes (PGC1β-FAT-KO mice). We have also used cultured 3T3-L1 adipocytes in which PGC-1 co-activators have been knockeddown by the use of specific siRNAs to study their contribution to the adipocyte oxidative capacity.

**Results:** Gene expression profiling revealed a significant enrichment in mitochondrial genes among the genes down-regulated in WAT of PGC1β-FAT-KO mice. Interestingly, the PGC-1β target genes identified were mostly restricted to few pathways, such as oxidative phosphorylation and the tricarboxylic acid cycle. Consistent with decreased gene expression, mitochondrial protein content and activity were decreased in WAT of PGC1β-FAT-KO. Moreover, contrary to what we have previously shown for PGC-1α, induction of mitochondrial genes by rosiglitazone was blunted in PGC1β-FAT-KO mice. Similarly, knockdown of PGC-1β in 3T3-L1 adipocytes reduced both, basal and rosiglitazone-induced mitochondrial gene expression and oxygen consumption. However, knockdown of PGC-1α had no effect. Despite the decreased mitochondrial function in WAT, PGC-1β-FAT-KO mice did not exhibit insulin resistance.

**Conclusion:** Our results show that, in WAT, PGC-1β is essential to sustain basal and rosiglitazone-induced expression of mitochondrial genes involved in ATP production. Although lack of PGC-1β impairs adipocyte oxidative capacity, is not sufficient to induce obesity or whole body insulin resistance.

### Effects of the mitochondrial Atp8 mutation on metabolic parameters, life span and expression of respiratory chain complexes after long term high fat diet

H. Weiss, F. Nulle, S. Baltrusch, M. Tiedge;

Institute of Medical Biochemistry, University of Rostock, Germany.

**Background and aims:** The conplastic mouse strain B6-mt<sup>FVB</sup> carries a mitochondrial DNA mutation in the *Atp8* gene coding for the regulatory subunit 8 of ATP-synthase. In comparison to its control strain B6-mt<sup>AKR</sup> the B6-mt<sup>FVB</sup> strain shows impaired glucose tolerance

in response to metabolic stress, induced by high fat diet (HFD). It was the aim of this study to investigate the effects of a long term HFD on glucose/lipid metabolism, expression of respiratory chain complexes in liver and life span. **Materials and methods:** B6-mt<sup>AKR</sup> (AKR) and B6-mt<sup>FVB</sup> (FVB) mice were fed high fat (HFD, 60% fat) or control diet (CD, 10% fat) directly after weaning (week 5). Serum insulin, leptin, triglycerides, cholesterol, i.p. glucose tolerance, i.p. insulin sensitivity, and beta cell mass were investigated at 3, 6, and 12 month of HFD. Respiratory chain complex proteins were quantified by Western blot analyses. Data were analysed by t-test, ANOVA and log rank test.

**Results:** Serum insulin levels were 3-fold elevated in FVB ( $p<0.01$ ) animals already after 3 month of HFD in comparison to CD. Serum insulin levels in AKR mice showed this increase delayed after 6 month of HFD. After 9 and 12 month of HFD serum insulin levels were not different to the CD fed animals in the AKR strain while in FVB mice HFD resulted in a 9-fold increase in serum insulin levels compared to CD ( $p<0.05$ ). The increase of serum insulin levels in HFD fed AKR animals was accompanied by a 3-fold increase of beta cell mass at 6 month of age ( $p<0.001$ ). After 12 month of HFD FVB mice showed a 2-fold increase in serum insulin and 3-fold increase in beta cell mass compared to the situation after 6 month HFD. HFD resulted in significantly elevated serum cholesterol levels after 6 months (FVB:  $p<0.001$ ; AKR:  $p<0.01$ ) and 12 months (FVB/AKR:  $p<0.05$ ) in both strains, while serum triglyceride levels were not affected by HFD at any time point. HFD induced a significant increase of serum leptin levels in FVB mice ( $89 \pm 8$  ng/ml) compared to AKR mice ( $65 \pm 5$  ng/ml;  $p<0.05$ ) animals. After 12 months of HFD serum leptin levels normalized in the AKR strain but remained high in FVB mice. Interestingly, i.p. glucose tolerance and i.p. insulin sensitivity were impaired after 3 months of HFD but normalized gradually until 12 months of HFD in both strains. However, the survival time of HFD fed FVB mice was significantly reduced (68 weeks vs. 80 weeks,  $p<0.03$ ) compared to AKR control mice. Expression levels of respiratory chain complexes in liver showed a significant increase in FVB animals between 3 and 6 months for complex I ( $p<0.01$ ) and complex V ( $p<0.05$ ), but normalized thereafter to the level of AKR controls.

**Conclusion:** The data indicate that the Atp 8 mutation in the ATP-synthase induces a high sensitivity to metabolic stress in early lifetime. In this period compensatory increases of OXPHOS complexes confer adaptation of a pathologic mitochondrial phenotype to metabolic challenges. Interestingly, metabolic parameters normalized despite ongoing HFD. After 12 months of HFD decompensation occurs rapidly with a decreased survival rate of FVB mice. Thus, metabolic challenges at early lifetime could induce changes in mitochondrial dynamics that ultimately will reduce life. Thus, compensated mitochondrial dysfunction in obese adolescents can initiate programs that predispose to mitochondrially-based organ failures at old age.

### Increased lipolysis is associated with enhanced hepatic mitochondrial function and insulin resistance in a mouse model of type 1 diabetes

G.F.B. Séquaris<sup>1</sup>, T. Jelenik<sup>1</sup>, E. Phielix<sup>1</sup>, J. Kotzka<sup>2</sup>, B. Knebel<sup>2</sup>, M. Ouwens<sup>2</sup>, J. Wei<sup>3</sup>, A.L. Reinbeck<sup>1</sup>, P. Nowotny<sup>1</sup>, H.-J. Partke<sup>1</sup>, M. Roden<sup>1,3</sup>, J. Szendroedi<sup>1,3</sup>

<sup>1</sup>Institute for Clinical Diabetology, German Diabetes Center, <sup>2</sup>Institute for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, <sup>3</sup>Department of Metabolic Diseases, University Clinics Düsseldorf, Düsseldorf, Germany.

**Background and aims:** Long-standing type 1 diabetes (T1D) frequently associates with insulin resistance. Although glucose toxicity is held responsible, the mechanism underlying insulin resistance in T1D are not understood. Thus, we aimed to assess the relative roles of glucose and lipid metabolism and mitochondrial function in non-obese diabetic mice (NOD) at three days after the onset of diabetes (short-term diabetic NOD,  $n=20$ ) or in the normoglycaemic state (non-diabetic NOD,  $n=20$ ) and in wild-type C57BL/6 mice (CON,  $n=23$ ) under fasted and postprandial conditions.

**Material and methods:** Muscle and liver insulin sensitivity was measured with hyperinsulinaemic-euglycaemic clamps combined with deuterated glucose. Mitochondrial function was assessed by high-resolution respirometry, mitochondrial biogenesis from peroxisome proliferator-activated receptor gamma coactivator 1- $\alpha$  (PGC-1 $\alpha$ ), transcription factor A, mitochondrial (TFAM) and nuclear respiratory factor 1 (NRF1) by quantitative RT-PCR and mitochondrial content from the ratio of mitochondrial to nuclear DNA using quantitative RT-PCR. Cellular signaling pathways were analysed from phosphorylated c-Jun N-terminal kinase (phospho-JNK), suppressor of cy-

tokine signaling 3 (SOCS3) and insulin receptor substrate-1 (IRS-1) using immunoblotting.

**Results:** Short-term diabetic NOD had lower muscle (-56%,  $p<0.05$  vs. CON and -44%,  $p<0.05$  vs. non-diabetic NOD), but not hepatic insulin sensitivity. They also displayed increased fasting serum triglycerides (+52%,  $p<0.01$  vs. CON and +66%,  $p<0.01$  vs. non-diabetic NOD) and free fatty acids (+57%,  $p<0.01$  vs. CON and +63%,  $p<0.05$  vs. non-diabetic NOD). Furthermore, visceral and subcutaneous fat tissue weights were 63% ( $p<0.01$ ) and 75% ( $p<0.01$ ) lower in diabetic NOD than in CON. Diabetic NOD had 2.4fold and 1.6fold greater hepatic oxidative capacity than in CON ( $p<0.001$ ) and non-diabetic NOD ( $p<0.01$ ) under postprandial conditions. Hepatic mitochondrial biogenesis was also higher (PGC-1 $\alpha$ : 44fold, NRF1: 2.2fold and TFAM: 6.5fold,  $p<0.001$  vs. CON as well as 32fold, 6fold and 4.2fold,  $p<0.001$  vs. non-diabetic NOD). Muscle oxidative capacity was similar in all groups and mitochondrial content was not affected in both tissues. Phospho-JNK was increased by 156% and 72% ( $p<0.05$ ) in muscle and liver of short-term diabetic and non-diabetic NOD compared to CON mice. Likewise, SOCS3 protein levels were increased by 25% ( $p<0.05$  vs. CON) in skeletal muscle and by 20% ( $p<0.05$  vs. CON) in liver of short-term diabetic NOD mice. However, decreased expression of IRS-1 (-47%,  $p<0.01$  vs. CON) was noted only in muscle of diabetic NOD mice.

**Conclusion:** Insulin deficiency at the onset of diabetes causes lipolysis, thereby increasing systemic lipid availability, which stimulates hepatic mitochondrial oxidation. Subsequent activation of inflammatory signaling induces muscle insulin resistance in NOD mice.

## 130

### The “healthy” phenotype of mice with mitochondrial uncoupling in skeletal muscle is linked to increased substrate metabolism and induction of the antioxidant defence system

S. Keipert<sup>1</sup>, A. Chadt<sup>2</sup>, V. Ayala<sup>3</sup>, A. Voigt<sup>1</sup>, M. Ost<sup>1</sup>, M. Portero-Otín<sup>3</sup>, R. Pamplona<sup>3</sup>, H. Al-Hasani<sup>2</sup>, S. Klaus<sup>1</sup>

<sup>1</sup>German Institute of Human Nutrition, Potsdam-Rehbrücke, Germany, <sup>2</sup>German Diabetes-Center, Düsseldorf, Germany, <sup>3</sup>Facultat de Medicina, Lleida, Spain.

**Background and aims:** Transgenic mice with ectopic expression of uncoupling protein 1 (UCP1) in skeletal muscle (SM) mitochondria showed on a high fat diet a delayed development of obesity, improved glucose tolerance and a dramatically 42% increased median lifespan in comparison to their wildtype (WT) littermates. The reason for the increased longevity is not clear so far. It is postulated that mild uncoupling through UCPs affects cellular mitochondrial ROS production and might thus impact aging. We could show a decreased ROS production in isolated mitochondria in UCP1 TG (TG) mice. Another hallmark of TG mice is a body weight independent increased insulin sensitivity. Insulin resistance plays a crucial part in the pathogenesis of the metabolic syndrome and is characterized by a reduced substrate metabolism and impaired defense against stress in skeletal muscle. The aim of this study was to clarify the molecular mechanisms in skeletal muscle which are responsible for the “healthy” phenotype of young UCP1 TG mice.

**Materials and methods:** We investigated body composition and food intake under a low fat (LF) and a high fat (HF) diet. At 20 wks of age (8 wks of dietary intervention) WT and TG mice were killed for SM analysis of substrate metabolism (AMP-activated protein kinase [AMPK], acetyl-CoA carboxylase [ACC], fatty acid translocase CD36, ex-vivo fatty acid oxidation), and oxidative stress parameters including antioxidant defense system (catalase and superoxide dismutase (SOD) activity, heat shock protein (HSP) expression) and oxidative damage markers (glutamic semialdehyde, amino adipic semialdehyde, Nε-[carboxymethyl] lysine, Nε-[carboxyethyl] lysine and Nε-[malondialdehyde] lysine measured by GC/MS).

**Results:** TG mice were resistant against high fat diet induced obesity in younger age. In contrast to WT, TG mice showed no increased body weight or body fat content but increased food intake on a high fat diet in comparison to a low fat diet. In TG animals AMPK activity in SM was significantly increased compared to WT. Furthermore, gene and protein expression analyses of SM pointed to a higher lipid metabolism which was confirmed by an increased ex-vivo fatty acid oxidation in two different muscle types (extensor digitorum longus +85%,  $p=0.004$ ; soleus +54%,  $p=0.038$  in TG mice compared to WT). Interestingly, in contrast to the decreased ROS production in isolated mitochondria, TG mice showed no decreased, but rather a slightly increased ROS damage especially concerning lipid peroxidation products in SM. This was

paralleled by an induction of the endogenous oxidative damage protection system as evident by an increased catalase (LF and HF diet) and SOD (only on HF diet) activity and increased HSP25 protein expression in SM.

**Conclusion:** Our data suggest that SM mitochondrial uncoupling leads to a “healthy” lean phenotype on a high fat diet by preserving insulin sensitivity through increased substrate metabolism and an induction of ROS-signaling pathways. This argues for the mitochondrial hormesis hypothesis suggesting that ROS are essential signaling molecules for health and longevity. In TG mice SM uncoupling seems to act as an exercise mimic leading to an increased energy supply and a mild stress induction which in turn increases the endogenous antioxidant defense system

### Altered electron chain enzyme kinetics between lean, obese and type 2 diabetes mellitus, but no impaired mitochondrial function upon short-term lipid exposure in young humans

E. Phielix<sup>1</sup>, M. Zeppetzauer<sup>1</sup>, G. Sequaris<sup>1</sup>, T. Jelenik<sup>1</sup>, P. Nowotny<sup>1</sup>, J. Szendroedi<sup>1,2</sup>, M. Roden<sup>1,2</sup>

<sup>1</sup>Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf,

<sup>2</sup>Department of Metabolic Diseases, University Clinics Düsseldorf, Germany.

**Background and aims:** Patients with type 2 diabetes (T2D) generally have lower mitochondrial oxidative capacity and plasticity and insulin sensitivity than lean humans (CON). As T2D and lean humans infused with lipids feature increased circulating free fatty acids (FFA) and insulin resistance, lipotoxicity has been suggested to underlie lower mitochondrial function and insulin sensitivity. We examined muscle mitochondrial function in young, glucose tolerant CON, obese humans (OBE) and T2D and in CON upon short-term elevation of circulating FFA.

**Material and methods:** We included 29 CON, 9 OBE and 8 T2D humans (age: 29±2 years, BMI: 23.4±0.6 kg/m<sup>2</sup>, 29.3±2.2 years, 41.4±1.9 kg/m<sup>2</sup>, and 58.5±2.8 years, 35.6±1.2 kg/m<sup>2</sup>,  $p<0.05$  CON vs. OBE and T2D). Participants underwent clamps combined with deuterated glucose. Biopsies were taken from *vastus lateralis* at baseline and in a subgroup of 13 CON- upon 4 hours of Intralipid (20%) before the clamp. Mitochondrial function, including ADP-coupled oxidative capacity on glutamate and succinate (GS3) followed by FCCP-induced uncoupling (state u) as well as enzyme kinetics ( $K_m$ : substrate concentration at which the reaction rate is 50% of maximum speed and  $V_{max}$ : maximal velocity at which the enzyme catalyzes the reaction) of NADH and FADH<sub>2</sub> dehydrogenase, was examined in muscle fibers using high-resolution respirometry.

**Results:** CON were less insulin resistant (IR) than both T2D and OBE (M-value: 9.7±1.0 vs. 2.2±0.8 and 1.6±0.2 mg/kg/min,  $p<0.05$ ). G3 and GS3 were lower in T2D compared to CON (O<sub>2</sub>-flux: 29±4 and 62±8 pmol/mg/s, respectively,  $p<0.05$ ). OBE had a tendency towards lower G3 than CON (40±5 vs. 48±2 pmol/mg/s,  $p=0.06$ ), but no difference in GS3 (69.4±8.3 vs. 79.3±4.3 pmol/mg/s,  $p=ns$ ). State u was lower in T2D and OBE compared to CON (84±8, 97±5 vs. 113±5 pmol/mg/s,  $p<0.05$ ).  $V_{max}$  for NADH dehydrogenase was lower in T2D than in CON and OBE (24.7±9.0 vs. 56±3 and 44±6 pmol/mg/s,  $p<0.05$ ); the  $K_m$  was higher in OBE than in CON and T2D (4.5±0.9 vs. 5.5±0.4 and 2.2±0.5 μmol/l,  $p<0.05$ ). While  $V_{max}$  for FADH<sub>2</sub> dehydrogenase was not different between all groups (66±3, 66±3 and 67±9 pmol/mg/s),  $K_m$  was higher in both OBE and T2D compared to CON (7.6±0.6 and 8.1±2.3 vs. 5.5±0.4 μmol/l,  $p<0.05$ ). Elevation of plasma FFA from 0.48±0.05 to 2.12±0.19 mmol/l ( $p<0.01$ ) resulted in ~60% reduced insulin-stimulated glucose uptake (3.7±0.6 mlkg<sup>-1</sup>min<sup>-1</sup>) but did not affect state 3 and state u respiration (67±4 vs 62±5 pmolmg<sup>-1</sup>s<sup>-1</sup>; state u: 103±7 vs 100±11 pmolmg<sup>-1</sup>s<sup>-1</sup>,  $p=ns$  vs. baseline). Also, enzyme kinetics of NADH and FADH<sub>2</sub> dehydrogenases were not altered.

**Conclusions:** Increased substrate sensitivity of complex (C) 1 and C2 in obese IR but glucose tolerant humans might reflect adaptive upregulation of mitochondrial enzyme activity but reduced maximal capacity as already present in these patients. In patients with overt T2D, substrate sensitivity is increased in C2 but oxidative capacity is impaired in C1, C2 and uncoupled respiration. Although plasma FFA correlate with IR and short-term increase in circulating FFA cause IR, elevation of FFA does not affect mitochondrial function. This supports the contention that muscular IR does not require abnormal mitochondrial function per se.

### Insulin sensitivity does not correlate with mitochondrial function: studies in gastric bypass patients

M.T. Lund<sup>1,2</sup>, M. Hansen<sup>1</sup>, R. Kraunsøe<sup>1</sup>, A. Floyd<sup>2</sup>, K. Bech<sup>2</sup>, F. Dela<sup>1</sup>

<sup>1</sup>Biomedical Sciences, University of Copenhagen, <sup>2</sup>Department of Surgery, Koege Hospital, Denmark.

**Background and aims:** Obesity and type 2 diabetes is accompanied by intramyocellular lipid accumulation. It has been hypothesized that this accumulation leads to mitochondrial dysfunction and insulin resistance. Whether mitochondrial dysfunction is actually present and a cause of insulin resistance is still being debated. Our aim was to compare changes in peripheral insulin sensitivity and mitochondrial respiration after a diet induced weight loss and subsequently by a Roux-En-Y gastric bypass induced weight loss in obese patients with or without type 2 diabetes.

**Materials and methods:** 16 obese patients (4M/12F; 6 with (T2DM) and 10 (OB) without type 2 diabetes) reported thrice to the lab after an overnight fast: Prior to weight loss (A), 2 mo later just prior to operation (B) and 4 mo after operation (C). At each visit three tests were performed: Day 1: Dual Energy X-ray Absorption Scan for body composition and graded bicycle test on a stationary bike for VO<sub>2max</sub>. Day 2: Hyperinsulinaemic euglycemic clamp to measure peripheral insulin sensitivity. Test days were separated by at least 48h. A biopsy were taken from m. vastus lateralis for respirometry prior to the clamp. Muscle fibers were split, permeabilised and rinsed before transferred to the respirometer. Malate (2 mM) and glutamate (10 mM); ADP (5 mM) and magnesium (20 mM); octanoylcarnitine (1.5 mM); and succinate (10 mM) were added consecutively to measure maximally coupled respiration. This was follow by titration of FCCP (steps of 0.25 μM) for maximally uncoupled respiration. Two way ANOVA for repeated measures was used in comparison of the two groups over time.

**Results:** There were no baseline differences in age: 38±10 vs. 40±7 yrs; BMI: 43±1 vs. 41±2 Kg·m<sup>-2</sup>; Fat Free mass (FFM): 60±2 vs. 64±4 kg or VO<sub>2max</sub>: 2.7±0.2 vs. 2.7±0.3 L·min in OB and T2DM, respectively. Weight loss relative to baseline (A) was similar in both groups: 6±1 (1±0.3 kg FFM) vs. 5±1 (1±0.5 kg FFM) kg at exp B and 27±1 (5±0.7 kg FFM) vs. 28±4 (5±2 kg FFM) kg at exp C in OB and T2DM, respectively. VO<sub>2max</sub> did not change significantly during the experiment. Insulin sensitivity measured per fat free mass (GIR<sub>FFM</sub>) and maximally coupled respiration data in the two groups are shown in figure 1. Uncoupled respiration was similar at baseline: 66±3 vs. 67±5 pmol\* mg<sup>-1</sup>s<sup>-1</sup> in OB and T2DM, respectively, and did not change significantly during the experiment.

**Conclusion:** In spite of the marked difference in insulin sensitivity between OB and T2DM, maximally coupled and uncoupled mitochondrial respiration was similar in the two groups. Moreover, with marked improvements in T2DM insulin sensitivity, due to the massive weight loss, mitochondrial respiration remained unchanged. The unchanged VO<sub>2max</sub> indicates that the patients do not take up exercise habits along with their weight loss. In conclusion, our results speak against an association of mitochondrial respiratory capacity and insulin resistance in skeletal muscle in obese and type 2 diabetic patients.

#### Plasma advanced glycation end products are not associated with cardiovascular disease in individuals with or without type 2 diabetes: the Hoorn and CODAM studies

N. Hanssen<sup>1</sup>, L. Engelen<sup>1</sup>, I. Ferreira<sup>1,2</sup>, J. Scheijen<sup>1</sup>, M. Huijberts<sup>1</sup>, M. van Greevenbroek<sup>1</sup>, C. van der Kallen<sup>1</sup>, J. Dekker<sup>3</sup>, G. Nijpels<sup>3</sup>, C. Stehouwer<sup>1</sup>, C. Schalkwijk<sup>1</sup>;

<sup>1</sup>Internal medicine, Maastricht University, <sup>2</sup>Clinical Epidemiology and Medical Technology Assessment, Maastricht University, <sup>3</sup>Epidemiology and Biostatistics, VU University Medical Centre, Amsterdam, Netherlands.

**Background and aims:** Advanced glycation endproducts (AGEs) may contribute to cardiovascular disease (CVD), particularly among individuals with type 2 diabetes (DM2). However, epidemiological evidence supporting an adverse association between increased levels of AGEs and CVD or subclinical markers thereof, in individuals with or without DM2, remains unclear. We therefore investigated, in a large sample of participants with various degrees of glucose metabolism, the associations of plasma concentrations of protein-bound and free forms of AGEs with prevalent CVD and carotid intima-media thickness (IMT) and ankle-brachial index (ABI).

**Materials and methods:** We measured plasma levels of the protein-bound AGEs N<sup>ε</sup>-(carboxymethyl)lysine (CML), N<sup>ε</sup>-(carboxyethyl)lysine (CEL) and free CML, CEL and 5-hydroxy-5-methylimidazole (MG-H1) with ultra-performance liquid chromatography tandem mass spectrometry (UPLC-MS/MS) and protein-bound pentosidine with high-performance liquid chromatography (HPLC), in participants from the Cohort Diabetes and Atherosclerosis Maastricht (CODAM) and the Hoorn Studies. The total combined study sample consisted of 1,291 individuals (mean age 64.5 ± 8.6 years, 45% women) of whom 44% had normal glucose metabolism (NGM), 23% had impaired glucose metabolism (IGM) and 33% had DM2. Data were analysed with multiple linear regression analyses, including adjustments for age, sex, glucose metabolism status and cohort and further for smoking, central obesity, blood pressure, blood lipids, renal function, smoking and use of medication.

**Results:** Protein-bound pentosidine [0.48 (IQR: 0.40–0.59) vs. 0.53 (0.43–0.67) nmol/mmol lysine,  $p=0.013$ ], and free CEL [45 (36–56) vs. 48 (39–62) nmol/l,  $p=0.007$ ] and MG-H1 [116 (84–165) vs. 141 (96–209) nmol/l,  $p<0.001$ ] were significantly increased in individuals with CVD (43% of the study population), but these differences disappeared after adjustment for cohort, age, sex, glucose metabolism status and other traditional cardiovascular risk factors. Plasma protein-bound AGEs (i.e. CML, CEL and pentosidine) and free CEL and MG-H1 were also not independently associated with carotid IMT or ABI, except for a positive association between the free form of plasma CML and ABI [standardized  $\beta=0.106$  (95% CI: 0.064 to 0.148),  $p=0.011$ ]. We did not find any independent associations between the AGEs and study outcomes in analyses stratified according to individuals' glucose metabolism status.

**Conclusion:** Although experimental studies have shown the importance of AGEs in the development of diabetes-related CVD, we found no independent adverse associations of plasma AGEs with CVD, carotid IMT or ABI in two large population-based cohort studies of individuals with NGM, IGM and DM2.

### 134

#### Serum angiogenin which influences vascular repair is related to macrovascular complications of diabetes, but not to diabetes per se

F. Obendorf<sup>1</sup>, M. Ursli<sup>1</sup>, C. Hoebaus<sup>1</sup>, R. Kaltenboeck<sup>1</sup>, G. Pesau<sup>1</sup>, J.-M. Brix<sup>2</sup>, R. Koppensteiner<sup>1</sup>, G. Schernthaner<sup>2</sup>, G.-H. Schernthaner<sup>1</sup>;

<sup>1</sup>Angiology, Medical University of Vienna, <sup>2</sup>Rudolf Foundation Hospital, Vienna, Austria.

**Background and aims:** Patients with diabetes have impaired vascular regenerative function leading to different macrovascular complications like myocardial infarction, stroke or peripheral arterial disease. Angiogenin (ANG), a small polypeptide and potent inducer of vascular growth, is associated with type 2 diabetes and poor glycemic control. Previously, we showed a possible influence of ANG on different microvascular diabetes complications. The aim

of this study was to investigate angiogenin in peripheral arterial disease (PAD). **Materials and methods:** We measured serum levels of ANG in 160 participants, using a commercial available ELISA (R&D systems, Minneapolis, MN): 43 type 2 diabetes without PAD (DM, 44% female, age  $62 \pm 10$  years, HbA1c  $8.3 \pm 1.9$  rel.%, BMI  $30 \pm 5$ ), 35 type 2 diabetes with PAD (DM-PAD, 14% female, age  $69 \pm 8$ , HbA1c  $6.8 \pm 1.1$  rel.%, BMI  $29 \pm 5$ ), 43 PAD patients without DM (PAD, 34% female, age  $68 \pm 11$  years, HbA1c  $5.8 \pm 0.3$  rel.%, BMI  $26 \pm 4$ ) and 38 age-matched healthy controls (CO, 57% female, age  $62 \pm 11$ , HbA1c  $5.8 \pm 0.4$ , BMI  $28 \pm 5$ ). DM-PAD and PAD consisted of patients with Fontaine stage I and II. Data are presented as mean  $\pm$  SD. Statistical analyses included Kolmogorov-Smirnov test, Student's unpaired t-test, ANOVA, univariate correlation analysis, multivariate linear regression modeling and logistic regression modeling, as appropriate.

**Results:** PAD patients with ( $466 \pm 124$  ng/ml) and without DM ( $491 \pm 125$  ng/ml) had significant higher levels of ANG compared to healthy controls ( $367 \pm 144$  ng/ml,  $p < 0.05$ ) and patients suffering from diabetes without PAD ( $368 \pm 145$  ng/ml,  $p < 0.05$ ). ANG levels did not differ between DM and CO ( $p = 0.986$ ), as well as between DM-PAD and PAD ( $p = 0.372$ ). Overall, patients with PAD had significant higher levels of ANG compared to patients and healthy controls without PAD ( $480 \pm 125$  vs.  $369 \pm 143$  ng/ml,  $p < 0.001$ ). Although patients with PAD had significant higher levels of ANG, we failed to show a significant difference between Fontaine stage I and II patients ( $423 \pm 103$  vs.  $491 \pm 131$  ng/ml,  $p = 0.102$ ). Correlation analysis of PAD staging and all available quantitative variables revealed ANG ( $R = 0.392$ ,  $p < 0.001$ ), Age ( $R = 0.291$ ,  $p < 0.001$ ), HbA1c ( $R = -0.419$ ,  $p < 0.001$ ), cholesterol ( $R = -0.194$ ,  $p = 0.020$ ), LDL cholesterol ( $R = -0.200$ ,  $p = 0.016$ ), diastolic blood pressure ( $R = -0.216$ ,  $p = 0.020$ ), as well as mean ankle-brachial index ( $R = -0.540$ ,  $p < 0.001$ ) as significant associates. A logistic regression model for the development of PAD in patients with and without diabetes demonstrated ANG (odds ratio (OR) = 1.007,  $p = 0.001$ ), HbA1c (OR = 0.521,  $p = 0.001$ ) and BMI (OR = 0.861,  $p = 0.012$ ) as significant predictors. To assess and compare the power of prediction of PAD, OR per 1 STD change was calculated. Thus a 1 STD change in ANG, resulted in a 247% increased likelihood of development of PAD. In other words, per 100 ng/ml increase of serum ANG, the risk for PAD increased by 170%.

**Conclusion:** In our study cohort angiogenin was associated with the development and presence of macrovascular disease in patients with and without diabetes. Together with our previous findings, we hypothesize a possible influence of angiogenin on vascular repair function in microvascular and macrovascular diabetes complications.

### Copeptin as biomarker for cardiovascular and all-cause mortality in type 2 diabetes (ZODIAC-31)

I.J. Riphagen<sup>1</sup>, W.E. Boertien<sup>1</sup>, A. Alkhalaf<sup>2</sup>, N. Kleefstra<sup>1,2</sup>, R.T. Gansevoort<sup>1</sup>, K.H. Groenier<sup>2,3</sup>, K.J.J. van Hateren<sup>2</sup>, J. Struck<sup>4</sup>, G. Navis<sup>1</sup>, H.J.G. Bilo<sup>1,2</sup>, S.J.L. Bakker<sup>1</sup>

<sup>1</sup>Internal Medicine, UMCG, Groningen, Netherlands, <sup>2</sup>Diabetes Center, Isala Clinics, Zwolle, Netherlands, <sup>3</sup>General Practice, UMCG, Groningen, Netherlands, <sup>4</sup>BRAHMS GmbH (Thermo Fisher Scientific), Hennigsdorf, Germany.

**Background and aims:** In acute heart failure and myocardial infarction, copeptin, a proximate marker for the antidiuretic stress-hormone vasopressin, has been reported to be of diagnostic and prognostic value. It is not known whether copeptin is also associated with outcome in stable outpatients. This is important, because a positive association would provide rationale for studies on reduction of cardiovascular risk by vasopressin antagonists that recently became available for chronic treatment. Our aim was to prospectively investigate whether copeptin is associated with cardiovascular (CV) and all-cause mortality when assessed from samples obtained during routine check-up of patients with diabetes mellitus type 2 (DM2).

**Materials and methods:** Patients with DM2 participating in the Zwolle Outpatient Project Integrating Available Care (ZODIAC) study were included. Cox regression analyses were used to investigate the association of baseline copeptin levels with cardiovascular and all-cause mortality.

**Results:** We included 1,265 patients (44% male, age  $67 \pm 11.6$  years). Copeptin concentrations were significantly higher in men than in women (median [IQR];  $7.4$  [ $4.4$ – $11.5$ ] versus  $4.1$  [ $2.7$ – $7.3$ ] pmol/L,  $p < 0.001$ ). After median follow-up for  $6.4$  [IQR  $3.2$ – $10.1$ ] years, 365 patients died (29%), with 154 deaths (12%) attributable to CV causes. A Kaplan-Meier analysis for gender-stratified tertiles of copeptin is shown in figure 1. In univariate cox regression analyses, log-transformed copeptin was significantly associated with

CV (Hazard Ratio (HR)(95%CI)=3.03 (1.99–4.62),  $p < 0.001$ ) and all-cause mortality (HR=1.55 (1.41–1.72),  $p < 0.001$ ). These associations remained significant after adjustment for CV risk factors including age, sex, BMI, smoking, systolic blood pressure, total cholesterol-HDL ratio, duration of diabetes, HbA<sub>1c</sub>, use of RAAS-inhibitors, history of CV disease, serum creatinine and urinary albumin-to-creatinine ratio, both for CV (HR=1.18 (1.00–1.39),  $p < 0.05$ ) and all-cause mortality (HR=1.22 (1.10–1.35),  $p < 0.001$ ).

**Conclusion:** We found copeptin to be independently associated with CV and all-cause mortality in patients with type 2 diabetes. Intervention studies should show whether the high CV risk in association with type 2 diabetes can be reduced by chronic treatment with vasopressin antagonists.

### Resistin, major cardiovascular events and all-cause mortality in patients with type 2 diabetes

C. Menzaghi<sup>1</sup>, S. Bacci<sup>2</sup>, L. Salvemini<sup>1</sup>, C. Powers<sup>3</sup>, A. Fontana<sup>4</sup>, S. De Cosmo<sup>2</sup>, F. Pellegrini<sup>4</sup>, A. Doria<sup>3,5</sup>, V. Trischitta<sup>1,6</sup>

<sup>1</sup>Research Unit of Diabetology and Endocrinology, IRCCS, San Giovanni Rotondo, Italy, <sup>2</sup>Unit of Endocrinology, IRCCS, San Giovanni Rotondo, Italy, <sup>3</sup>Joslin Diabetes Center, Boston, USA, <sup>4</sup>Unit of Biostatistics, IRCCS, San Giovanni Rotondo, Italy, <sup>5</sup>Harvard Medical School, Boston, USA, <sup>6</sup>"Sapienza" University, Rome, Italy.

**Background and aims:** We have recently shown that serum resistin is a strong and independent risk factor for incident major cardiovascular events (i.e. cardiovascular death, non fatal myocardial infarction-MI and non fatal stroke) in patients with type 2 diabetes (T2D) comprised in the Gargano Heart Study (GHS). As a first aim, we then decided to investigate whether, in this cohort, resistin improves the ability to predict such incident events as given by traditional clinical variables. In addition, given that cardiovascular disease (CVD) represents the first cause of death in diabetic patients, a second aim was to test the role of serum resistin as a risk factor for all-cause mortality in an independent cohort of patients with T2D (Gargano Mortality Study, GMS).

**Materials and methods:** Serum resistin was associated to incident major cardiovascular events in 350 patients with T2D and coronary artery disease from the GHS. Over a follow-up of 1,108 person-year, 33 cardiovascular deaths, 3 non fatal MIs and 8 non fatal strokes occurred (annual incidence rate=0.04). Predicted risk probabilities were derived from the estimated multivariate Cox regression models considered as established risk models for cardiovascular event in diabetic patients. Survival C statistics, Integrated Discrimination Improvement (IDI) and continuous Net Reclassification Index (cNRI) tests were used to evaluate the incremental prognostic information of serum resistin for major cardiovascular events. The time horizon of risk prediction was set to two years. Serum resistin and all-cause mortality were prospectively evaluated in 783 patients from the Gargano Mortality Study (GMS). Over a follow-up of 5,659 person-year, 150 deaths occurred (annual incidence rate=0.027).

**Results:** Aim 1. As previously described, in multivariable-adjusted analysis, serum resistin was strongly associated with incident major cardiovascular events ( $P = 0.001$ ). At two year follow-up, the addition of serum resistin to the most well established model in T2D including age, sex, smoking habits, HbA<sub>1c</sub> and diabetes duration increased the C-statistic from 0.75 (95% CI: 0.65 to 0.85) to 0.80 (95% CI: 0.73 to 0.87)  $P = 0.037$  and showed an IDI of 2%

( $P=0.05$ ). Finally, the addition of serum resistin allowed to reclassify correctly 139 of the 350 patients ( $P=0.002$ ); 15 (33.1%) and 124 (40.7%) in those with and without incident events, respectively. Aim 2. Serum resistin predicted all-cause mortality with HR per SD increment of 1.14, 95% CI: 1.05–1.22;  $P=0.001$  after adjusting for age, sex, smoking habits, HbA1c and diabetes duration.

**Conclusion:** High serum resistin i) is a strong and independent predictor of incident major cardiovascular events and all-cause mortality in T2D; ii) improves CVD risk stratification based on the most frequently used traditional risk factors. Further studies are needed to confirm the potentially important role of resistin as a novel marker to be implemented in the clinical set for predicting CVD in patients with T2D.

### N-terminal pro-brain natriuretic peptide and cardiovascular mortality in type 2 diabetes: the Casale Monferrato survey

A. Landi<sup>1</sup>, G. Gruden<sup>1</sup>, G. Ghezzo<sup>2</sup>, C. Baldin<sup>2</sup>, C. Amione<sup>1</sup>, A. Schimmenti<sup>1</sup>, L. Spadafora<sup>1</sup>, T. Prinzi<sup>1</sup>, P. Cavallo-Perin<sup>1</sup>, G. Bruno<sup>1</sup>;

<sup>1</sup>Dept. Internal Medicine, Torino, <sup>2</sup>Santo Spirito Hospital, Casale Monferrato, Italy.

**Background and aims:** Circulating levels of N-terminal pro-brain natriuretic peptide (NT-proBNP), a marker of acute heart failure, are associated with increased risk of cardiovascular disease (CVD) in the general population. There is little information on the potential role of NT-proBNP as a biomarker of cardiovascular mortality in diabetic patients and a role of inflammatory markers on this increase has been recently suggested. The aim of this study were to determine: 1) to what extent NT-proBNP values in type 2 diabetic people influences 5-year all causes and cardiovascular mortality, independently on AER and other cardiovascular risk factors; 2) the potential role of CRP on this association.

**Materials and methods:** In the Casale Monferrato Study centralized measurements of NT-proBNP values were available in 1,825 (56.1%) persons out of a population-based cohort of 3,249 persons with diabetes in 2000. They were identified by using independent sources of identification, obtaining an estimated completeness of ascertainment 80%. All measurements were centralized. The independent role of NT-proBNP as predictor of all-cause and cardiovascular mortality in the follow-up period 2000–2006 was assessed with multivariate Cox proportional hazards modeling.

**Results:** Data are based on 390 deaths in 9,101 person-years of observations. A significantly increased mortality risk by quartiles of NT-proBNP was evident ( $p$  for trend  $<0.001$ ), even in people with values in the third quartile. With respect to subjects with NT-proBNP in the lowest quartile ( $<40$  pg/ml), those with values  $>200$  pg/ml had an hazard ratio (HR)=3.05 (95% CI 1.89–4.91) of all-cause mortality and HR=6.99 (95% CI 2.63–18.61) of cardiovascular mortality, after multiple adjustments (Table 1). The inclusion of CRP did not modified results. NT-proBNP has a stronger association with mortality than AER. In people with no CVD at baseline, HR for cardiovascular mortality in the second and in the third quartiles were 3.82 (1.24–13.75) and 3.14 (1.00–9.94).

**Conclusions:** our population-based study indicates that NT-proBNP is a strong independent predictor of short-term mortality risk in type 2 diabetic people, even in those without CVD at baseline. The association between NT-proBNP and mortality is stronger than that provided by AER, is not modified by CRP and is evident even in people with slightly increased values, suggesting its role as an early marker of vascular abnormalities.

### NT-proBNP and long-term all-cause mortality in a cohort of patients with type 1 diabetes

S.S. Diemar<sup>1,2</sup>, A.-S. Sejling<sup>1</sup>, U. Pedersen-Bjergaard<sup>1</sup>, C. Kistorp<sup>3</sup>, J. Faber<sup>3</sup>, B. Thorsteinsson<sup>1,2</sup>;

<sup>1</sup>Department of Cardiology, Nephrology and Endocrinology, Hillerød

Hospital, Hillerød, <sup>2</sup>Faculty of Health Sciences, University of Copenhagen,

<sup>3</sup>Department of Endocrinology, Herlev Hospital, Denmark.

**Background and aims:** Elevated levels of NT-proBNP are associated with increased cardiovascular mortality and excess all-cause mortality in type 1 diabetes with overt nephropathy and in type 2 diabetes independent of urinary albumin excretion. We assessed the relationship between NT-proBNP and all-cause mortality in a cohort of type 1 diabetes with different degrees of albuminuria.

**Materials and methods:** A cohort of 265 patients with type 1 diabetes was followed for 12 years with recording of all-cause mortality. At baseline NT-proBNP was measured and late diabetic complications were recorded. One patient was excluded due to missing NT-proBNP. Of the remaining 264 patients (59% men, age  $45 \pm 13$  years (mean  $\pm$  SD), and duration of diabetes  $21 \pm 12$  years at entry) 25% had renal disease, ranging from microalbuminuria to elevated serum creatinine, and 8% had known macrovascular disease. NT-proBNP levels were categorised in quartiles. Survival data was calculated and Kaplan-Meier survival and Cox regression analyses were performed.

**Results:** The 12-year all-cause mortality was 15% (39 patients). Excess all-cause mortality was associated with the upper NT-proBNP quartile ( $p<0.001$ ) with a relative risk (RR) of 9.1 [95% CI 4.5–18] ( $p=0.003$ ), presence of renal disease ( $p<0.001$ ) and macrovascular complications ( $p<0.001$ ), and male gender ( $p=0.036$ ) but not with smoking ( $p=0.17$ ). When excluding patients with renal disease ( $n=83$ ), mortality in the upper NT-proBNP quartile was increased ( $p<0.001$ ) with no difference between genders ( $p=0.88$ ). When excluding both patients with renal disease and any macrovascular events ( $n=93$ ), belonging to the upper NT-proBNP quartile was still associated with increased all-cause mortality (RR 6.5 [2.1–21] ( $p=0.003$ )), with no difference between genders ( $p=0.34$ ).

**Conclusion:** Elevated levels of NT-proBNP are associated with excess all-cause mortality in type 1 diabetes even when excluding patients with renal and macrovascular disease.

## OP 24 The transcriptome of healthy and stressed beta cells

139

### Quantitative analysis of the human beta cell transcriptome

A.C. Nica, H. Ongen, J.-C. Irminger, S.E. Antonarakis, P.A. Halban, E.T. Dermitzakis;  
Department of Genetic Medicine and Development, University of Geneva, Switzerland.

**Background and aims:** Gene expression shapes phenotypic differences among cell-types, individuals and populations. Transcript abundance provides a direct link between genotype and organismal phenotypes, helping thus to interpret selected disease-predisposing loci. As most phenotypes manifest themselves only in certain tissues, mRNA profiling is most informative in the context of trait-relevant cell-types. Towards this end, we provide here the first detailed description of the human beta cell transcriptome using deep coverage RNA sequencing (RNA-seq) and perform the first comparison of beta cell - islet expression profiles.

**Materials and methods:** Islets were obtained from 11 cadaveric pancreata from individuals without documented diabetes. Islet cells were sorted by FACS to obtain “beta cell” (approx. 90% pure) and also (from 6 preparations) beta-cell depleted “non-beta cell” populations. RNA was extracted and each sample was sequenced in one Illumina HiSeq lane, attaining thus an unprecedented transcriptome resolution (up to 200 million quality filtered reads per sample). Additionally, we sequenced islet DNA from 7 donors at 13 × depth, performed variant calling and detected allele specific effects on expression.

**Results:** As expected, insulin (INS) was by far the most abundantly transcribed gene, followed by INS-IGF2 and IGF2, making up ~ 39%, 9% and 3% of the total nuclear beta cell transcriptome respectively. While the relative percentages are lower, this ranking is maintained in the islet (INS 27%, INS-IGF2 5%, IGF2 1.6%). The ranked correlation between all beta cell and islet-expressed genes is high (Spearman rho = 0.934) and we estimate that 85% of the variance in beta cell gene expression can be explained by using islet expression as proxy. A principal component analysis confirms that beta cell and islet preparations markedly separate from non-beta cells, with insulin, IGF-2, glucagon, transthyretin, pancreatic polypeptide and somatostatin driving most of this separation. We notice a clear clustering of the islet derived RNA-seq data in the context of 20 other tissues, with thyroid, ovary and brain as highest correlating tissue types. Most diabetes susceptibility genes (80% of T1D, 92% of T2D) are expressed in the beta cell, corroborating the cell-type’s essential role in the etiology of the disease. We further characterize the transcriptome by detecting alternative splicing events (defined as changes in frequency of exon pairings) and identifying novel exon junctions. In each sample we observe significant allelic differences in transcript levels at a subset of heterozygous sites, some of which map to diabetes genes or genes for which expression QTLs have been detected in other tissues.

**Conclusion:** In this study we quantify all genes expressed in adult human beta cells, catalogue alternative splicing and allele specific expression events and report the first beta cell - islet expression profile comparison. We thereby provide a valuable resource to the community, aiding our understanding of the genetics of both type 1 and type 2 diabetes.

### Small-Maf factors are involved in the regulation of pancreatic beta cell function in vivo

T. Kondo, H. Nomoto, N. Fujimori, H. Miyoshi, T. Atsumi;  
Medicine II (Immunology and Metabolism), Hokkaido University, Sapporo, Japan.

**Background and aims:** The Maf family, which belongs to leucine zipper transcription factors, consists of two groups, large-Maf and small-Maf factors. MafA, one of the major regulators of insulin gene expression and beta-cell function, is a member of the large-Maf factors and positively regulates insulin gene expression. Our previous study demonstrated small-Maf factors (MafF, MafG and MafK), that lack an N-terminal transactivation domain present in the large-Maf factors, are also expressed in beta cells and thus, can function as a negative regulator. We also showed that both oxidative stress and lipotoxicity reduce insulin gene expression and concomitantly increase both small-

Maf mRNA and protein expressions in a beta-cell line. Here, we evaluated the effect of small-Maf factors on glucose tolerance in vivo.

**Materials and methods:** Three lines of transgenic (Tg) mice with beta-cell specific expression of dominant-negative small-Maf factor (DN-MafK) were established on the C57BL/6J background. All lines of Tg mice showed normal size and growth. Both wild type (Wt) and Tg male mice were fed a regular-chow (R) or high-fat (HF) diet respectively from 6 weeks of age. At 20 weeks, glucose tolerance test was performed and then islets were isolated and analyzed to determine expressions of MafA, small-Mafs and other beta cell-related molecules by real-time RT-PCR and western blot analyses. Pancreatic sections were obtained for immunohistochemistry to evaluate the beta-cell mass and those expressions.

**Results:** There were no significant differences in body weight and food intake between Wt and Tg mice. Feeding HF diet resulted in higher levels of serum insulin and blood glucose, and increased beta-cell mass. Small-Maf and MafA protein expressions were significantly increased. Interestingly, despite similar MafA expression pattern, glucose tolerance in HF diet-fed Tg (HFD-Tg) mice was significantly improved as compared with HF diet-fed Wt (HFD-Wt) mice. HFD-Tg mice showed higher serum insulin level after a glucose load than HFD-Wt mice.

**Conclusion:** Not only MafA but small-Maf factors are important for the regulation of insulin expression in vivo. Inhibition of small-Maf factors in beta cells leads to increment of capability to secrete insulin on demand. Therefore, preventing small-Maf function in beta cells may represent a novel therapeutic target to improve beta-cell function.

### Pancreatic beta cell dedifferentiation into neurogenin3-positive progenitor cells and conversion into non-beta endocrine cells as mechanisms of diabetic beta cell failure

C. Talchai, D. Accili;  
Medicine, Columbia University, New York, USA.

Diabetes is associated with  $\beta$ -cell dysfunction. But it remains unclear whether the latter results from reduced  $\beta$ -cell number or function. We have previously shown that transcription factor FoxO1 integrates  $\beta$ -cell proliferation with adaptive changes during metabolic stress, such as the hyperglycemia of diabetes. Thus, FoxO1 haploinsufficiency is associated with increased  $\beta$ -cell proliferation, while FoxO1 gain-of-function commonly occurs in response to hyperglycemia-dependent oxidative stress, and causes an arrest of  $\beta$ -cell proliferation and a reduced metabolic activity that we have termed “metabolic diapause”. We interrogated the contribution of these two processes (proliferation vs. function) to  $\beta$ -cell dysfunction, using mice lacking FoxO1 in  $\beta$ -cells. FoxO1 ablation caused reduced  $\beta$ -cell mass and hyperglycemia following physiologic (multiparity, aging) and pathophysiologic challenges (chemical  $\beta$ -cell ablation by the toxin streptozotocin, insulin resistance). Surprisingly, lineage-tracing experiments demonstrated that loss of  $\beta$ -cell mass in FoxO1 ablation was due to  $\beta$ -cell dedifferentiation (i.e. loss of  $\beta$ -cell maturation factors such as Pdx1, MafA and Glut2), and not cell death. Dedifferentiated  $\beta$ -cells “regress” to a progenitor-like stage characterized by expression of ChromograninA, and increased levels of Neurogenin3, L-myc, and Hdac1. Moreover, similar lineage-tracing experiments with marker of endocrine non- $\beta$  cells ( $\alpha$ ,  $\delta$ , and Pp cells) indicated that FoxO1-deficient dedifferentiated  $\beta$ -cells partly converted into non- $\beta$  cells, supporting that they retained differentiation potentials, and consequently giving rise to hyperglucagonemia. This is of great interest, in that diabetic patients are characterized by inappropriate hyperglucagonemia that contributes to their disease status. Strikingly, we identify the same sequel of events and dedifferentiation as a common feature of different models of murine diabetes. Our findings indicate that in response to pathophysiological stresses,  $\beta$ -cell differentiation is not terminal but requires FoxO1 to enforce  $\beta$ -cell fate and prevent  $\beta$ -cell conversion. We propose that dedifferentiation trumps endocrine cell death in the natural history of  $\beta$ -cell failure, and suggest that treatment of  $\beta$ -cell dysfunction should aim at restoring  $\beta$ -cell differentiation, rather than increasing  $\beta$ -cell replication.

## 142

**Effects of palmitate treatment on global gene expression in human pancreatic islets**E. Hall<sup>1</sup>, P. Volkov<sup>1</sup>, T. Dayeh<sup>1</sup>, M. Dekker Nitert<sup>2</sup>, C. Ling<sup>1</sup>;<sup>1</sup>Epigenetics & Diabetes, Clinical sciences, Malmö, Sweden, <sup>2</sup>Royal Brisbane Clinical School, Herston, Australia.

**Background and aims:** Chronic exposure to high levels of fatty acids have a negative effect on the beta cell function and hence on insulin secretion. Elevated plasma levels of free fatty acids are often seen in patients with type 2 diabetes and in obese individuals. However, different types of fatty acids can have different effects on pancreatic islets and beta cells. In particular, the long chain saturated fatty acids, such as palmitate and stearate, seem to have a cytotoxic effect. Previous studies in isolated pancreatic islets from rat and mouse have shown that, a long term treatment with palmitate inhibits the glucose stimulated insulin secretion. Additionally, a genome wide expression analysis on MIN6 beta cells revealed differences in the gene expression pattern in cells treated with palmitate compared with control. In this study, we aim to investigate if palmitate treatment for 48 hours affects the genome-wide mRNA expression pattern and glucose-stimulated insulin secretion in human pancreatic islets.

**Materials and methods:** Pancreatic islets from 15 deceased human donors were cultured in control media or palmitate media for 48h. After the 48h incubation, RNA and DNA were extracted. Global gene expression data was obtained using the GeneChip® Human Gene 1.0 ST Array (Affymetrix). The expression data was normalized using the RMA method, and a Wilcoxon signed rank test was performed to detect differences between groups. The results were corrected for multiple testing using FDR analysis and a  $q$  value  $< 0.05$  was considered as significant. Finally, pathway analyses were conducted using the on-line tool Webgestalt. Glucose-stimulated insulin secretion at 16.7 mM glucose was analyzed from 5 replicates of 10 islets per culture condition. **Results:** We identified 1860 genes that were differentially expressed at  $q$  value  $< 0.05$  in human islets exposed to palmitate. Out of these, 1230 genes were down regulated and 630 genes were up regulated due to palmitate treatment. While the down regulated genes included several potassium channels that may affect insulin secretion, several up regulated genes were involved in inflammation. Of the significantly down regulated genes, 1188 had a unique Entrez ID and these were used for pathway analysis. 42 pathways had a  $q < 0.05$  and among the significant pathways we found several pathways involved in metabolism, for example fatty acid metabolism. Out of the significantly up regulated genes, 600 had a unique Entrez ID and these were used for pathway analysis. 6 pathways had a  $q < 0.05$  and among these were for example the PPAR signalling pathway. Finally, glucose-stimulated insulin secretion was impaired in human islets exposed to palmitate compared to control media ( $1.11 \pm 0.07$  vs.  $1.32 \pm 0.08$ ,  $p$ -value 0.046).

**Conclusion:** Our study has identified individual genes and metabolic pathways that are regulated by lipotoxicity in human pancreatic islets. Differential expression of these genes may lead to impaired insulin secretion.

## 143

**Bach1 deficiency protects pancreatic beta cells from oxidative stress injury**K. Kondo<sup>1</sup>, Y. Ishigaki<sup>1</sup>, J. Gao<sup>2</sup>, T. Yamada<sup>2</sup>, J. Imai<sup>1</sup>, S. Sawada<sup>1</sup>, A. Muto<sup>3</sup>, Y. Oka<sup>1</sup>, K. Igarashi<sup>3</sup>, H. Katagiri<sup>2</sup>;<sup>1</sup>Division of molecular metabolism and diabetes, <sup>2</sup>Department of Metabolic Diseases, Center for Metabolic Diseases, <sup>3</sup>Department of Biochemistry, Tohoku University Graduate School of Medicine, Sendai, Japan.

**Background and aims:** BTB and CNC homology 1 (Bach1) is a transcriptional repressor of anti-oxidative enzymes, such as heme oxygenase-1 (HO-1), an inducible enzyme that protects cells in various models of organ injuries. Under oxidative stress, Bach1 loses its DNA-binding activity resulting in activation of transcriptions of oxidative stress-responsive genes. In Bach1-deficient mice, HO-1 is constitutively expressed at higher levels in many tissues, indicating that Bach1 plays a major role in negative regulation of HO-1 expression. A number of previous studies have revealed that a wide range of pathological conditions, including myocardial infarction, atherosclerosis, steatohepatitis, intestine injury, lung injury and neural tissue damage, were prevented in Bach1-deficient mice. Apart from Bach1, induction of HO-1 is known to protect pancreatic  $\beta$ -cells from oxidative injury, and to improve

insulin sensitivity in certain models, such as obese rodents. These findings prompted us to hypothesize that ablation of Bach1 is an encouraging approach to prevent the development of diabetes.

**Materials and methods:** Glucose metabolism in high-fat diet (HFD)-induced insulin resistance and alloxan-induced pancreatic  $\beta$ -cell loss was studied using C57BL/6J wild-type (WT) and homozygous Bach1-deficient C57BL/6J mice. HFD was administered from 6 to 12 weeks of age, and alloxan was injected 50mg/kg to 8 week-old normal chow diet mice. Real-Time PCR and TUNEL staining of the pancreatic islets were performed for further evaluation.

**Results:** The expressions of HO-1 in the liver, white adipose tissue and pancreatic islets were up-regulated 6 to 30 fold in Bach1-deficient mice. In HFD treated mice, no differences were observed in body weight gain, glucose tolerance and in insulin sensitivity between WT and Bach1-deficient mice. In alloxan treated mice, the reduction in pancreatic insulin content was only to 83% in Bach1 deficient mice, while in WT mice, the insulin content was reduced to 46%. In this alloxan model, TUNEL-positive cells in the pancreatic islets of Bach1-deficient mice were markedly decreased, by 60%, compared with those in WT mice.

**Conclusion:** Bach1 has minimal roles in the development of obesity and insulin resistance. Bach1 deficiency-induced HO-1 enhancement has a beneficial impact on oxidative stress-induced  $\beta$ -cell injury.

## 144

**A glucose-regulated cell cycle gene module is selectively lost in pancreatic islets during aging**A. Moreno-Asso<sup>1,2</sup>, A. Grilli<sup>3</sup>, C. Castaño<sup>1,2</sup>, N. Lopez-Bigas<sup>3</sup>, A. Novials<sup>1,2</sup>, J.-M. Servitja<sup>1,2</sup>;<sup>1</sup>Diabetes and Obesity Laboratory, IDIBAPS, <sup>2</sup>CIBERDEM, <sup>3</sup>Biomedical Genomics Group, Universitat Pompeu Fabra, Barcelona Biomedical Research Park (PRBB), Barcelona, Spain.

**Background and aims:**  $\beta$ -cell fate is determined by tightly regulated transcriptional networks that are modulated by extracellular stimuli to allow  $\beta$  cells to adapt to insulin demands. Besides its role as an insulin-secretagogue, glucose is also a potent regulator of gene expression in  $\beta$  cells. Aging is a major risk factor for the development of type 2 diabetes, but the exact contribution of  $\beta$  cells in this process and their capacity to adapt to increased glucose concentrations during aging is still poorly understood. We sought to decipher the glucose-dependent gene modules in mouse pancreatic islets and how this adaptative transcriptional response is altered in aging.

**Materials and methods:** Pancreatic islets from young (6 weeks) and old ( $> 50$  weeks) mice were isolated and cultured at different glucose concentrations. Islet transcriptional profiling was performed by Affymetrix gene expression microarrays and quantitative RT-PCR. Gtools (www.gtools.org) and Gene Set Enrichment Analysis were used to uncover glucose-regulated gene modules.

**Results:** The transcriptional profile of pancreatic islets cultured at 11 mM, the usual in vitro concentration, was the closest to that of fresh islets, indicating that glucose-elicited cues are involved in maintaining the normal  $\beta$ -cell transcriptional program. At severe hypoglycemia (3 mM), the expression of over 15% of islet genes was altered compared to the 11 mM condition. At a basal glucose concentration (5.5 mM), one third of these genes exhibited a similar behavior, but the rest were not affected, indicating that the latter are altered only at severe hypoglycemia. Low glucose levels very rapidly induced the expression of ubiquitous stress genes and nutrient sensors, as well as genes involved in mitochondria biogenesis. The expression of most of these genes rapidly returned to normal levels upon reestablishment of normal glucose levels. By contrast, high glucose concentrations maintained the expression of genes with a more restricted expression pattern such as those involved in  $\beta$ -cell fate acquisition or co-expressed in the nervous system. Of interest, a cell cycle gene module was the most enriched among glucose-induced genes. These genes were already differentially expressed between basal (5 mM) and high (11 mM) glucose levels, suggesting that they may be regulated within the physiological range of glycemia. Unexpectedly, expression profiles of islets from old mice at different glucose concentrations broadly maintained the same profile observed in young islets, except the cell cycle gene module that was selectively lost during aging.

**Conclusion:** Global expression profiling in pancreatic islets has uncovered gene modules regulated by glucose that are likely to be involved in the adaptation of  $\beta$  cells to the nutritional demands of the organism. Although old islets broadly maintained the same transcriptional response to glucose observed in young islets, the regulation of a cell cycle gene module was selectively lost.

This indicates that old  $\beta$  cells maintain most of the glucose-dependent signaling and transcriptional networks except their capacity to proliferate in close correlation to glucose levels.

## OP 25 Intervention studies in type 1 diabetes

### 145

#### Recent data from DIA-AID 1, a global phase III clinical study using DiaPep277 for the treatment of newly diagnosed type 1 diabetes patients

I. Raz<sup>1</sup>, T. Linn<sup>2</sup>, A.-G. Ziegler<sup>3</sup>, G. Scherthanner<sup>4</sup>, F. Bonnici<sup>5</sup>, R. Eren<sup>6</sup>, D. Elias<sup>6</sup>, S. Dagan<sup>6</sup>, P. Pozzilli<sup>7</sup>, On behalf of the DIA-AID 1 Study Group; <sup>1</sup>Diabetes Unit, Department of Medicine, Hadassah University Hospital, Jerusalem, Israel, <sup>2</sup>Universitätsklinikum Giessen, Germany, <sup>3</sup>Institut für Diabetesforschung an der Klinik und Hochschulambulanz für Kinder, München, Germany, <sup>4</sup>Rudolfstiftung Hospital-Vienna, Austria, <sup>5</sup>New Groote Schuur Hospital, Cape Town, South Africa, <sup>6</sup>Andromeda Biotech Ltd., Yavne, Israel, <sup>7</sup>Universita Campus Bio-Medico, Rome, Italy.

**Background and aims:** DiaPep277, a peptide derived from the human heat shock protein 60, immunomodulates the immune system inducing T regulatory cells that prevents destruction and preserves beta-cell function in type 1 diabetes (T1D). DIA-AID 1, a phase III clinical study, was conducted to evaluate the safety and efficacy of DiaPep277 in newly diagnosed T1D patients.

**Materials and methods:** A randomized, double-blinded, placebo-controlled study included patients in the age range of 16–45, not more than 3 months after diagnosis of T1D, a fasting C-peptide > 0.2 nmol/L, and positive islet auto-antibodies. Subjects received 1 mg of DiaPep277 or placebo at 0, 1, 3, 6, 9, 12, 15, 18, 21 months. The efficacy primary endpoint was defined as the change from baseline to end of study in stimulated C-peptide area under curve (AUC) secretion measured by the glucagon stimulated test. Key secondary endpoints included change from baseline to end of study in Mixed-Meal-stimulated C-peptide AUC secretion; proportion of subjects who maintained HbA1c treat-to-target of  $\leq 7\%$  at end of the study, and change from baseline to endpoint in basal fasting C-peptide.

**Results:** 457 patients were randomized. The target population for efficacy included subjects who entered the study according to the major inclusion/exclusion criteria, received at least 1 dose of DiaPep277, and have at least one measurement post baseline (MITT population, n = 422). Significant preservation of C-peptide levels in patients treated with DiaPep277 was demonstrated. The decline in C-peptide AUC from baseline to study end was -3.1 nmol/L in the treated arm compared to -4.1 nmol/L in the placebo, relative treatment effect of 24 %, p=0.037. This preservation was even more significant in patients who completed two years of therapy in full compliance with the study protocol (29% relative change, p=0.011). Furthermore, clinical outcomes support the preservation of beta cells observed by the levels of C-peptide. The percentage of patients who maintained HbA1c levels  $\leq 7\%$  at study end was significantly higher in the DiaPep277 treated group as compared to placebo (56% vs 44%, p= 0.035). Similarly, the proportion of patients who required an insulin dose of less than 0.5 U/K/Day at study end was significantly higher in the treated arm, 59% vs 46%, p=0.0232. Treated patients experienced fewer hypoglycemic events per month, 69 in the treated arm compared to 83 in the placebo. DiaPep277 was well tolerated. No significant differences in drug-related adverse events were reported between the treatment and placebo groups. Additional data are currently being evaluated.

**Conclusion:** DIA-AID 1 met the primary and key secondary endpoints. Patients treated with DiaPep277 preserved their beta-cell function and were better controlled compared to patients on placebo. A second confirmatory phase III clinical study, DIA-AID 2 is currently being conducted worldwide in newly diagnosed adult T1D patients.

Clinical Trial Registration Number: NCT006 15 264

### 146

#### Teplizumab preserves C-peptide in subjects with type 1 diabetes: 2-year results from the Protégé Study

J. Ludvigsson<sup>1</sup>, W. Hagopian<sup>2</sup>, D. Carlin<sup>3</sup>, K.L. King<sup>3</sup>, S. Johnson<sup>3</sup>, E. Bonvini<sup>3</sup>, S. Koenig<sup>3</sup>, A.G. Daifotis<sup>3</sup>;

<sup>1</sup>Div of Pediatrics, Dept of Clin Exp Med, Linköping University, Linköping, Sweden, <sup>2</sup>Pacific Northwest Diabetes Research Institute, Seattle, <sup>3</sup>MacroGenics, Rockville, USA.

**Background and aims:** Teplizumab is an Fc modified, monoclonal antibody that targets the CD3 T-cell receptor (TCR) complex. The Protégé study failed its primary endpoint at 1 year, but showed results in other endpoints, such as

C-peptide, particularly in certain subgroups that suggested a biologic effect. We now report results at 2 years.

**Materials and methods:** In a global, multicenter, double-blind study, 516 subjects with new onset (<12 weeks) T1D were randomized and treated at baseline and 6 months: A. full 14-day regimen; B. 1/3 14-day regimen; C. full 6-day regimen; or D. placebo, and were followed for 24 months. Endpoints included a composite of HbA<sub>1c</sub> <6.5% and insulin <0.5 U/kg/day (primary at 1 year), C-peptide (secondary at 1 and 2 years) by mixed meal tolerance test (MMTT), and adverse events.

**Results:** 513 subjects were dosed: (US 158, India 142, Europe 179, others 34). The full 14-day regimen better preserved C-peptide compared to placebo at 2 years. At study day 140 and months 12, 18 and 24, teplizumab limited the decline in C-peptide in subjects with early T1D. The effect was greatest in subjects <18 years, US subjects, subjects treated ≤6 weeks after diagnosis, and subjects with baseline C-peptide AUC >0.2 nmol/L/min (Table 1). In adults, the rate of C-peptide decline was slower than in younger subjects, and the treated group did not have as great an improvement.

Table 1: Least Square Mean C-peptide Change from Baseline<sup>1</sup> at 2 Years

Group	Full 14-Day Regimen		Placebo		p-value <sup>2</sup>
	N	Mean ± SEM	N	Mean ± SEM	
All Subjects	131	-0.13 ± 0.01	64	-0.19 ± 0.02	0.027
≤6 Weeks	34	-0.07 ± 0.03	14	-0.21 ± 0.04	0.006
USA	30	-0.17 ± 0.03	14	-0.29 ± 0.04	0.010
All with Baseline C-peptide >0.2 nmol/L	112	-0.15 ± 0.02	57	-0.21 ± 0.02	0.036
8–17 years	69	-0.16 ± 0.02	32	-0.23 ± 0.03	0.031
18–35 years	62	-0.11 ± 0.02	32	-0.14 ± 0.03	0.280

<sup>1</sup> Based on least square means obtained from mixed model repeated measures analyses

<sup>2</sup> Unadjusted for multiple comparisons

Subjects who received the full 14-day regimen tended to use less insulin while achieving an HbA<sub>1c</sub> <7% (effect strongest with baseline C-peptide >0.2 nmol/L/min). No differences across groups were observed in the composite endpoint of insulin <0.5 U/kg/day and HbA<sub>1c</sub> <6.5%. Adverse events were more common in teplizumab full 14-day regimen versus placebo, including: mechanism related leukopenia (73% vs 38%) and lymphopenia (86% vs 26%), decreases in neutrophils (47% vs 31%) and eosinophils (6% vs 0%), increased alanine aminotransferase (34% vs 17%) and bilirubin (22% vs 12%). All were transient. Other treatment-related AEs were transient rash (54% vs 20%), pruritus (16% vs 4%), nausea (20% vs 12%), vomiting (15% vs 6%), and chills (10% vs 2%). CRS in ~6% of teplizumab subjects, was managed with antipyretics and antihistamines. No difference was seen in pyrexia, myalgias, arthralgias, overall infections, or SAEs (~12%).

**Conclusion:** The 2-year Protégé results are consistent with those reported at 1 year. Two 14-day courses of teplizumab preserved insulin secretion in early T1D (<12 weeks), especially in subjects with very recent-onset (≤6 weeks) T1D, residual C-peptide (>0.2 nmol/L/min), aged 8–18 years, and in a US population, with an acceptable safety profile.

Clinical Trial Registration Number: NCT00385697

### Alpha-1 antitrypsin therapy in new-onset type 1 diabetes: interim results from Part I of the RETAIN study

M.R. Ehlers<sup>1</sup>, P.A. Gottlieb<sup>2</sup>, K. Herold<sup>3</sup>, M.R. Rigby<sup>4</sup>, S.M. Willi<sup>5</sup>, S. Aggarwal<sup>6</sup>, D. Phippard<sup>6</sup>, D.M. Gelmont<sup>7</sup>, B. Jepsen<sup>8</sup>, J. McNamara<sup>9</sup>, T. Strom<sup>10</sup>, G.C. Weir<sup>11</sup>, RETAIN Study Team;

<sup>1</sup>Clinical Trials Group, Immune Tolerance Network, San Francisco,

<sup>2</sup>Pediatrics, Barbara Davis Center, Aurora, <sup>3</sup>Immunobiology, Yale University, New Haven, <sup>4</sup>Pediatrics, Indiana University, Indianapolis, <sup>5</sup>Pediatrics, Children's Hospital of Philadelphia, Philadelphia, <sup>6</sup>Biomarker & Discovery Research, Immune Tolerance Network, Bethesda, <sup>7</sup>Baxter Healthcare Corporation, Westlake Village, <sup>8</sup>Biostatistics, RhoFed, Inc., Chapel Hill, <sup>9</sup>DAIT, National Institute of Allergy and Infectious Diseases, Bethesda,

<sup>10</sup>Medicine, Beth Israel Deaconess Medical Center, Boston, <sup>11</sup>Joslin Diabetes Center, Boston, USA.

**Background and aims:** Immune modulation in new-onset type 1 diabetes (T1D) has shown some success in clinical trials, but durable disease remis-

sion has not been achieved. Treatment with alpha-1 antitrypsin (AAT) reverses diabetes in the NOD mouse with induction of immune tolerance, and prevents rejection in islet allograft models. In the mouse, AAT appears to be broadly anti-inflammatory and has direct anti-apoptotic effects on beta cells. The RETAIN study is a phase II trial in new-onset T1D patients evaluating the ability of AAT to preserve beta-cell function, and here we report preliminary results from Part I.

**Materials and methods:** Part I of RETAIN is a multicenter, open-label, dose-escalation, safety and pharmacokinetic (PK) study in which autoantibody-positive T1D subjects within 100 days of diagnosis received 6 weekly i.v. infusions of human plasma-derived AAT at 45 mg/kg, followed by a 3-week washout, and then 6 infusions at 90 mg/kg; subjects were divided into an older (16–35 years) and a younger (8–15 years) cohort. Endpoints included safety, PK, and metabolic assessments. Intensive PK sampling was performed during and after infusions 1, 6, 7, and 12. Endogenous insulin secretion was assessed by 2-hour C-peptide AUC in response to a mixed-meal tolerance test at baseline and week 18.

**Results:** 16 subjects were enrolled in the trial and received study drug. All except one completed ≥ 80% of planned AAT infusions; 1 subject discontinued due to a suspected drug rash (grade 2). There were no SAEs and the infusions were generally well tolerated. Mean (± SD) baseline (endogenous) and peak plasma AAT levels after the 6<sup>th</sup> low-dose and high-dose infusions, respectively, were 1.07 ± 0.13, 2.20 ± 0.10, and 3.22 ± 0.33 g/L in the older cohort and 1.20 ± 0.11, 2.11 ± 0.21, and 3.42 ± 0.63 g/L in the younger cohort. Peak AAT levels generally declined by 50% at 48 hours post-infusion, but mean plasma AAT levels remained 50% above endogenous levels 120 hours after the final high-dose infusion. At baseline vs. week 18, mean (± SD) 2-hour C-peptide AUC levels (both cohorts) were 0.714 ± 0.324 and 0.706 ± 0.333 pmol/mL, respectively, while insulin use changed from 0.186 ± 0.161 to 0.176 ± 0.127 U/kg/day in the older cohort and from 0.385 ± 0.308 to 0.294 ± 0.149 U/kg/day in the younger cohort; HbA<sub>1c</sub> (combined) changed from 8.0 ± 1.7% to 6.3 ± 0.9%.

**Conclusion:** AAT infusions are well tolerated in new-onset T1D subjects. Metabolic parameters are stable and C-peptide secretion is preserved at the early time point (18 weeks). Additional follow-up to 2 years is required to assess durability of the effect. Mechanistic studies are underway to determine how AAT functions in vivo and to develop a relevant biomarker of biologic activity, prior to initiating Part II of RETAIN.

### Beta cell function in latent autoimmune diabetes in adults treated with linagliptin versus glimepiride: exploratory results from a 2 year double-blind randomised controlled study

O. Johansen<sup>1</sup>, B. Boehm<sup>2</sup>, V. Grill<sup>3</sup>, P.A. Torjesen<sup>4</sup>, S. Bhattacharya<sup>5</sup>, S. Patel<sup>6</sup>, K. Wetzel<sup>7</sup>, H.-J. Woerle<sup>7</sup>;

<sup>1</sup>Boehringer Ingelheim, Asker, Norway, <sup>2</sup>University of Ulm, Germany,

<sup>3</sup>Norwegian University of Science and Technology, Trondheim, Norway,

<sup>4</sup>Aker University Hospital, Oslo, Norway, <sup>5</sup>Boehringer Ingelheim, Biberach,

Germany, <sup>6</sup>Boehringer Ingelheim, Bracknell, UK, <sup>7</sup>Boehringer Ingelheim,

Ingelheim, Germany.

**Background and aims:** Latent autoimmune diabetes in adults (LADA) is associated with a more rapid decline in β-cell function compared to common type 2 diabetes (T2D). Presently, no treatment modality is drug of choice in LADA. We compared the impact of treatment with the DPP4 inhibitor linagliptin (lina) 5mg/d and the sulphonylurea glimepiride (glim) 1–4mg/d on β-cell function in patients retrospectively identified with LADA who had insufficient glycaemic control despite metformin therapy in a 2 year study.

**Materials and methods:** Patients were classified as LADA if one or more of the autoantibodies assessed (GAD65, ICA, IA-2A, IAA) were present at baseline or any on-treatment visit. GAD was assessed using RIA methodology (cut-off 0.05 [sensitivity 82%/specificity 98.89% in the Diabetes Autoantibody Standardization Program 2010]).

**Results:** The study cohort comprised 1519 patients (16 countries), with assumed common T2D. The prevalence of LADA was 7.8% (n=118). GAD65 was the most prevalent autoantibody (6.5%) whereas ICA (0.3%), IA-2A (1.2%) and IAA (0.2%) were rare. Proportion of patients with ≥2 positive antibodies was 0.4%. Baseline characteristics in GAD65+ LADA patients treated with lina (n=65) or glim (n=53) were fairly well balanced (respective age 59/63 years, BMI 30.3/31.7 kg/m<sup>2</sup> and diabetes duration >5 years 62%/59%). C-peptide was available in a subset and as indicated, GAD65+

patients treated with lina preserved C-peptide significantly better than those treated with glim over a 2 year trajectory (Table). HbA1c reductions were of similar magnitude in the groups.

**Conclusion:** In conclusion, treatment with lina or glim in LADA could have differing impacts on long-term  $\beta$ -cell function. Further research exploring the observed potential modulating impact of lina on LADA is ongoing.

**Table:** Changes in fasting C-peptide over time by treatment and GAD65 autoimmune status

	28 weeks		52 weeks		104 weeks

### Combined pancreas-kidney transplantation in recipients with diabetes end-stage kidney disease improve long-term patient survival

T.G. Jenssen<sup>1,2</sup>, J.-P. Lindahl<sup>1</sup>, T. Leivestad<sup>1</sup>, A. Hartmann<sup>1</sup>

<sup>1</sup>Medicine, Rikshospitalet, Oslo, <sup>2</sup>Department of Clinical Medicine, University of Tromsø, Norway.

**Background and aims:** From 1983 a total of 5885 consecutive patients have received a renal transplant at our national centre. Among these recipients, 629 had end-stage kidney disease due to diabetes mellitus. Traditionally recipients with type 1 diabetes end-stage nephropathy have been offered a simultaneous pancreas and kidney transplantation (SPK) if they were fit, motivated and were below 50–55 years of age. To avoid or reduce time on dialysis recipients with a live kidney donor have generally received a single live donor kidney (LDK) often with the intention of later receiving a pancreas. Due to the increased operative risk of SPK older and co-morbid patients generally have received a single deceased donor kidney (DDK).

**Material and methods:** With this policy the type 1 diabetes patients receiving LDK or SPK are comparable with regard to age and co-morbidity, and differences in outcomes may reflect the metabolic effects of a functioning pancreas transplant. We examined the long-term patient survival of recipients with diabetes end-stage kidney disease grouped by mode of treatment at first transplantation.

**Results:** Patient survival of SPK (n=221), LDK (n=171) and DDK (n=237) is presented in figure 1. Mean follow-up time after transplantation was  $7.1 \pm 5.7$  years. The Kaplan-Meier plots show that survival is superior with combined pancreas-kidney transplantation compared to both LDK and DDK recipients. Actual half-life was 14.1 years for the combination (SPK), 11.5 years for LDK and 6.7 years for DDK recipients. In a Cox regression analysis adjusting for recipient age, we found that receiving a combined graft (SPK) was protective for death compared to both LDK recipients (Hazard Ratio 0.72 (0.54–0.97),  $p=0.029$ ) and DDK recipients (HR 0.50 (0.36–0.68),  $p<0.001$ ). Similarly receiving a single live kidney had a better patient survival compared to receiving a single deceased donor kidney (HR 0.69 (0.52–0.92),  $p=0.013$ ). Ten years cumulative survival proportion was 66.7 % in the SPK population, which we find acceptable in this high risk group.

**Conclusion:** PK recipients have a markedly better long-term survival compared to both DDK and LDK recipients in diabetes end-stage kidney disease. More recipients with type 1 diabetes should be offered a SPK transplantation. Figure 1 Kaplan-Meier plot.

### Cardiac morphology and function in type 1 diabetic patients with successful pancreas transplant alone

M. Occhipinti, L. Rondinini, R. Mariotti, N. Scelza, M. Barsotti, F. Vistoli, G. Amorese, U. Boggi, P. Marchetti;

Dept. Endocrinology and Metabolism, University of Pisa, Italy.

**Background and aims:** Whereas combined pancreas and kidney transplantation is an established procedure for the treatment of T1D patients with end stage renal disease, the role of pancreas transplant alone (PTA) in the therapy of T1D subjects with preserved kidney function is still matter of discussion. Aim of this study was to investigate the effects of PTA on cardiac morphology and function in T1D subjects with more than three years of post transplantation follow-up (FU).

**Materials and methods:** Eighty-eight T1D patients received PTA in our centre, mainly performed by the enteric portal drainage and standard immunosuppression, and with 5 years recipients and graft survival of 98.7% and 76.8%, respectively. A series of 35 consecutive subjects with long-term successful PTA were enrolled. Their main clinical characteristics at transplantation were: age  $38.6 \pm 9.9$  yrs; males/females 13/22; BMI:  $23.6 \pm 2.8$  kg/m<sup>2</sup>; diabetes duration  $26.1 \pm 10.0$  yrs; fasting plasma glucose (FPG)  $256 \pm 99$  mg/dl; HbA1c:  $8.7 \pm 1.8\%$ ; C peptide:  $0.10 \pm 0.13$  ng/ml. Median post-transplant FU was  $5.0 \pm 1.9$  yrs. All patients were examined before and during the FU by the Sonos 5500 echograph, Agilent Technologies, used by a single operator.

**Results:** All patients had maintained PTA function with sustained normoglycemia without exogenous insulin therapy (FPG  $85 \pm 11$  mg/dl, HbA1c  $5.4 \pm 0.4\%$  and C peptide  $2.91 \pm 1.26$  ng/ml, all  $p < 0.001$  compared to pre-PTA values). The following echocardiographic parameters significantly improved ( $p < 0.05$  or less) at the end of the follow up: left ventricular mass index (LVMI) decreased from  $82 \pm 17$  to  $73 \pm 18$  mg/m<sup>2</sup>, posterior wall thickness during diastole (PWTD) decreased from  $8.1 \pm 1.1$  to  $7.0 \pm 1.0$  mm; interventricular septum thickness during diastole (IVSTD) decreased from  $9.3 \pm 1.4$  to  $8.7 \pm 1.3$  mm, left ventricular ejection fraction increased from  $55.3 \pm 4.3$  to  $57.9 \pm 1.7\%$ ,  $p < 0.001$ . No significant change was observed in a group of matched T1D subjects with failed PTA.

**Conclusion:** Successful pancreas transplant alone in T1D patients was associated with improved cardiac morphology and function in our single centre series.

## OP 26 Causes and consequences of diabetic nephropathy

151

### Gender effects on the modulation of RAGE in a model of type 2 diabetic nephropathy

B.E. Harcourt<sup>1</sup>, A. Morley<sup>2</sup>, K.C. Sourris<sup>2</sup>, M.T. Coughlan<sup>2</sup>, F.Y.T. Yap<sup>2</sup>, S.A. Penfold<sup>2</sup>, J.M. Forbes<sup>1</sup><sup>1</sup>Glycation and Diabetes, Mater Medical Research Institute, Brisbane,<sup>2</sup>Glycation and Diabetes Complications, Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

**Background and aims:** Receptor for advanced glycation end products (RAGE) is a known mediator of the vascular complications of type 2 diabetes including nephropathy. Adipose derived estrogens are able to modulate the expression of RAGE via interaction with transcription factors such as SP-1, AP-1 and NF- $\kappa$ B. The aim of this study was therefore to examine if the presence of more pronounced renal disease in males is due to modulation of RAGE by oestrogen in the diabetic kidney.

**Materials and methods:** We utilised male and female diabetic leptin receptor gene deletion mice (db/db, *Lepr*<sup>+/+</sup>C57BL/KsJ, (n=10) and their appropriate non-diabetic littermate controls (db/H *Lepr*<sup>+/+</sup>C57BL/KsJ, n=10). Mice were followed for 18 weeks and became diabetic at 8–10 weeks. Renal dysfunction, glucose homeostasis, hormone profile and biochemical indices were analysed. The renal RAGE profile was analysed via RT-PCR, ELISA and chromatin immunoprecipitation (ChIP).

**Results:** Renal function was impaired in all db/db mice. Urinary albumin excretion rate (AER) and Cystatin C, were increased in db/db vs. db/H mice, and this was more prominent in male vs. female db/db mice ( $p<0.05$ ). Creatinine clearance also declined in male db/db mice. Glycaemic control, was worse in db/db vs. db/H mice ( $p<0.05$ ), but this was not affected by sex. Renal RAGE expression was significantly increased in male db/db vs. db/H ( $p<0.05$ ), which corresponded with disruptions in oestrone:oestradiol ratios. In male db/db mice, transcriptional regulation within the promoter of RAGE occurred via the novel regulation via transcriptional regulator RAGE itself and via ER- $\alpha$  and ER- $\beta$  complexes. In female db/db mice transcriptional regulator RAGE interacted with NF- $\kappa$ B to exacerbate renal dysfunction.

**Conclusion:** This study demonstrated sex specific differences in the regulation of RAGE which specifically occurred via adipose derived estrogen inducible transcription factors, and resulted in significantly worse renal function in male diabetic mice. Adipose derived hormones and their influence on renal RAGE may account for sex differences commonly seen in the development of diabetic renal disease.

152

### Genetic variability in the RAGE gene and sRAGE levels do not predict progression of diabetic nephropathy and diabetes-related morbidity and mortality

K. Kuricová<sup>1</sup>, V. Tanhäuserová<sup>1</sup>, V. Bartáková<sup>1</sup>, L. Pácal<sup>1</sup>, J. Svojanovský<sup>2</sup>, D. Krusová<sup>2</sup>, J. Olšovský<sup>2</sup>, J. Bělobrádková<sup>2</sup>, J. Řehořová<sup>2</sup>, K. Kaňková<sup>1</sup><sup>1</sup>Dept. of Pathophysiology, Faculty of Medicine, Masaryk university,<sup>2</sup>Dept. of Internal Medicine, St. Anne's Faculty Hospital, <sup>3</sup>Dept. of Gastroenterology, Faculty Hospital Brno-Bohunice, Brno, Czech Republic.

**Background and aims:** Activation of the Receptor for Advanced Glycation Endproducts (RAGE) by its ligands triggers intracellular signal cascade leading to proinflammatory shift of cellular phenotype. Sustained RAGE activation as seen in diabetes causes cellular dysfunction participating in the pathogenesis of micro- and macrovascular diabetic complications. Using cross-sectional association study design we have previously identified RAGE “risk” haplotype (for diabetic nephropathy (DN) comprised of minor alleles of htSNPs -429T/C (rs1800625) and 2184A/G (rs3134940). Endothelial cells produce truncated soluble RAGE (sRAGE) that supposedly acts as natural competitive inhibitor of RAGE signalling, however out previous cross-sectional data identified sRAGE levels as a function of GFR rather than compensatory protective mechanism. Using follow-up data from prospective study of diabetic population of South Moravia region of Czech Republic the aim of our study was to analyse genetic data related to the RAGE gene and sRAGE levels as potential biomarkers of adverse outcomes of diabetes.

**Materials and methods:** Study comprised a total of 412 diabetic subject with variable stage of DN (i.e. normoalbuminuria (n=75), persist. microalbuminuria (n=96), proteinuria (n=147) and ESRD (n=94)) prospectively followed for a median of 39 [IQR 21 - 59] months. Following end-points were considered: [1] progression of DN by stage, [2] major cardiovascular event (MCVE, non-fatal myocardial infarction or stroke, limb amputation) and [3] all-cause mortality (ACM). Genotyping of RAGE variants (-429T/C, -374T/A, G82S, 1704G/T, 2184A/G, 2245G/A) was performed by methods based on PCR. Baseline serum concentration of sRAGE were measured using ELISA (plasma samples were available in 214 subjects). Software PHASE was used to estimate population haplotype frequencies. Kaplan Meier time-to-event analysis was carried out to ascertain contribution of studied parameters to the three endpoints.

**Results:** Comparison of allele and genotype frequencies of RAGE variants between subjects with and without DN revealed differences only in allele and genotype frequencies of 2245G/A polymorphism (chi-square test,  $P=0.0047$  and 0.0148, respectively). Frequencies of the RAGE risk haplotype did not differ significantly ( $P>0.05$ ). Cumulative incidence of progression of DN was 22.9 %, MCVE 8.2 %, and ACM 19.8 %. No significant effects were ascertained for the carrier state of RAGE genotypes/haplotypes and progression of DN, MCVE and ACM (all  $P>0.05$ , log-rank test). For analogous analysis with sRAGE level, subjects were divided into two groups according to the median of sRAGE. We did not identify any significant difference in studied end-points between the groups (all  $P>0.05$ , log-rank test).

**Conclusion:** Our results indicate that neither genetic variation in RAGE gene nor sRAGE level could be used as a robust predictor of diabetes-associated morbidity or mortality.

### Allelic variations in the superoxide dismutase 2 (SOD2) gene and diabetic nephropathy in subjects with type 1 diabetes

K. Mohammedi<sup>1,2</sup>, S. Maimaitiming<sup>1</sup>, N. Emery<sup>1,3</sup>, N. Bellili-Muñoz<sup>1</sup>, R. Roussel<sup>1,3</sup>, F. Fumeron<sup>1,3</sup>, S. Hadjadj<sup>4,5</sup>, M. Marre<sup>1,3</sup>, G. Velho<sup>1</sup><sup>1</sup>Research Unit 695, INSERM, Paris, <sup>2</sup>Department of Diabetology,Endocrinology and Nutrition, Bichat Hospital, Paris, <sup>3</sup>UFR de Médecine, Univ Paris Diderot, Sorbonne Paris Cité, Paris, <sup>4</sup>Research Unit 927, INSERM, Potiers, <sup>5</sup>UFR de Médecine et Pharmacie, Université de Poitiers, France.

**Background and aims:** Oxidative stress is involved in the pathophysiology of diabetic nephropathy. Manganese superoxide dismutase (Mn-SOD or SOD2) catalyses the dismutation of superoxide, regulates the metabolism of reactive oxygen species in the mitochondria and is highly expressed in the kidney. We investigated associations of SOD2 allelic variations with diabetic nephropathy in type 1 diabetic subjects.

**Materials and methods:** Eight SNPs in the SOD2 region were analysed in 1285 Caucasian type 1 diabetic patients from the SURGENE prospective study (n=340; 10-year follow-up), Genesis France-Belgium (n=501) and GENEDIAB (n=444) cross-sectional studies. The variants give information on ~90% of the allelic variation of SNPs with minor allele frequency  $\geq 5\%$  in haplotype blocks containing SOD2. Incipient nephropathy was defined as persistent microalbuminuria (UAE = 30–300 mg/24 h); established nephropathy as macroalbuminuria (UAE >300 mg/24 h) and plasma creatinine <150  $\mu$ mol/l; and advanced nephropathy as macroalbuminuria and plasma creatinine >150  $\mu$ mol/l or renal replacement therapy. Cox proportional hazards and logistic regression analyses were used to estimate hazard ratios (HR) or odds ratios (OR) for incidence and prevalence of nephropathy. The prevalence of proliferative retinopathy was different in the 3 cohorts (10%, 44% and 82%, respectively) and thus, all analyses were adjusted or stratified by retinopathy stages.  $p\leq 0.01$  was significant.

**Results:** In the SURGENE study, the major T-allele of a functional variant (rs4880, c.T47C, p.V16A) was associated with the prevalence of established/advanced nephropathy at baseline (OR 3.13, 95% CI 1.23 - 8.73,  $p=0.01$ ), with the incidence of microalbuminuria (HR 1.54, 95% CI 1.11 - 2.11,  $p=0.01$ ), with the incidence of renal events (defined as progression to a more severe stage of nephropathy; HR 1.42, 95% CI 1.12 - 1.77,  $p=0.004$ ) and with glomerular filtration rate decline during follow-up (TT:  $-3.96 \pm 0.89$ , CT:  $-1.57 \pm 1.05$ , CC:  $-0.64 \pm 1.12$  ml/min/year,  $p=0.003$ ). Similar results were observed for rs2758329 and rs8031. Pooled cross-sectional analyses were performed in Genesis and GENEDIAB cohorts with stratification by retinopathy stage (non-proliferative/pre-proliferative vs proliferative) and appropriate covariable adjustments to take into account cohort differences. Associations with established/advanced nephropathy were replicated in the subset of subjects

without proliferative retinopathy: OR 4.65, 95% CI 1.64 - 13.82,  $p=0.005$  for rs4880; OR 4.34, 95% CI 1.58 - 12.48,  $p=0.005$  for rs2758329; OR 3.94, 95% CI 1.43 - 11.32,  $p=0.009$  for rs8031. No associations were observed in the subset of subjects with proliferative retinopathy. Results were confirmed in haplotype analyses in all cohorts.

**Conclusion:** SOD2 allelic variations were associated with the prevalence and incidence of diabetic nephropathy and with a faster decline in GFR in type 1 diabetic subjects. These results are consistent with a major role for SOD2 in the protection against oxidative stress and kidney disease in type 1 diabetic patients.

### Assessment of urinary adiponectin as a predictor of progression for diabetic nephropathy in type 1 diabetes

M. Saraheimo<sup>1,2</sup>, N.M. Panduru<sup>3,4</sup>, C. Forsblom<sup>1,2</sup>, L.M. Thorn<sup>1,2</sup>, J. Wadén<sup>1,2</sup>, A. Bierhaus<sup>5</sup>, P. Humpert<sup>6</sup>, P.-H. Groop<sup>1,2</sup>;

<sup>1</sup>Department of Medicine, Helsinki University Central Hospital, Finland,

<sup>2</sup>Folkhälsan Research Center, Helsinki, Finland, <sup>3</sup>"Carol Davila" University

of Medicine and Pharmacy, Bucharest, Romania, <sup>4</sup>Life Memorial Hospital,

Bucharest, Romania, <sup>5</sup>Department of Medicine I and Clinical Chemistry,

University of Heidelberg, Germany, <sup>6</sup>Stoffwechselzentrum Rhein Pfalz,

Mannheim, Germany.

**Background and aims:** Serum adiponectin has been shown to predict progression of diabetic nephropathy (DN) in type 1 diabetes. Urinary adiponectin was also associated with overt nephropathy in cross-sectional studies in type 2 diabetes, but there are no data regarding the role of urinary adiponectin in the progression of DN in patients with type 1 diabetes. The aim of this study was to assess the predictive value of urinary adiponectin, for the progression at any stage of DN.

**Materials and methods:** This survey is part of the Finnish Diabetic Nephropathy Study. At baseline, out of 2201 patients with type 1 diabetes 1451 had normal AER, 319 microalbuminuria and 320 macroalbuminuria. In addition, 111 non-diabetic subjects were studied. Patients were followed for a median of 5.8 years (95% CI 5.7 - 5.9) during which 101 patients progressed from normo- to microalbuminuria, 42 from micro to macroalbuminuria and 71 from macroalbuminuria to ESRD. Urinary adiponectin levels were measured by ELISA and adjusted with u-creatinine. Different Cox proportional hazard models for the progression at every stage of DN were constructed and used to evaluate the predictive value of urinary adiponectin at any stage of DN.

**Results:** In a cross-sectional analysis, urinary adiponectin significantly increased with worsening nephropathy stage (normo 0.0628 vs micro 0.110 vs macro 0.623  $\mu\text{g}/\mu\text{mol}$ ,  $p<0.0001$ ) and was higher in patients with normal AER than in non-diabetic subjects. In Cox regression analyses, when adjusted for sex and the stage specific progression models, urinary adiponectin predicted progression to a higher stage in the microalbuminuria group (OR=1.37, [95%CI 1.04 - 1.80],  $p=0.025$ ) and also progression to ESRD in the macroalbuminuria group (OR=1.03, [95%CI 1.01 - 1.05],  $p<0.0001$ ). When we compared AER (current gold standard) and urinary adiponectin ROC curves for the prediction of progression to ESRD in the macroalbuminuria group there was no significant difference between the areas under curve ( $\Delta_{\text{AUCs}}=0.00867$ ,  $p=0.17$ ).

**Conclusion:** Urinary adiponectin may serve as a novel biomarker for DN and is as accurate as AER for the prediction of progression to ESRD in patients with macroalbuminuria.

## 155

### Copeptin, a surrogate marker for vasopressin, is associated with chronic kidney disease progression in patients with diabetes mellitus (ZODIAC-33)

W.E. Boertien<sup>1</sup>, I.J. Riphagen<sup>1</sup>, I. Drion<sup>2</sup>, A. Alkhalaf<sup>2</sup>, S.J.L. Bakker<sup>1</sup>, K.H. Groenier<sup>3</sup>, J. Struck<sup>4</sup>, H.J.G. Bilo<sup>2,5</sup>, N. Kleefstra<sup>2,5</sup>, R.T. Gansevoort<sup>1</sup>;

<sup>1</sup>Nephrology, UMCG, Groningen, Netherlands, <sup>2</sup>Diabetes Centre, Isala

Clinics, Zwolle, Netherlands, <sup>3</sup>General practice, UMCG, Groningen,

Netherlands, <sup>4</sup>BRAHMS GmbH, Thermo Fisher Scientific, Hennigsdorf,

Germany, <sup>5</sup>Internal Medicine, UMCG, Groningen, Netherlands.

**Background and aims:** Vasopressin is involved in volume homeostasis, but has been hypothesized to have also deleterious renal effects. In diabetic rodent

models vasopressin has indeed been shown to cause glomerular hyperfiltration, albuminuria and glomerulosclerosis. In humans the role of vasopressin in the progression of diabetic nephropathy has yet not been investigated. We studied the association of copeptin, a surrogate for vasopressin, with (change in) albuminuria and eGFR in a cohort of patients with diabetes mellitus, cross-sectionally and during follow-up.

**Materials and methods:** Included were patients with type 2 diabetes, treated in primary care and participating in two prospective cohorts from the ZODIAC study. Plasma copeptin was measured in baseline samples (Chemiluminescence Immunoassay), which were stored at  $-80^{\circ}\text{C}$ . Estimated GFR (MDRD) and urinary albumin/creatinine ratio (ACR) were measured annually. We used multivariate linear regression models to investigate the association between plasma copeptin and ACR increase and eGFR decrease, adjusting for gender, age, baseline ACR or eGFR, chronic kidney disease (CKD) risk factors (being: smoking, HbA1c, blood pressure, total cholesterol and body mass index) and the use of ACE-inhibition.

**Results:** Plasma samples of 1325 diabetes patients were available (44% male, age  $67 \pm 11.6$  yrs, ACR 16 (IQR 8.1-53.6)  $\text{mg/g}$ , eGFR  $65 \pm 15$   $\text{ml/min/1.73m}^2$ ). Baseline plasma copeptin level (5.2 (IQR 3.1 - 9.4)  $\text{pmol/L}$ ) was significantly associated with baseline ACR (standardized B 0.15,  $p<0.001$ ) and eGFR (std B -0.20,  $p<0.001$ ). These associations remained significant after adjustment for gender, age and CKD risk factors (std B 0.12,  $p<0.001$  and std B -0.25,  $p<0.001$  resp.). From this cohort, plasma samples and at least 3 years of follow-up were available in 1184 (89%) patients. These patients were followed for a median of 7.4 (5.9-9.9) years, during which a mean increase in ACR of 0.1  $\text{mg/g/year}$  and a mean decrease in eGFR of 1.2  $\text{ml/min/1.73m}^2/\text{year}$  occurred. Baseline plasma copeptin was significantly associated with rate of ACR increase and eGFR decline after adjustment for gender, age, and baseline ACR or eGFR (std. B 0.10,  $p$  0.02 and std. B -0.08,  $p$  0.01, resp.). These associations remained significant after adjustment for risk factors for CKD progression (std. B 0.09,  $p$  0.04 and std. B -0.07,  $p$  0.03, resp.). These associations were independent of baseline ACR and/or baseline eGFR. In the multivariate regression models the strength of the association of copeptin with either increase in ACR or decrease in eGFR was stronger than that of established risk factors for diabetic nephropathy such as smoking, BMI, blood pressure and HbA1c.

**Conclusion:** In diabetic patients a higher baseline copeptin concentration is significantly associated with an increase in ACR and a decline in eGFR during follow-up, independent of, and stronger than most traditional CKD risk factors. Therefore it would be interesting to study the effect of lowering vasopressin levels (e.g. by drinking more water) on the progression of chronic kidney disease in diabetic patients.

## 156

### Patients with diabetic kidney disease have a high frequency of bacterial infections

M. Lehto, R. Simonsen, V. Harjutsalo, C. Forsblom, P.-H. Groop, the FinnDiane Study Group;

Folkhälsan Research Center, Folkhälsan Institute of Genetics, Helsinki, Finland.

**Background and aims:** Diabetic nephropathy is commonly associated with chronic inflammation. Long disease duration and poor glycemic control increase the risk of bacterial infections in patients with diabetes. Frequent exposure to pathogen associated molecules (e.g. bacterial endotoxins, flagellin, peptidoglycans) may accelerate the development of diabetic complications, especially diabetic nephropathy. The specific aim of the present study is to assess the prevalence of bacterial infections in Finnish patients with type 1 diabetes (T1D) using the data from the national hospital and drug registries.

**Materials and methods:** For the study of bacterial infections, 4023 patients with T1D were selected from the FinnDiane Study. For comparison, we obtained from the Finnish Public Register Center ([www.vaestorekisterikeskus.fi](http://www.vaestorekisterikeskus.fi)) a large control population [10991 non-diabetic control (NDC) subjects], which were age- and sex-matched for the diabetic patients. Information about bacterial infections and antimicrobial drugs used for treatment of infections were collected from a 10-year period (1996-2005) from the Hospital Discharge Register (HILMO; [www.stakes.fi](http://www.stakes.fi)), and the National Drug Register (The Social Insurance Institution of Finland-KELA; [www.kela.fi](http://www.kela.fi)). Total number of follow-up years in non-diabetic controls and different diabetic subgroups were as follows: NDC\_subjects (109271 yrs), T1D\_normal AER (13023 yrs), T1D\_microalbuminuria (2242 yrs), T1D\_macroalbuminuria (3333 yrs), and T1D\_ESRD (2167 yrs). Statistical analyses were performed using SPSS 15.0 and SAS 9.2.

**Results:** T1D patients were diagnosed with various microbial infections 2.5–4.0 times more frequently than the NDC-subjects. Of all microbial infections, bacterial infections were more common in T1D patients compared to NDC-subjects (54 vs. 34%). Based on the total number of follow-up years, the frequency of bacterial infections increases in parallel with the stages of kidney disease [bacterial infections (n)/patient years]: 0.008 NDC-subjects (1.0x), 0.011 T1D patients with normal AER (1.3x), 0.021 T1D patients with microalbuminuria (2.5x), 0.034 T1D patients with macroalbuminuria (4.2x), and 0.237 ESRD (29.0x) [Cochran-Armitage (CA) Trend Test;  $p < 0.0001$ ]. T1D patients purchased antibiotics on average 2.3 times more frequently than NDC-subjects. The number of purchases increased in parallel with the stages of kidney disease [antibiotic purchases (n)/patient years]: 0.46 NDC-subjects (1.0x), 0.79 T1D patients with normal albuminuria (1.7x), 1.02 T1D patients with microalbuminuria (2.2x), 1.33 T1D patients with macroalbuminuria (2.9x), and 3.28 ESRD (7.1x) (CA Trend Test;  $p < 0.0001$ ). In diabetic patients, the number of antimicrobial purchases correlated positively with glycemic control.

**Conclusion:** Bacterial infections are more common in diabetic patients compared to age-matched non-diabetic controls. More importantly, bacterial infections are more frequently encountered in patients with diabetic nephropathy. Whether the bacterial infections are mere consequence or potential contributing factor to diabetic nephropathy has to be elucidated.

### Role of CD40 and its adaptors protein TRAF in obesity and obesity-associated complications

M. Poggi<sup>1,2</sup>, D. Engel<sup>2</sup>, L. Beckers<sup>2</sup>, E. Wijnands<sup>2</sup>, A. Driessen<sup>2</sup>, M.-C. Alessi<sup>1</sup>, N. Gerdes<sup>3</sup>, E. Lutgens<sup>4</sup>;

<sup>1</sup>Faculty of medicine, INSERM 1062/INRA 1260, Marseille, France, <sup>2</sup>Pathology, Cardiovascular Research Institute Maastricht (CARIM), Netherlands, <sup>3</sup>Poliklinik, Klinikum der Universität München, Ludwig-Maximilians-Universität München, Institut für Prophylaxe und Epidemiologie der Kreislauferkrankungen, Germany, <sup>4</sup>Medical Biochemistry, Academic Medical Center, Amsterdam, Netherlands.

**Background and aims:** Obese adipose tissue shows hallmarks of chronic inflammation, which promotes the development of metabolic disorders and cardiovascular complications such as insulin resistance and type2 diabetes. The mechanisms by which cells interact and the players involved are still unclear. We recently reported that CD40L deficiency prevents adipose tissue inflammation and metabolic manifestations of obesity in mice. Because of serious side-effect of CD40L treatment, our aim is to investigate the role of CD40 receptor and its associated signaling intermediates the TRAFs (TNF-receptor associated factors) in the development of obesity and associated complications.

**Materials and methods:** CD40<sup>+/+</sup>, CD40<sup>-/-</sup> or CD40<sup>-/-</sup> mice bearing a CD40 transgene under an MHCII promoter with or without mutations at the CD40-TRAF2/3/5, CD40-TRAF6 or both binding sites (CD40-TRAF2/3/5/6) were fed a 45% HFD for 18–20 week. Metabolic and inflammatory parameters were evaluated by glucose and insulin tolerance test, flow cytometry, RNA quantification, immunohistochemistry and ELISA.

**Results:** Conversely to CD40L deficiency, CD40-deficiency did not attenuate the development of obesity, but increased CD3<sup>+</sup> infiltration in adipose tissue and glucose intolerance. Absence of CD40-TRAF2/3/5/6 signalling accelerated the body weight gain. Body-weight-matched CD40-TRAF2/3/5/6 mice exhibited a higher insulin resistance and glucose intolerance than other genotypes. In their adipose tissue, pro-inflammatory T cell number was increased while Treg number was reduced. Hepatic steatosis was strongly aggravated in CD40-TRAF2/3/5/6 mice. A similar phenotype but less pronounced was observed when only CD40-TRAF2/3/5 signaling was defective. In contrast, absence of CD40-TRAF6 signalling did not aggravate the HFD-induced effects and even reduced the body weight gain and hyperglycaemia.

**Conclusion:** Unexpectedly, CD40 deficiency aggravates metabolic complications and inflammation associated with obesity. Absence of CD40-TRAF2/3/5 signaling amplifies the deleterious effect of high fat feeding, suggesting a protective role of this pathway. Modulate CD40-TRAF signaling could constitute a therapeutic target to improve obesity and insulin resistance.

### Complement C5a anaphylatoxin receptor (C5aR) contributes to macrophage accumulation and polarisation in adipose tissue inflammation

J. Phielers<sup>1</sup>, K.-J. Chung<sup>1</sup>, A. Chatzigeorgiou<sup>1</sup>, J.D. Lambris<sup>2</sup>, T. Chavakis<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine III and Institute of Physiology, Dresden University of Technology, Germany, <sup>2</sup>Department of Pathology and Laboratory Medicine, University of Pennsylvania, Philadelphia, USA.

**Background and aims:** Obesity is associated with chronic low-grade inflammation of adipose tissue (AT) and the development of insulin resistance and type 2 diabetes mellitus. In particular, accumulation of macrophages in the obese AT and their polarization into the M1 pro-inflammatory subtype plays a critical role in the development of insulin resistance. Complement is a versatile system involved in activation of innate immunity, inflammation and tissue remodeling. The central reactions in the complement cascade are the cleavage of C3 and C5 that leave behind the active anaphylatoxins C3a and C5a that act through their cellular G-protein-coupled receptors, C3aR and C5aR, and the opsonins C3b and C5b. Complement components have been implicated as regulators in AT inflammation, however, the exact

influence of the C5a-C5aR axis on the accumulation and activation of pro-inflammatory immune cells within the AT in the course of obesity is poorly characterized.

**Materials and methods:** We performed the high fat diet (HFD)-induced obesity model in mice sufficient or deficient in the C5aR. Therefore, 8–9 weeks old mice were fed a HFD or control normal diet (ND) for 20 weeks. Insulin resistance development was tested by i.p. glucose tolerance test (GTT) and i.p. insulin tolerance test (ITT) (week 16 or 17 of the feeding, respectively). Subcutaneous and peri-gonadal fat pads were excised, digested with collagenase and the stromal vascular fraction (SVF) was analyzed by fluorescence activated cell sorting (FACS). In addition, excised adipose tissues are currently analyzed by immunohistology and Western Blot.

**Results:** We found, that expression of C5aR was increased 10 times in subcutaneous and 100 times in gonadal AT of obese mice compared to lean mice. Moreover, the total weight gain upon HFD was not affected by C5aR-deficiency, however, obese mice lacking C5aR displayed improved glucose tolerance. This was associated with reduced AT inflammation due to C5aR deficiency. In particular, while the number of total leukocytes and infiltrated CD4<sup>+</sup> or CD8<sup>+</sup> T-cells did not differ between C5aR-sufficient and -deficient mice, we observed that the numbers of total macrophages and especially the proinflammatory M1 type (defined as F4/80+CD11b+CD11c<sup>+</sup> and / or F4/80+CD11c+CD206<sup>+</sup> cells) were significantly reduced ( $p < 0.05$ ) in C5aR<sup>-/-</sup> mice, as compared to WT controls. In addition, we could detect increased expression of the M2-derived anti-inflammatory cytokine IL-10 and reduced expression of proinflammatory cytokines such as TNF and IL-6 in C5aR-deficient animals ( $p < 0.05$ ).

**Conclusion:** These results suggest that the C5a-C5aR axis contributes to macrophage accumulation and polarization into M1 cells in the obese AT and thereby to insulin resistance development.

## 159

### Myeloid specific knockout of ADAM17 protects from diet induced insulin resistance and hepatic inflammation

V. Casagrande, A. Marino, M. Fabrizi, R. Menghini, R. Lauro, M. Federici; University of Tor Vergata, Medical School, Rome, Italy.

**Background and aims:** Tissue Inhibitor of Metalloprotease 3 (TIMP3), an endogenous regulator of metalloproteinases such as MMP9 and TNF- $\alpha$  Converting Enzyme (TACE, also named ADAM17), acts at the interface of inflammation and insulin resistance. Timp3 null mice fed a high fat diet (HFD) showed glucose intolerance, insulin resistance and macrovesicular steatosis compared with WT mice. Moreover, obesity is characterized by a deficiency of TIMP3 in liver and white adipose tissue (WAT), suggesting that downregulation of TIMP3 in metabolic tissue may contribute to the deregulation of inflammatory pathways. Reduced Timp3 expression results in uncontrolled ADAM17 protease activity increasing the level of circulating soluble TNF- $\alpha$ . On the other hand ADAM17 deficiency confers partial protection from HFD-induced insulin resistance, with positive effects on liver ability to resist to inflammatory effects of HFD. Here we test the effect of selective inhibition of ADAM17 in hepatocyte or myeloid cells on glucose metabolism and inflammatory status.

**Materials and methods:** To generate knockout animals we used the Cre/loxP strategy. We crossed mice expressing Cre recombinase under control of Albumin or Lysozyme2 promoters with mice that containing loxP sites flanking ADAM17 gene. ADAM17 hepatocytes (A17LKO) and myeloid cells (A17M-KO) knockout mice were confirmed by PCR analyses. WT (Adam17 Floxed), A17LKO and A17MKO mice fed standard chow or HFD were subjected to metabolic and molecular phenotypization.

**Results:** In the diet induced obesity model, after 16 weeks of HFD, we observed that A17LKO mice did not differ in weight from WT mice while A17MKO showed a reduced weight. Consistently, A17MKO mice compared with WT and A17LKO, showed a significant improved fasting glucose levels, glucose tolerance and insulin sensitivity, measured by intraperitoneal glucose tolerance test (IPGTT) and insulin tolerance test (IPITT). We analyzed ADAM17 expression in liver by Real-Time PCR and Western blot, and showed that ADAM17 levels were significantly decreased in both transgenic mouse models. Further analysis on isolated hepatic cells showed that ADAM17 mRNA was significantly reduced in hepatocytes but not in non-parenchymal cells from A17LKO mouse livers. Moreover, there was a reduction of ADAM17 mRNA levels in CD11b<sup>+</sup> isolated cells from A17MKO mouse liver. Western blot analysis on liver extracts revealed that JNK1/2 were less phosphorylated in A17MKO compared to A17LKO and controls. In liver mRNA expression profiling for lipogenic and inflammatory genes revealed

that A17MKO mice had significant lower levels for TNF- $\alpha$ , CCL2 and CD68, ChREBP and SCD1.

**Conclusion:** Our data indicate that the myeloid specific ADAM17 deletion protects from HFD induced insulin resistance and hepatic inflammation.

## 160

### TimP3 modulates immune cell activation in a model of metabolic inflammation

V. Marchetti, M. Fabrizi, M. Cavallera, M. Mavilio, V. Casagrande, R. Menghini, R. Lauro, M. Federici; Internal Medicine, University of Rome Tor Vergata, Italy.

**Background and aims:** Activation of inflammatory pathways contributes to the beginning and the development of both atherosclerosis and type-2 diabetes. Among other cytokines, tumour necrosis factor (TNF) is central to the initiation and orchestration of innate immunity and recruitment of circulating leukocytes and dendritic cells to inflamed sites. TNF- $\alpha$  converting enzyme (TACE) mediates TNF shedding and is selectively inhibited by the tissue inhibitor of metalloproteinase 3 (TIMP3). Decreased expression of TIMP3 results in insulin resistance and inflammation while a TACE inhibitor improves insulin sensitivity and vascular inflammation. Here, we investigate whether TIMP3 affects inflammatory cells phenotype elucidating their function during the progression of metabolic dysfunction.

**Materials and methods:** We evaluated the effects of TIMP3 deficiency on systemic and tissue leukocytes and their state of activation in mice, under conditions of high fat diet (HFD) (1–4 months). Leukocytes were isolated from blood and stromal vascular cell (SVC) fraction of white adipose tissue (WAT) and characterized by flow cytometry antibodies direct against CD11c, CX3CR1, F4/80, and CD206 antigens. Real Time PCRs were engaged in order to evaluate and quantify the expression of pro and anti-inflammatory genes in SVC of WT and TIMP3KO mice after the HFD treatment. The level of circulating pro and anti-inflammatory mediators was studied using a panel of 60 cytokines.

**Results:** The total number of circulating F4/80<sup>+</sup>, F4/80<sup>+</sup> CX3CR1<sup>+</sup>, CX3CR1<sup>+</sup>, CX3CR1<sup>+</sup>CD11c<sup>+</sup> was found increased in TIMP3KO mice compared to the WT animals at 3 months of HFD treatment (1.9, 3.8, 2.3, 2.9 fold increase respectively,  $p < 0.001$ ), while CD11c<sup>+</sup>CD206<sup>+</sup> cells were found decreased in KO animals compared to WT mice (1.8 fold change,  $p < 0.001$ ). TIMP3KO, compared to WT, revealed early signs of glucose intolerance after 2/3 months of HFD and were overtly hyperglycaemic at glucose tolerance test, independently from body weight ( $p < 0.01$ ), at 4 months of HFD. F4/80<sup>+</sup>CX3CR1<sup>+</sup>, CX3CR1<sup>+</sup>CD11c<sup>+</sup>, CX3CR1<sup>+</sup>CD11c<sup>-</sup> cells were significantly increased in the SVC of TIMP3 KO mice compared to WT under HFD for 4 months. Several proinflammatory genes, distinctive of macrophage M1 and dendritic cells were significantly up regulated in the SVC of TIMP3 KO mice compared to the WT mice (MGL1, IFN- $\gamma$ , IL1 $\beta$ , CX3CR1 and CX3CL1), while genes of M2 macrophage line were undetectable in the SVC of TIMP3 mice compared to SVC of WT animals (IL-10, YM1). The level of proinflammatory cytokines was significantly upregulated in the serum of TIMP3 KO mice compared to the serum of WT mice (IL-6, MIP1- $\alpha$  and - $\gamma$ , IL-8).

**Conclusion:** We have identified one population of F4/80<sup>+</sup>CX3CR1<sup>+</sup> macrophages and CD11c<sup>+</sup>CX3CR1<sup>+</sup> dendritic cells (DCs) that are upregulated along the HFD condition in the blood and SVC component of TIMP3KO mice. How these myeloid cells participate in inflammatory signals in adipose tissue is not completely known. Because myeloid cells accumulation and resident macrophage polarization is a critical event regulated by TIMP3 for the coordination of inflammatory events within fat tissue, increasing its release from cells directly at tissue injury site may be a valid approach for decreasing inflammatory signals in adipose tissue.

## 161

### The phenotype of infiltrating macrophages influences arteriosclerotic plaque vulnerability in the carotid artery

K. Cho, T. Kondo, T. Atsumi, H. Miyoshi; Department of Medicine II, Hokkaido University Graduate School of Medicine, Sapporo, Japan.

**Background and aims:** Macrophages located in the wall of the artery accumulate excess lipid, become foam cells and contribute to atherosclerotic

plaque development. Continued accumulation of lipid by foam cells is associated with an inflammatory response and increased plaque vulnerability. Vulnerable plaques are less stable and associated with major cardiovascular events. Obesity is known to cause a reduction in M2 macrophages (anti-inflammatory) in adipose tissue and an increase in the numbers of M1 macrophages (inflammatory) which have been likened to foam cells. However, there are limited studies investigating the relationship between macrophage polarity (M1 vs M2) and the vulnerability of human atherosclerotic plaques. Therefore, we examined the nature of the macrophage and factors associated with arteriosclerosis using the plaques obtained in carotid endarterectomy (CEA) for stenosis of internal carotid artery.

**Materials and methods:** This study was approved by the ethics and clinical research committee. Patients were provided an overview of the study procedures and informed consent was obtained from eligible patients prior to enrollment in the study. Patient eligibility was determined using criteria described by the North American Symptomatic Carotid Endarterectomy Trial (NASCET) and Japanese Guidelines for the Management of Stroke. An Echocardiogram of the carotid artery was performed in all patients prior to surgery. Plaques were removed from 65 patients via CEA and immediately processed for later analysis by immunohistochemistry, western blotting, and real time-PCR. Patient medical records were obtained from the hospital for additional information regarding medical history and recent blood chemistry data to see related risk factors for atherosclerosis.

**Results:** Patients were divided into two groups, those suffering from cerebral infarction (symptomatic,  $n=35$ ) and those that did not present with symptoms (asymptomatic,  $n=30$ ). Age, sex, BMI, medical history, medication status, blood chemistry, and carotid stenosis were not significantly different between groups. Echocardiogram analysis revealed that plaque vulnerability was greater in the symptomatic group ( $p=0.033$ ,  $\chi^2$ -square test). Analysis by immunohistochemistry demonstrated that plaques from the symptomatic group had a greater concentration of M1 macrophages (CD68, CD11c positive) while plaques from the asymptomatic group had more M2 macrophages (CD163 positive). This observation was confirmed by Western blotting. Further characterized was performed by real time-PCR and we observed that plaques from the symptomatic group had increased expression of the M1 markers CD68 (3.7-fold) and CD11c (3.3-fold), as well as MCP-1 (3.4-fold), IL-6 (9.6-fold), and MMP-9 (10.6-fold) as compared to the asymptomatic group.

**Conclusion:** Here we report that the M1/M2 macrophage activation previously described in adipose tissue was also observed in human arteriosclerotic plaques of the carotid artery. Furthermore our data suggest that macrophage polarity/activation is associated with plaque vulnerability.

anti-CXCL10 treated mice. CXCL10 positive  $\beta$ -cells were found in HFD but not in ND or anti-CXCL10/HFD treated mice. In line with this, mRNA levels of IL-1 $\beta$  and CXCL10 in isolated islets were highly up-regulated (15-fold,  $p<0.05$ ) in HFD treated mice, which was inhibited in anti-CXCL10 treated mice. CXCL10 mRNA was 5-fold up-regulated in epididymal fat and normalized by anti-CXCL10. It was also upregulated in the liver, but in contrast, in the hypothalamus, neither CXCL10 nor IL-1 $\beta$  was changed in HFD or anti-CXCL10 treated mice. The protective effects of anti-CXCL10 were also confirmed in human islets. The cytokine mixture IL-1 $\beta$ /IFN- $\gamma$  highly induced IL-1 $\beta$  production and secretion of IL-1 $\beta$ , which was inhibited by anti-CXCL10, possibly through a negative feedback mechanism. In parallel, cytokine-induced apoptosis was also inhibited.

**Conclusion:** Our results show that CXCL10 antagonism improved  $\beta$ -cell survival and function and support a potential role for CXCL10 in the treatment of diabetes.

## 162

### CXCL10 antagonism improves insulin sensitivity, inflammation, beta cell function, survival and mass

P. Shah<sup>1</sup>, E. Domsgen<sup>1</sup>, J. Bergemann<sup>1</sup>, P. Janssen<sup>1</sup>, N. Stappenbeck<sup>1</sup>, P. Cardarelli<sup>2</sup>, K. Maedler<sup>1</sup>;

<sup>1</sup>Centre for Biomolecular Interactions, University of Bremen, Germany,

<sup>2</sup>Medarex Inc., Bristol-Myers Squibb R&D, Sunnysvale, USA.

**Background and aims:** Sub-clinical inflammation participates in the pathophysiology of type 2 diabetes (T2DM) and leads to  $\beta$ -cell failure and impaired function. The pro-inflammatory chemokine CXCL10 is expressed in islets in T1DM and T2DM and leads to  $\beta$ -cell apoptosis and impaired function mediated through TLR4 signaling. In the present study we investigated whether CXCL10 antagonism improves glycemia,  $\beta$ -cell function and survival in vivo in mice and in vitro in human islets.

**Materials and methods:** C57BL/6J mice were fed a high fat/high sucrose diet (HFD) for 16 weeks and treated with an antibody to CXCL10 or with control IgG twice weekly. Glucose and insulin tolerance were monitored every 4 weeks, pancreas, liver, adipose tissue and hypothalamus were isolated and analyzed by IHC and RT-PCR after 16 weeks.

**Results:** A murine CXCL10 antibody prevented diabetes progression in C57BL/6J mice fed a high fat/high sucrose diet (HFD) for 16 weeks. Anti-CXCL10 improved glucose tolerance, insulin sensitivity and glucose stimulated insulin secretion. HFD feeding reduced stimulatory index by 2.8-fold, but anti-CXCL10 treatment completely restored GSIS. While anti-CXCL10 treated mice showed a 1.8-fold increased  $\beta$ -cell mass compared to normal diet (ND) controls,  $\beta$ -cells were unable to compensate for the higher insulin demand in response to the HFD in vehicle treated mice. Analysis of  $\beta$ -cell apoptosis showed an induction of TUNEL-positive  $\beta$ -cells in the HFD mice compared to ND mice (0.2% vs. 0.05%,  $p<0.05$ ), which did not occur in the

**Insulin resistance is associated with macroangiopathy in type 1 diabetic patients treated with intensive insulin therapy from the onset of the disease**

A. Araszkiwicz, A. Uruska, S. Pilacinski, D. Naskret, B. Wierusz-Wysocka, D. Zozulinska-Ziolkiewicz;  
Department of Internal Medicine and Diabetology, Poznan University of Medical Sciences, Poland.

**Background and aims:** The aim of the study was to evaluate the relationship between insulin resistance and the early marker of macroangiopathy such as intima-media thickness (IMT) in patients with type 1 diabetes, treated from the initial diagnosis with intensive insulin therapy.

**Materials and methods:** The study group consisted of 79 patients with type 1 diabetes (51 men, 28 women) from the Poznan Prospective Study (PoProStu), aged  $37.2 \pm 6.2$  years, with mean HbA1c from 13 years of follow  $8.3 \pm 1.3\%$ . IMT of the right common carotid artery was determined using high resolution ultrasonography (Accuscan Cv 70, Siemens, Erlangen, Germany) with 10-MHz transducer. Two longitudinal projections were assessed (anterolateral and posterolateral). Images were captured at 16 frames per second for 5 s. The distal 1 cm of the common carotid artery just proximal to the bulb was measured and calculated automatically with the Carotid Analyzer for Research (CAD 5) program. Insulin resistance was assessed on the basis of anthropometric data and estimated glucose disposal rate (eGDR) with cut-off point  $7.0 \text{ mg/kg/min}$ . Patients with  $\text{eGDR} < 7.0 \text{ mg/kg/min}$  were defined as insulin resistant.

**Results:** Patients with  $\text{eGDR} < 7.0 \text{ mg/kg/min}$  ( $n=27$ , 36%) had significantly higher IMT [ $0.63(0.55-0.72)$  vs  $0.55(0.50-0.58) \text{ mm}$ ,  $p=0.004$ ]. A significant positive correlation with IMT was revealed for body mass ( $r=0.26$ ,  $p=0.025$ ), BMI ( $r=0.28$ ,  $p=0.015$ ), waist circumference ( $r=0.34$ ,  $p=0.003$ ), WHR ( $r=0.24$ ,  $p=0.041$ ) and negative correlation was observed for  $\text{eGDR}$  ( $r=-0.44$ ,  $p<0.0001$ ). In multiple linear regression model low  $\text{eGDR}$  was associated with increased IMT ( $\beta -0.40$ ,  $p=0.003$ ). The association was independent from duration of diabetes, sex and LDL (low density lipoproteins) concentration.

**Conclusion:** The lower insulin sensitivity the higher IMT in patients with type 1 diabetes, treated from the initial diagnosis with intensive insulin therapy.

**Early detection of atherosclerosis in asymptomatic patients with type 1 diabetes (concordance between single-photon emission computed tomography, calcium score and carotid ecography)**

E. Aguilera<sup>1</sup>, M. Milà<sup>2</sup>, S. Serrano<sup>3</sup>, E. Bernal<sup>3</sup>, E. Pizarro<sup>4</sup>, I. Olaizola<sup>1</sup>, E. Serra<sup>1</sup>, E. Guanyabens<sup>1</sup>, M. Puig-Domingo<sup>1</sup>;

<sup>1</sup>Endocrinology and Diabetes Unit, Hospital Universitari Germans Trias i Pujol, Badalona, Barcelona, <sup>2</sup>Nuclear Medicine Unit, Hospital Universitari Germans Trias i Pujol, Badalona, Barcelona, <sup>3</sup>Cardiology Unit, Hospital Universitari Germans Trias i Pujol, Badalona, Barcelona, <sup>4</sup>Endocrinology and Diabetes Unit, Hospital de Mataró, Spain.

Type 1 diabetes mellitus (T1D) is associated with an increase in cardiovascular disease, although there are few data on the prevention and screening of these patients. Different studies have demonstrated the functional and structural vascular changes produced in early stages of the evolution of T1D. Carotid artery intima-media thickness (cIMT) is a marker of atherosclerosis which is correlated with coronary disease. Multiple slice computerized tomography (CT) allows anatomical images of the coronary arteries to be non-invasively obtained by the quantification of calcification (calcium score). Myocardial perfusion imaging with single-photon emission computed tomography (SPECT) is commonly used to identify patients with coronary artery disease.

**Aim:** Evaluate the presence of early atherosclerosis in asymptomatic T1D patients with an evolution of more than 10 years and no history of ischemic or macrovascular heart disease, compared with non-diabetic age and sex matched controls.

**Material and methods:** 109 T1D patients consecutively recruited from the outpatient clinic were studied (61 males; age:  $38.2 \pm 8.2$  years,  $21.2 \pm 8.3$  years of T1D evolution; BMI:  $25.1 \pm 3.6 \text{ kg/m}^2$ , HbA1c:  $7.9 \pm 1.1\%$ ; total cholesterol  $182.8 \pm 23.9 \text{ mg/dl}$ ; HDL  $60.4 \pm 15.2 \text{ mg/dl}$ , LDL  $105.9 \pm 21.6 \text{ mg/dl}$ ; 52% non-smokers; 28% retinopathy; 11% microalbuminuria) and 44 non-diabetic controls age and sex matched were studied. Carotid ecography was performed to determine the mean cIMT (common carotid, bifurcation and right and left internal) and the presence of atheroma plaques. A high resolution multidetector CT with ECG was undertaken for calcium analysis and quantification. In T1D patients an SPECT myocardial was also performed.

**Results:** In T1D patients the mean cIMT was significantly greater compared with controls ( $0.56 \pm 0.14$  vs.  $0.48 \pm 0.14 \text{ mm}$   $p=0.004$ ). Patients with atheroma plaques (13/109) presented a significantly higher HbA1c ( $8.7 \pm 0.9\%$  vs.  $7.8 \pm 1.1\%$   $p=0.003$ ) and a greater mean cIMT than patients without plaques ( $0.53 \pm 0.11 \text{ mm}$  vs.  $0.75 \pm 0.14 \text{ mm}$   $p=0.001$ ). Patients with a calcium score  $> 0$  (22/109) displayed a significantly higher age and HbA1c ( $44.5 \pm 5.1$  vs.  $36.7 \pm 8.1$  years  $p=0.001$  and  $8.5 \pm 1.1$  vs.  $7.8 \pm 1.0\%$   $p=0.003$ ), a longer evolution of the disease ( $25.4 \pm 9.2$  vs.  $19.3 \pm 7.4$  years  $p=0.005$ ) and a greater mean cIMT ( $0.53 \pm 0.11 \text{ mm}$  vs.  $0.67 \pm 0.18 \text{ mm}$ ,  $p=0.001$ ) compared to patients with score of 0. In the control group the percentage of subjects with plaques (3/44: 6.8%) and score  $> 0$  (5/44: 11.3%) was lower than in T1D patients. 13/109 T1D patients showed an abnormal SPECT (6 patients presented ischemia and 7 a pathological decline in cardiac ejection fraction after exercise). However, there was a low concordance between calcium score, carotid ecography and SPECT (only 2 patients presented plaques and an score  $> 0$ ).

**Conclusion:** A considerable percentage of our T1D patients with more than 10 years of disease evolution presented data suggestive of atherosclerosis, thus the inclusion of non-invasive screening methods for the detection of early atherosclerosis should be considered in routine clinical practice.

**The significant influence of integration of glycaemic control on skin AF value through retrospective and prospective studies in patients with type 1 diabetes**

S. Hoshina, J. Miura, E. Sugisawa, H. Kobayashi, M. Osawa, Y. Uchigata;  
Diabetes center, Tokyo Women's Medical University, Japan.

**Background and aims:** It is known that Advanced Glycation Endproducts (AGEs) participates in the development and the progression of the diabetic microvascular complications. Recently Autofluorescence (AF) reader (AGE Reader<sup>®</sup>; DiagnOptics Inc.) which could measure skin AF value in the skin non-invasively was developed. We have reported that skin AF values positively correlated with the progression of the diabetic complications. However, it is not clear what term of glycemic control influenced skin AF value and if change of glycemic control influenced skin AF value in the future. Therefore, we retrospectively investigated the correlation between skin AF values and glycemic control in the past 15 years, and prospectively studied that the relationship between the change of glycemic control and later skin AF value.

**Materials and methods:** We recruited 241 type 1 diabetes patient (Male/Female: 132/109) that regularly visit our hospital, aged  $37 \pm 10$  years old, duration of diabetes  $18.1 \pm 10$  years. Skin AF value was measured on inner side of right forearm on AGE Reader<sup>®</sup>. We measured blood glucose, HbA1c, lipid and blood pressure on the same time. In the retrospective study, we calculated the area under the curve (AUC) of HbA1c every 3 months for 15 years. In prospective study, we could followed 73 patients on skin AF value every 6 months for 2 years. The change of skin AF was defined that increasing 0.1 or more was increasing skin AF group and decreasing 0.1 or more was decreasing group and change less than 0.1 was invariant group.

**Results:** Skin AF value at the enrollment positively correlated with current age, duration of diabetes, HbA1c, LDLc and log ACR ( $R=0.28$ ,  $p=0.002$ ;  $R=0.42$ ,  $p<0.0001$ ;  $R=0.52$ ,  $p<0.0001$ ;  $R=0.22$ ,  $p=0.036$ ;  $R=0.27$ ,  $p=0.01$ , respectively). In retrospective study, the skin AF was strongly correlated with the past HbA1cAUC going back to 15 years (5 years,  $R=0.35$ ,  $p<0.0001$ ; 10 years,  $R=0.36$ ,  $p<0.0001$ ; 15 years,  $R=0.55$ ,  $p<0.0001$ ). In the prospective study, 25/74 patients belonged to increasing, invariant and decreasing groups after 2 years, respectively. Skin AF value was  $2.6 \pm 0.6$  in increase group and  $2.2 \pm 0.6$  in decrease group after 2 year. Skin AF values at 2 years later were not correlated with HbA1c, lipid profile at the time of enrollment and duration of diabetes. Skin AF values at 2 years later were not correlated with HbA1cAUC during 6, 12, 18 and 24 months after registration in all patients (6 months  $R=0.182$ ,  $p=0.124$ ; 12 months  $R=0.169$ ,  $p=0.153$ ; 18 months  $R=0.160$ ,  $p=0.175$ ; 24 months  $R=0.171$ ,  $p=0.149$ ), however, weakly correlated with

HbA1cAUC during 6, 12, 18 and 24 months in decreasing group (6 months  $R=0.37$ ,  $p=0.017$ ; 12 months  $R=0.35$ ,  $p=0.023$ ; 18 months  $R=0.33$ ,  $p=0.035$ ; 24 months  $R=0.33$ ,  $p=0.036$ ). In multivariate regression analysis, skin AF value at 2 years later was most correlated with duration of diabetes duration ( $\beta=0.023$ ,  $p=0.000$ ). Concerning diabetic microvascular complications, 9 patients developed one stage of retinopathy and 5 patients developed one stage of nephropathy. There were no significant difference in skin AF value at the enrollment and change of skin AF value for 2 years between progression group and other group both in retinopathy and nephropathy.

**Conclusion:** The skin AF value was strongly correlated with past HbA1cAUC for more than 5 years. In prospective study, HbA1cAUC for 2 years did not strongly influence on later skin AF value and longer-term observation will be needed.

## 166

### Influence of age at diagnosis over the glycaemic control evolution in type 1 diabetes

L. Forga<sup>1</sup>, M.J. Goñi<sup>1</sup>, D. Mozas<sup>1</sup>, B. Ibañez<sup>2</sup>, K.I. Cambra<sup>2</sup>, J.P. Martínez<sup>1</sup>;

<sup>1</sup>Navarra Hospital Complex, <sup>2</sup>Centro de Investigación Biomédica de Navarra, Pamplona, Spain.

**Background and aims:** The most important factor in order to reach a good metabolic control in type 1 diabetes is a tailored insulin treatment, but some other factors can influence the glycaemic control long after the diagnosis. One of these factors is the age of onset. In patients <20 years of age, the oldest, especially during adolescence have poor glycaemic control. In adults, there are no studies dealing with the relationship between the age of diagnosis and subsequent metabolic control. The aim of this study is to know the effect of age of diagnosis over glycaemic control measured as HbA1c along of follow-up.

**Materials and methods:** This is an observational retrospective follow-up study. The subjects of the study are all patients with type 1 diabetes with onset from 1990 to 2008 that have been treated in our hospital. Patients with LADA were excluded. Information about their HbA1c levels and other clinical parameters were gathered at onset and along the follow-up (until 2010) at a yearly basis. To assess the evolution of HbA1c since the disease onset and the relationship between age at onset and calendar year, we used General Additive Models (GAM) and linear models, with patients' annual HbA1c levels as response variable, and the number of years since the onset together with the age at onset as covariates. This study was approved by the regional Ethics Review Board of our Community.

**Results:** Mean (SD) follow-up was 10.1 (5.3) years, and ranged from 2 (those with onset in 2008) to 20 years (those with onset in 1990). The total number of participants has been 716, 280 with onset under 15 yrs of age and 436 with onset above this age. The proportion of men was slightly higher than the women. Children diagnosed at ≤4 years of age, at the beginning had higher HbA1c levels than the other children under 15. From the third year since onset and afterwards, the evolution of children 0–4 and 5–9 was very similar. Patients with onset between 10 and 14 had a different graph, their HbA1c level at the beginning was similar to the patients aged 5 to 9, but then it rose to reach 8.4% after seven years and then made a plateau. Their final HbA1c levels were lower than the other children groups. In adults, patients diagnosed between 15 and 29 had a rapid increase in the HbA1c level during the four first years and then they made a plateau at 8%. The group with diagnosis between 30 and 44 years had the lowest level of HbA1c at onset, but then it increased slowly and reached 8% level eight years after the diagnosis. Then, the glycaemic control impairment followed. Finally, patients diagnosed between 45 and 60 years had the worst HbA1c levels all the time, from the beginning to the end of the study.

**Conclusion:** 1) The age of diagnosis is related to the glycaemic control evolution in type 1 diabetes 2) Patients aged 10–14 have different behavior than the two other children groups. 3) In adults, patients aged 15–29 and 30–44 show a contrary evolution in their metabolic control during follow-up and 4) patients over 45 have the poorest glycaemic control.

### Subcortical volume loss in type 1 diabetes patients relates to cognitive dysfunction

E. van Duinkerken<sup>1</sup>, R.G. IJzerman<sup>1</sup>, M.M. Schoonheim<sup>2</sup>, M. Klein<sup>3</sup>, F.J. Snoek<sup>3</sup>, F. Barkhof<sup>2</sup>, M. Diamant<sup>1</sup>;

<sup>1</sup>Diabetes Center / Department of Internal Medicine, <sup>2</sup>Department of Radiology, <sup>3</sup>Department of Medical Psychology, VU University Medical Centre, Amsterdam, Netherlands.

**Background and aims:** Type 1 diabetes mellitus (T1DM) is associated with cognitive dysfunction, most notably in patients with microangiopathy. Decrements in performance are particularly seen in domains of processing and motor speed, and attention. These cognitive defects are only weakly associated with global and regional cortical grey matter volume changes in T1DM patients. Hitherto, no studies have assessed the effect of T1DM and microangiopathy on deep grey matter structures and their relation with cognition. Therefore, we assessed subcortical structures in patients with and without microangiopathy and controls and determined the relationship with cognitive dysfunction.

**Materials and methods:** Fifty patients with, 53 without microangiopathy and 47 controls were included in this study. All underwent a multi-sequence MRI-scan on a 1.5T Siemens Sonata (Erlangen, Germany) and a detailed neuropsychological assessment covering general cognitive ability, memory, information processing speed, executive, attentional, motor and psychomotor performance. Using a T1-based magnetization prepared rapid acquisition gradient echo (MPRAGE), subcortical structures were segmented by using FMRIB's Integrated Registration and Segmentation Tool (FSL4.1.5 FIRST). Bilaterally, the nucleus accumbens and caudatus, amygdala, hippocampus, pallidum, putamen, thalamus, and the brainstem were segmented. Mean volume per participant was normalised for head size, to allow group comparison.

**Results:** Patients with microangiopathy were oldest, had higher HbA1c, systolic blood pressure, depressive symptoms and performed worse on cognitive tests involving general cognitive ability, information processing and motor speed, and attention. To reduce statistical tests, all deep grey matter structures were entered in 1 MANCOVA, corrected for age, gender, systolic blood pressure, depressive symptoms and HbA1c. The overall F-test was significant ( $F=1.61$ ;  $P=0.027$ ) allowing post-hoc testing. After Bonferroni correction, this revealed volume loss in the bilateral nucleus accumbens, putamen and thalamus in patients with microangiopathy versus controls (all  $P<0.04$ ). Lower volume in those without microangiopathy relative to controls was borderline significant for the left nucleus accumbens and thalamus, and bilateral putamen (all  $P<0.08$ ). In all patients higher volume of the above mentioned structures was positively related with general cognitive ability, information processing and motor speed ( $r_{\text{max}}=0.3$ ; all  $P<0.04$ ).

**Conclusion:** We found lower volume in the bilateral nucleus accumbens, putamen and thalamus in patients with microangiopathy, which were marginally significant in those without microangiopathy. As these structures, and especially the thalami, have many connections with other (sub)cortical structures, involvement in speed tasks is not surprising, and may indicate that these deep grey matter structures play an important role in T1DM related cognitive dysfunction. Further longitudinal studies should determine the course of these changes, of their interrelationship and the clinical impact. ### Increased mortality in autoimmune diabetes in adults

L. Olsson<sup>1</sup>, A. Ahlbom<sup>1</sup>, T. Andersson<sup>1</sup>, V. Grill<sup>2</sup>, K. Midtthjell<sup>3</sup>, S. Carlsson<sup>1</sup>;

<sup>1</sup>Department of epidemiology, Karolinska Institutet, Stockholm, Sweden,

<sup>2</sup>Department of Cancer Research and Molecular Medicine, the Norwegian University of Science and Technology, Trondheim, <sup>3</sup>Department of Community Medicine and General Practice, the Norwegian University of Science and Technology, Levanger, Norway.

**Background and aims:** Knowledge on mortality in autoimmune diabetes with adult onset is limited. Our aim was to analyse the risk of all-cause mortality, and mortality from cardiovascular disease (CVD) and ischemic heart disease (IHD) in autoimmune diabetes in adults compared to individuals without diabetes and individuals with type 2 diabetes.

**Materials and methods:** We used information from 61,613 individuals without diabetes, 208 cases of autoimmune diabetes in adults (anti-GAD positive and diagnosed at age ≥35 years) and 2,425 cases of type 2 diabetes (anti-GAD

negative and diagnosed at age  $\geq 35$  years) who in 1995–1997 participated in the Norwegian Nord-Trøndelag Health Study (consisting of questionnaires and clinical examinations) and who were followed in the Norwegian national cause of death registry until 2009. Hazard ratios (HR) with 95% CI for all-cause, CVD and IHD mortality were calculated using Cox proportional hazards models.

**Results:** Autoimmune diabetes in adults was associated with an increased risk of all-cause (HR 1.56, 95% CI 1.26–1.93), CVD (1.89, 1.42–2.52) and IHD mortality (HR 2.44, 1.61–3.73), similar to the increased mortality risks observed in type 2 diabetes; HR 1.43 (95% CI 1.33–1.53) for all-causes, HR 1.73 (1.58–1.90) for CVD and HR 2.17 (1.91–2.47) for IHD. The excess mortality was seen in both men and women and was not explained by overweight, lifestyle or socioeconomic position. In autoimmune diabetes, mortality was primarily observed in cases with HbA1C  $\geq 6.5\%$ ; HR 2.79 (95% CI 1.78–4.39) vs. HR 1.33 (95% CI 0.33–5.33) for IHD mortality.

**Conclusion:** Autoimmune diabetes in adults is associated with increased mortality risk, primarily from CVD, of similar magnitude as type 2 diabetes. The increased risk is associated with glycaemic control, rather than with traditional risk factors. These results emphasise the importance of correct treatment to improve survival in autoimmune diabetes in adults.

### A strategy for combining minor genetic susceptibility genes to improve prediction of disease in type 1 diabetes

C. Winkler<sup>1,2</sup>, J. Krumsiek<sup>3</sup>, J. Lempainen<sup>1,4</sup>, P. Achenbach<sup>1,2</sup>, H. Grallert<sup>5</sup>, E. Giannopoulos<sup>1,2</sup>, M. Bunk<sup>1,2</sup>, F.J. Theis<sup>3</sup>, E. Bonifacio<sup>6,2</sup>, A.G. Ziegler<sup>1,2</sup>;

<sup>1</sup>Institute of Diabetes Research, Helmholtz Zentrum München, Klinikum rechts der Isar, Technische Universität München, Neuherberg, Germany, <sup>2</sup>Forschergruppe Diabetes e.V., Neuherberg, Germany, <sup>3</sup>Institute of Bioinformatics and Systems Biology, Helmholtz Zentrum München, Neuherberg, Germany, <sup>4</sup>Immunogenetics Laboratory, and Department of Pediatrics, University of Turku, Finland, <sup>5</sup>Research Unit of Molecular Epidemiology, Helmholtz Zentrum München, Neuherberg, Germany, <sup>6</sup>Center for Regenerative Therapies, Dresden University of Technology, Germany.

**Background and aims:** Genome-wide association studies have identified gene regions associated with the development of type 1 diabetes (T1D). With the exception of the HLA and the INS gene regions, T1D susceptibility associated with any single loci is relatively small and these single gene regions have provided relatively little improvement in disease prediction. Aim of this study was to determine whether and how the combined allele frequency of non-HLA susceptibility genes can stratify islet autoimmunity and/or T1D risk in children with *a priori* familial diabetes risk.

**Material and methods:** The single nucleotide polymorphisms (SNPs) in 12 T1D susceptibility gene regions (*ERBB3*, *PTPN2*, *IFIH1*, *PTPN22*, *KIAA0350*, *CD25*, *CTLA4*, *SH2B3*, *IL2*, *IL18RAP*, *IL10*, *COBL*) were analyzed in 1290 children from the German BABYDIAB study, a prospective observational study that follows offspring of mothers or fathers with T1D from birth for the development of islet autoantibodies and T1D (median follow-up, 14 years). The sum of the scores for the 12 genes was assigned as the combined risk score for each child. Children were classified by their total number of risk alleles and risk stratification models developed.

**Results:** Receiver Operator Curves analysis was performed for all possible 4095 gene combinations. Overall, gene combinations were more effective in discriminating T1D than islet autoimmunity ( $P < 0.0001$ ) and most effective in children with an *a priori* high risk HLA genotype ( $P < 0.0001$ ). Highest discrimination (AUC, 0.73;  $P < 0.00001$ ) was obtained by the sum of risk alleles for 8 genes (*IFIH1*, *CTLA4*, *PTPN22*, *IL18RAP*, *SH2B3*, *KIAA0350*, *COBL*, *ERBB3*) using T1D as outcome in the HLA risk children. Categorizing risk allele score from these 8 genes in low, moderate and high (scores:  $< 6$ ,  $6-9$ ,  $> 9$ ) was able to stratify the risk for developing islet autoantibody (by age 14 years: low scores 0%; moderate scores 20%; high scores 37%;  $P = 0.001$ ) and for progression from islet autoantibody positivity to T1D (by age 10 years: moderate scores 40%; high scores 80%  $P = 0.03$ ). Overall T1D risk by age 14 years ranged from 0% in HLA risk children with low risk allele scores to 26.9% (95% CI, 15.2–38.6%;  $P < 0.0001$ ) in children with high risk allele scores.

**Conclusion:** Genotyping at multiple susceptibility T1D loci in children from affected families can identify neonates with sufficient risk to be considered for early intervention.

### New genetic loci associated with increased urinary albumin excretion rate in subjects with type 1 diabetes

N.K.A. Sandholm<sup>1,2</sup>, V.-P. Mäkinen<sup>1,3</sup>, C. Forsblom<sup>1,3</sup>, V. Harjutsalo<sup>1,4</sup>, M. Parkkonen<sup>1,3</sup>, L.M. Thorn<sup>1,3</sup>, J. Wadén<sup>1,3</sup>, M. Saraheimo<sup>1,3</sup>, B. He<sup>5</sup>, A.-M. Österholm<sup>3</sup>, K. Tryggvason<sup>5</sup>, P.-H. Groop<sup>1,3</sup>, FinnDiane Study Group; <sup>1</sup>Folkhälsan Institute of Genetics, Helsinki, Finland, <sup>2</sup>Department of Biomedical Engineering and Computational Science, Aalto University School of Science, Espoo, Finland, <sup>3</sup>Division of Nephrology, Helsinki University Central Hospital, Finland, <sup>4</sup>Dept Chronic Disease Prevention, National Institute for Health and Welfare, Helsinki, Finland, <sup>5</sup>Dept Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden.

**Background and aims:** Diabetic nephropathy is a major complication of diabetes and is often first manifested by the detection of an abnormal urinary

albumin excretion rate (AER). AER in diabetes is known to have an inherited component, but the associated genetic variants remain unknown. The aim of this study is to detect common genetic variation associated with elevated AER in patients with type 1 diabetes (T1D).

**Materials and methods:** This study includes 1925 subjects from the Finnish Diabetic Nephropathy (FinnDiane) Study who have T1D duration at least 10 years and have 24h AER measurements and genome-wide association study (GWAS) data available. Patients with either end-stage renal disease, or T1D duration below 15 years and persistent normoalbuminuria, were excluded. Genotypes for 550,000 single nucleotide polymorphisms were obtained from a GWAS performed on 3652 T1D subjects, and were extended to 2.4 million SNPs after imputation (MACH software, HapMap II CEU reference population). AER was  $\log_{10}$  transformed and analysed as a continuous trait to better describe the variation of the phenotype. As the use of anti-hypertensive medication strongly affects the AER, subjects with ( $n=1002$ ) and without ( $n=923$ ) anti-hypertensive medication were analysed separately. Linear regression was performed with PLINK software and the models were adjusted for sex, age at onset of T1D, duration of T1D, and the ten first principal components calculated with EIGENSTRAT software. The association results of the two groups were subsequently combined together with fixed effect meta-analysis.

**Results:** Five SNPs on chromosome 4q34 were genome-wide significantly ( $P<5\times 10^{-8}$ ) associated with elevated AER (smallest  $P=1.5\times 10^{-9}$ ). Furthermore, a total of 62 genetic regions reached  $P<1\times 10^{-4}$  and were selected for follow-up genotyping in order to detect further possible loci associated with elevated AER. Additional genotyping is currently ongoing in 3300 T1D subjects with Caucasian origin. Gene enrichment analysis conducted with MAGENTA software indicated that the association analysis results were enriched with genes involved in natural killer cell mediated immunity. **Conclusion:** We have identified a locus on chromosome 4q34 that is genome-wide significantly associated with high AER in T1D, as well as 62 putative susceptibility loci for high AER with  $P<1\times 10^{-4}$ . Replication in other T1D cohorts will tell whether these loci harbor true susceptibility genes for high AER or not.

<sup>2</sup>Division of RI Laboratory, Biomedical Research Center, Saitama Medical

University, <sup>3</sup>Department of Metabolism/Diabetes and Clinical Nutrition,

Nagasaki University Hospital of Medicine and Dentistry, <sup>4</sup>Department of Endocrinology, Metabolism and Diabetes, Kinki University School of Medicine, Osaka, <sup>5</sup>Third Department of Internal Medicine, Interdisciplinary Graduate School of Medical and Engineering, University of Yamanashi,

<sup>6</sup>Department of Internal Medicine, Saitama Social Insurance Hospital,

<sup>7</sup>Department of Internal Medicine, Saiseikai Central Hospital, Tokyo,

<sup>8</sup>Department of Diabetes and Metabolism, Iwate Medical University, Morioka, Japan.

**Background and aims:** A number of novel non-HLA type 1 diabetes (T1D) susceptibility loci have been identified in Caucasians based on genome-wide association studies using common SNPs, whereas rare resistant variants have been identified in IFIH1. We previously reported the associations of INS, CTLA4, IL2RA, ERBB3 and CLEC16A with Japanese T1D. In the present study, we analyzed rare variants of the T1D candidate genes.

**Materials and methods:** We analyzed 706 T1D patients and 863 control subjects in Japan; the mean age at onset was 31.5 years. First, by next-generation sequencing, we screened 24 candidate genes, including IFIH1, WFS1 and GLIS3, in 96 T1D patients and 96 control subjects to identify any variations of the exons. Four DNA pools (2 x 48 patients and 2 x 48 controls) were prepared, and all exons of the 24 genes were PCR-amplified, then the DNA samples were mixed and sequenced with an Illumina Genome Analyzer IIx. The obtained sequence reads were mapped to the genes to identify variations. We next assessed their association in a large number of subjects recruited from the collaborating institutions.

**Results:** In total, 57 non-synonymous SNPs (nsSNPs) were discovered in 18 genes of the 24 genes studied. Approximately two-thirds of the identified nsSNPs appeared to be rare variants (MAF  $<0.05$  in control subjects). Among them, we further analyzed rare variants in IFIH1 and GLIS3. Three rare vari-

ants, R705S, N930S and rs3573203 (IVS14+1), were identified in IFIH1; two of which (R705S and N930S) have not yet been reported in Caucasians. The T allele of the rare rs3573203, reported to be associated with T1D resistance in Caucasians, did not significantly decrease in the T1D patients, although the MAF in the control subjects was higher in Japanese than in Caucasians (0.0351 vs 0.0093). The R705S and N930S variants were not significantly associated with T1D. Regarding GLIS3, four rare variants, H669R, S738F, A753V and R763H, were identified. The frequencies of these rare variants were all lower in the T1D patients in comparison to the controls, and A753V was significantly associated with resistance to T1D (absent in the T1D patients vs 0.0070 in the controls,  $P=0.0008$ ).

**Conclusion:** In the present study, a rare variant in GLIS3 was found to be protective against T1D. GLIS3, highly expressed in pancreatic beta cells, encodes a zinc finger transcription factor, which directly regulates insulin gene expression. The precise mechanism responsible for the association is unclear, but the variant may affect autoimmunity to insulin or to the GLIS3 protein itself.

## 172

### Comprehensive evaluation of type 2 diabetes susceptibility loci in the Japanese population by using 1000 genomes project data

H. Kazuo<sup>1</sup>, F. Hayato<sup>1</sup>, T. Johnson<sup>2</sup>, T. Yamauchi<sup>1</sup>, S. Maeda<sup>2</sup>, T. Tsunoda<sup>2</sup>, Y. Nakamura<sup>2</sup>, T. Kadowaki<sup>1</sup>

<sup>1</sup>University of Tokyo, <sup>2</sup>RIKEN, Yokohama, Japan.

**Background and aims:** Although over 50 type 2 diabetes (T2D) loci have been identified through genome-wide association studies (GWAS), the vast majority of the genetic predisposition to T2D still remains to be clarified. One explanation is that despite the use of high-throughput genotyping arrays, only a small proportion of genetic variants in the human genome are actually surveyed, especially in non-European populations.

**Materials and methods:** We explored the comprehensive catalog of genomic variations provided by the 1000 Genomes Project to identify variations conferring susceptibility to T2D in the Japanese population that were not detected in the previous scans. We imputed 10,524,368 variants derived from 286 East Asian subjects (November 2010 Release) in 5,976 cases and 20,829 controls genotyped by 610K single-nucleotide polymorphism (SNP) array.

**Results:** Overall concordance was good, although imputed SNPs with minor allele frequency (MAF) below 1% apparently contained poorly imputed SNPs. We then tested associations for T2D before and after adjusting for age, sex, and body mass index. We found that in addition to variants of the previously reported loci there were 25 loci harboring multiple variants with a p-value lower than  $10^{-5}$ . The MAF range was 0.01 to 0.45, and the odds ratios were between 1.10 and 1.48. We are conducting a replication study to confirm the association in another 7,000 cases and 3,500 controls. We also sought to define the most relevant SNPs for susceptibility to T2D in the previously identified genes. We did not find any stronger association with T2D than the originally reported SNPs in our population. However, there is a tendency that lower frequency variants were enriched in those with large effect size.

**Conclusion:** Our study highlights the benefits of using data derived from next-generation sequencing of the human genome such as the 1000 Genomes Project to explore T2D loci more comprehensively.

## 173

### The association of the mitochondrial DNA 16184-16193 poly-C variant with type 2 diabetes

C. Langenberg<sup>1</sup>, Z. Ye<sup>1</sup>, C. Gillson<sup>1</sup>, M. Plotka<sup>2</sup>, K.-T. Khaw<sup>3</sup>, J. Poulton<sup>2</sup>, N.J. Wareham<sup>1</sup>

<sup>1</sup>MRC Epidemiology Unit, Cambridge, <sup>2</sup>University of Oxford, <sup>3</sup>Department of Public Health and Primary Care, University of Cambridge, UK.

**Background and aims:** The association between the mitochondrial DNA 16181-16193 polycytosine (poly-C tract) that maps precisely to the OriB origin of replication, also known as the OriB or 16189 variant, and type 2 diabetes (T2D) has not been reliably characterized with studies providing conflicting results. We performed a meta-analysis of results from a large new case-control study and the published evidence to systematically investigate the association between the 16189 variant and T2D.

**Materials and methods:** We genotyped the 16189 variant by pyrosequencing followed by Sanger cycle sequencing for all individuals with a homopolymeric C-tract sequence  $\geq 10$  in the Norfolk Diabetes Case-Control Study (NDCCS), which comprised 5,419 T2D cases and 6,738 population-based

controls. We performed a systematic review identifying all studies of the 16189 variant and T2D published prior to September 2011. We used random effects meta-analysis methods to combine results from 19 published studies and the NDCCS including a total of 16,060 T2D cases and 17,783 controls, and examined potential sources of heterogeneity.

**Results:** In a combined analysis, the pooled odds ratio for T2D of the 16184-16193 poly-C tract was 1.31 (95% confidence interval (CI): 1.18–1.46). Sample size and ethnic background of study participants were identified as significant sources of heterogeneity between studies. Analyses restricted to larger studies with 500 or more T2D cases showed an odds ratio of 1.15 (95% CI: 1.05–1.25). In ethnic-group stratified analyses, the odds ratio for the association of the 16189 variant with T2D was 1.10 (95%CI: 1.01–1.20) in Europeans and 1.49 (95%CI: 1.27–1.74) in Asians.

**Conclusion:** Results from this systematic review and meta-analysis suggests that the mitochondrial DNA 16184-16193 poly-C tract is associated with an increased risk of type 2 diabetes.

## 174

### Functional analysis of GCKR mutations identified in subjects with hypertriglyceridaemia demonstrates the inherent challenges in clinical interpretation of rare variants

A. Raimondo<sup>1</sup>, M.G. Rees<sup>1,2</sup>, J. Wang<sup>3</sup>, A. Barrett<sup>1</sup>, F.S. Collins<sup>2</sup>, R.A. Hegele<sup>3</sup>, A.L. Gloyne<sup>1,4</sup>

<sup>1</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, UK, <sup>2</sup>National Human Genome Research Institute, National Institute of Health, Bethesda, USA, <sup>3</sup>Robarts Research Institute, University of Western Ontario, London, Canada, <sup>4</sup>Oxford NIHR Biomedical Research Centre, Churchill Hospital, UK.

**Background and aims:** The clinical interpretation of rare non-synonymous variants identified via sequencing projects is currently a major challenge. GCKR encodes glucokinase regulatory protein (GKRP), a predominantly nuclear protein that inhibits hepatic glucokinase (GCK). This inhibition is modulated by fructose-1-phosphate (F1P) and fructose-6-phosphate (F6P). Recent genetic and functional studies have demonstrated that GCKR variants across the allelic spectrum have effects on glucose and lipid levels, but the clinical interpretation of rare variants identified in patients with extreme lipid phenotypes has not been explored. The aim of this study was to use an established suite of functional assays to determine the cell biological and biochemical attributes of twelve non-synonymous GCKR variants identified in individuals with hypertriglyceridaemia, hypothesising that these variants would show functional characteristics distinct from those identified in individuals with less extreme phenotypes.

**Materials and methods:** All twelve variants were transiently transfected into HeLa cells as fluorescent fusion plasmids and analysed for their subcellular localisation relative to wild type (WT) GKRP. Nine variants were expressed and purified from *E. coli* and assayed for their ability to inhibit glucose-stimulated GCK activity in the presence and absence of F1P and F6P. *In silico* analysis of all variants was assessed using SIFT and PolyPhen 2.

**Results:** Of the twelve GCKR variants studied, nine, including M344I, showed nuclear localisation and expression levels similar to that of WT GKRP. Three variants, including R259W, showed near-complete loss of nuclear localisation. Kinetic characterisation of nine variants, selected on the basis of their proximity to conserved sugar binding motifs, demonstrated that four showed altered kinetics. R259W GKRP showed reduced GCK inhibition ( $p < 0.001$  compared to WT GKRP) and significantly decreased interaction with both F6P ( $p < 0.001$ ) and F1P ( $p < 0.05$ ). M344I GKRP showed no difference in response to F6P ( $p > 0.1$ ) but exhibited reduced GCK inhibition and interaction with F1P ( $p < 0.001$ ). R259W and M344I showed the largest loss of response to F6P and F1P, respectively, of any human variant GKRP tested to date. *In silico* analysis did not provide a consensus on the predicted pathogenicity of the majority of the twelve variants, including M344I.

**Conclusion:** Our results indicate that GCKR variants that contribute to hypertriglyceridaemia cause substantial functional defects. Individual variants differ in their cellular and kinetic effects, supporting the need to assess both when evaluating the pathogenicity and clinical significance of rare GCKR variants.

## OP 30 Beta cell function in vivo

### 175

#### Hepatocyte-derived factor(s) drive beta cell hyperplasia in insulin resistant mice

A. El Ouaamari, D. Kawamori, E. Dirice, C. Liew, J. Shadrach, J. Hu, H. Katsuta, J. Hollister-Lock, A. Wagers, R. Kulkarni; Joslin Diabetes Center, Boston, USA.

Inter-organ communication controls key aspects of energy homeostasis and its dysregulation may underlie metabolic disorders such as diabetes. Islet  $\beta$ -cell hyperplasia occurs as an adaptive response to physiological (pregnancy) or pathophysiological (obesity) insulin resistant states. To test the hypothesis that cross-talk between liver and pancreatic islets mediates  $\beta$ -cell growth in response to insulin resistance, we used the Liver-specific Insulin Receptor Knockout (LIRKO) mouse, a unique model that exhibits a dramatic islet hyperplasia. To explore whether circulating factors in LIRKO mice promote  $\beta$ -cell proliferation, we established *in vivo* transplantation and parabiotic mouse models and assessed  $\beta$ -cell replication by bromodeoxyuridine incorporation. We also cultured mouse or human islets for 48 hours in serum LIRKO or controls, followed by confocal microscopic evaluation of  $\beta$ -cell growth by Ki67 immunostaining. Our studies reveal that: (1) control mice parabiosed to LIRKO mice show a 4-fold increase in  $\beta$ -cell mitosis and (2) control islets transplanted under the kidney capsule in LIRKO mice exhibit 7-fold increased  $\beta$ -cell proliferation. Furthermore, LIRKO serum enhanced  $\beta$ -cell proliferation in primary mouse islets, control human islets, and in islets from a patient with type 2 diabetes. Finally, culturing mouse islets in conditioned media from liver explants (LECM) or hepatocytes (HCM) for 24 h enhanced  $\beta$ -cell growth respectively. Taken together, these data indicate the existence of circulating, non-neural and non-cell autonomous  $\beta$ -cell growth factors, and strongly implicate the liver as a critical source of these novel  $\beta$ -cell growth factor(s). The enhanced proliferation observed in  $\beta$ -cells from both control and diabetic humans underscores the significance of our model to identify the putative  $\beta$ -cell growth factor(s) with the long term goal of increasing  $\beta$ -cell number in patients with diabetes.

#### Melatonin receptor 2 (MT2) knock-out mice display increased insulin release

C.L.F. Nagorny Holmberg<sup>1</sup>, H. Bennet<sup>2</sup>, L. Shcherbina<sup>3</sup>, M. Fex<sup>2</sup>, N. Wierup<sup>3</sup>, H. Mulder<sup>1</sup>

<sup>1</sup>Molecular Metabolism, <sup>2</sup>Diabetes and Celiac Disease, <sup>3</sup>Neuroendocrine Cell Biology, Clinical Sciences Malmö, Sweden.

**Background and aims:** Numerous independent studies have confirmed our initial finding that a variant of the melatonin receptor 1B (*MTNR1B* (MT2)) gene is associated with increased fasting plasma glucose, impaired early insulin secretion, and Type 2 Diabetes Mellitus (T2DM). Both melatonin receptors are expressed in human islets. Given the increased mRNA expression of *MTNR1B* in islets of individuals carrying the risk variant, the pathogenetic effects could be exerted via a direct inhibitory effect of melatonin on  $\beta$ -cells. This is based on the notion that melatonin, in most studies, appears to inhibit insulin secretion. To address this hypothesis, we examined glucose homeostasis *in vivo* and *in vitro* in mice lacking the *MTNR1B*/MT2 receptor.

**Materials and methods:** Whole body female knock out mice for the MT2 receptor were kindly provided by Professor David Weaver. IVGTTs as well as hyperinsulinemic-euglycemic clamps were performed to investigate  $\beta$ -cell function and whole body glucose metabolism in mice at 12 weeks of age. The number of islets and  $\beta$ -cell mass were investigated by immunohistochemistry and morphometry (12–14 weeks, male). Static 1 h incubations of isolated islets were performed in 12 week old female mice. Statistical analysis was by Student's *t*-tests; mean  $\pm$  standard errors of the mean (SEM) are given.

**Results:** After intravenous injection of glucose MT2 mice showed lower plasma glucose (AUC: MT2: 556.7  $\pm$  37.3; WT: 694.1  $\pm$  54.5; arbitrary units (AU);  $p=0.057$ ) as well as elevated insulin (AUC: MT2: 205.2  $\pm$  28.1; WT: 91.2  $\pm$  6.1 AU;  $p<0.02$ ). This was also reflected by the acute insulin response (AIR; MT2: 86.3  $\pm$  14.2; WT: 21.7  $\pm$  3.1;  $p<0.02$ ). Glucose elimination (K: %/min) was not different in MT2 and WT mice. The clamp revealed an insulin-resistant phenotype in MT2 mice. The glucose infusion rate was lower in MT2 (MT2: 5.5  $\pm$  1.3; WT: 10.9  $\pm$  1.8 mg/kg/min;  $p=0.03$ ), while hepatic glucose

production during the clamp was higher (MT2:  $1.0 \pm 1.6$ ; WT:  $-6.0 \pm 2.1$  mg/kg/min;  $p < 0.02$ ). There was no difference in islet size, but the number of islets was increased in MT2 (MT2:  $2.5 \times 10^{-6} \pm 3.2 \times 10^{-7}$ ; WT:  $1.3 \times 10^{-6} \pm 1.7 \times 10^{-7}$  AU;  $p < 0.01$  (Mann Whitney, U-test)), resulting in an increased  $\beta$ -cell mass. *In vitro* batch incubations agreed with *in vivo* data: MT2 islets showed improved glucose-stimulated insulin secretion (GSIS) (MT2:  $4.5 \pm 0.3$ ; WT:  $3.0 \pm 0.2$  (Fold change over basal ng/islet/h);  $p < 0.001$ ).

**Conclusion:** The hyperinsulinemic phenotype of the MT2 mice *in vivo* and *in vitro* confirms our genetic data, where the risk genotype displayed decreased first phase insulin secretion and decreased glucose tolerance due to a possible gain of function mutation. Our mice, having a loss of function, display the opposite phenotype: they release more insulin and tolerate glucose better after an intravenous glucose challenge. The reduced insulin sensitivity during the clamp may be an adaptation to this improved capacity to secrete insulin.

### The GLP-1-gastrin dual agonist ZP3022 increases beta cell mass via an increase in mean islet mass in db/db mice

D.L.C. Almholt<sup>1</sup>, L.S. Dalbøge<sup>2</sup>, J.L. Tolborg<sup>1</sup>, C. Grøndahl<sup>1</sup>, K. Fosgerau<sup>1</sup>, T.S.R. Neerup<sup>1</sup>;

<sup>1</sup>Pharmacology, Zealand Pharma A/S, Glostrup, <sup>2</sup>Gubra ApS, Hørsholm, Denmark.

**Background and aims:** Combination treatment of diabetic db/db mice with exendin-4 and gastrin has previously been shown to preserve beta-cell mass by stimulating beta-cell growth and differentiation. Here we investigate the effects of a novel and potent GLP-1-gastrin receptor dual agonist (ZP3022, invented by Zealand Pharma A/S) that acts on the GLP-1 and CCKB (gastrin) receptors.

**Materials and methods:** Equimolar doses ( $2 \times 50$  nmol/kg/day) of ZP3022, liraglutide, or vehicle were administered by twice daily subcutaneous injection to male db/db mice for 2, 4 or 8 weeks. HbA1c and fasting blood glucose levels were determined at treatment start and at termination. Pancreata were removed and fixed in phosphate buffered formaldehyde for stereological determination of beta-cell mass. Furthermore, the total number of islets, mean islet mass, and number of proliferating beta cells (insulin and ki67 double immunoreactive cells) were determined stereologically in the 8 weeks treatment groups.

**Results:** After 2, 4, and 8 weeks of treatment, both ZP3022 and liraglutide caused a significant improvement in glycemic control as measured by HbA1c (8 weeks: Vehicle,  $7.4 \pm 0.5\%$ ; Liraglutide,  $5.3 \pm 0.4\%$ ; ZP3022,  $5.6 \pm 0.6\%$ ,  $p < 0.001$  for ZP3022 and liraglutide vs. vehicle) as well as fasting blood glucose levels. Both ZP3022 and liraglutide caused a significant increase in beta-cell mass compared to vehicle following 4 weeks of treatment (Figure,  $p < 0.05$ ). However, after 8 weeks of treatment, only ZP3022 resulted in a significant increase in beta-cell mass, compared to both vehicle- and liraglutide-treated mice (Figure,  $p < 0.001$  and  $p < 0.05$ , respectively). Following 8 weeks of treatment, neither the liraglutide- nor the ZP3022-treated groups showed any difference in the total number of islets compared to vehicle. In contrast, the mean islet mass was significantly increased in the ZP3022-treated group compared to vehicle ( $p < 0.01$ ). Finally, the total number of proliferating (ki67 positive) beta cells was significantly increased compared to vehicle in both the liraglutide- ( $p < 0.05$ ) and the ZP3022-treated ( $p < 0.001$ ) groups.

**Conclusion:** The study demonstrates that treatment of db/db mice with the GLP-1-gastrin receptor dual agonist ZP3022 causes a sustained improvement in glycemic control accompanied by an increase in the beta-cell mass. In contrast, liraglutide displays a transient effect on beta-cell mass. Moreover, it is demonstrated that the increased beta-cell mass is related to an increased proliferation of beta cells and an increased mean islet mass.

## 178

### Metreleptin therapy in leptin-deficient patients with lipodystrophic syndromes: effects on insulin secretion

C. Vatiér<sup>1,2</sup>, S. Fetita<sup>3</sup>, P. Boudou<sup>4</sup>, C. Tchankou<sup>5</sup>, L. Deville<sup>6</sup>, J.-F. Gautier<sup>7,3</sup>, C. Vigouroux<sup>1,2</sup>;

<sup>1</sup>INSERM UMRS\_938, <sup>2</sup>UPMC Université Paris 06, <sup>3</sup>Service de diabétologie et d'Endocrinologie, AP-HP Hôpital Saint-Louis, <sup>4</sup>Service de Biochimie et d'Hormonologie, AP-HP Hôpital Saint-Louis, <sup>5</sup>AP-HP Hôpital Saint-Louis, <sup>6</sup>Pharmacie, AP-HP Hôpital Saint-Louis, <sup>7</sup>INSERM UMRS\_872, Paris, France.

**Background and aims:** Lipodystrophic syndromes (LD) are genetic or acquired diseases characterized by total or partial body fat loss with severe alterations of lipid and glucose homeostasis. Although major insulin resistance is the prominent metabolic feature in LD, leading to severe difficulties to control diabetes, the progressive deterioration of glucose control is also linked to insulin secretion defects. The correction of leptin deficiency associated with LD has been shown to improve insulin sensitivity by decreasing hepatic and muscular lipotoxicity. However, only a few studies have investigated its effects on insulin secretion. We took advantage of a compassionate program of recombinant methionyl human leptin (metreleptin) therapy in patients with LD complicated with diabetes to study the effects of metreleptin on insulin secretion.

**Materials and methods:** Fifteen non HIV-infected patients with LD and leptin deficiency (4 generalized and 11 partial) are currently treated by a daily subcutaneous metreleptin injection ( $0.04$  to  $0.12$  mg/kg/d), gracefully supplied through a compassionate program authorized by the French Health Regulatory Agency (AFSSAPS). A favorable effect of metreleptin on glycemic control was defined as (1) a 0.5-point decrease in HbA1c, or (2) HbA1c stability with a decrease of  $>20\%$  in insulin doses or  $>50\%$  in oral antidiabetic drugs doses or discontinuation of one antidiabetic drug class, between treatment initiation (D0) and last visit. The first phase of insulin secretion was evaluated by (1) the Insulinogenic Index from 0 to 30 min of an Oral Glucose Tolerance Test ( $\Delta$  insulinemia (0-30) /  $\Delta$  glycemia (0-30)) at D0, after 30 days (M1, 10 patients) and one year (M12, 6 patients) of treatment, and (2) the acute insulin response to glucose (AIR) measured during a hyperglycemic clamp, at D0 and after one year of therapy (M12, 7 patients).

**Results:** Fourteen patients were studied (one patient interrupted her treatment), with a follow-up of  $15.4 \pm 9.6$  months (mean  $\pm$  SD). At the last visit, glycemic control was improved in 11 patients; weight loss was  $3.4 \pm 3$  kg; nine of the 12 patients with hypertriglyceridemia and 9 of the 11 patients with elevated liver enzymes at D0 significantly improved these alterations after metreleptin therapy. The Insulinogenic Index significantly increased in 8 of 10 patients at M1 and in 4 of 6 patients at M12 (median increase 374.7% range 86.3-1709.5,  $p = 0.04$  and 149.1% range 43.5-399%,  $p = 0.03$  at M1 and M12, respectively). AIR increased in 6 of 7 patients at M12 (median increase 246.1% range 96.6-900%,  $p = 0.07$ ). The 2 patients who had the better improvement of insulin secretion had the same genetic disease (AGPAT2 mutation) and the metabolic response to metreleptin was greater in patients with general-

ized lipodystrophy syndrome. The patients who did not improve their insulin secretion had partial lipodystrophy.

**Conclusion:** These results suggest that improvement of insulin secretion contributes to the metabolic efficiency of metreleptin therapy in most patients with lipodystrophic syndromes and diabetes.

### Lowering GIP secretion has beneficial role in reducing obesity and insulin resistance without impairing glucose tolerance and osteogenesis

D. Nasteska, N. Harada, S. Yamane, K. Suzuki, A. Hamasaki, E. Joo, K. Sasaki, K. Shibue, T. Harada, Y. Nakamura, N. Inagaki;

Department of Diabetes and Clinical Nutrition, Kyoto University, Japan.

**Background and aims:** Incretin hormones, such as gastric inhibitory polypeptide (GIP) and glucagon-like peptide-1 (GLP-1), represent the backbone of the enteroinsular axis. GIP has pancreatic and extrapancreatic effects implicated in beta cells function, bone formation and adipose tissue modification. Previous animal studies have shown changes occurring in absence of GIP receptor signalling, but knowledge regarding reduced GIP secretion remains insufficient. Hence, we have generated GIP-deficient mice with reduced and lacking GIP secretion.

**Materials and methods:** We generated GIP-deficient mice with truncated GIP gene. 9-weeks old wild type (WT), GIP-gene reduced, heterozygous mice (GIP<sup>+/-</sup>) and GIP-gene lacking, homozygous mice (GIP<sup>-/-</sup>) underwent oral glucose tolerance test (OGTT) in which blood glucose, insulin and GIP levels were measured. Furthermore, islets were isolated and assessed for insulin release during glucose and GIP stimulation. GIP-receptor (GIPR) levels were assessed by semiquantitative RT-PCR. In addition, tibiae were isolated and prepared for bone histomorphometry assessment. Another set of these groups of mice was kept on control diet (with 10% of fat) and high-fat diet (with 60% of fat) for 8 weeks, starting from 8 weeks of age. Afterwards, OGTT and insulin tolerance test (ITT) were performed. Finally, total body fat was measured by CT scan.

**Results:** During OGTT, GIP<sup>+/-</sup> mice showed significantly decreased GIP levels (~50%) compared to WT. In GIP<sup>-/-</sup> mice, GIP levels were below detectable range. Insulin levels at 15 min of OGTT were significantly lower in GIP<sup>+/-</sup> and GIP<sup>-/-</sup> mice compared to WT. Islets from GIP<sup>+/-</sup> and GIP<sup>-/-</sup> mice showed increased insulin secretion upon stimulation by 11.1 mM glucose and GIP similarly to WT islets. No statistical significance of GIPR mRNA expression occurred in pancreatic islets among all groups. Bone histomorphometry revealed that in GIP<sup>+/-</sup> mice bone volume, trabecular number and thickness, and osteoclast surface did not statistically differ compared to WT. In GIP<sup>-/-</sup> mice, however, bone volume, trabecular number and thickness were significantly decreased while osteoclast surface was statistically increased. OGTT after high-fat diet showed no significant changes in blood glucose levels between WT and GIP<sup>+/-</sup> mice whereas GIP<sup>-/-</sup> mice had significant increase compared to WT. GIP<sup>+/-</sup> and GIP<sup>-/-</sup> mice had significantly lower insulin levels than WT. ITT showed significant improvement of insulin sensitivity in GIP<sup>+/-</sup> and GIP<sup>-/-</sup> mice compared to WT. Total body fat was significantly decreased in GIP<sup>+/-</sup> mice (1.3-fold) compared to WT; GIP<sup>-/-</sup> mice had significantly lowest total body fat. Expression levels of GIPR in white and brown adipose tissue in GIP<sup>+/-</sup> mice were similar to those in WT while GIP<sup>-/-</sup> mice showed significant increase compared to WT.

**Conclusion:** Reduced GIP secretion, as shown in our GIP<sup>+/-</sup> mice model, does not seem to affect the function of GIPR in beta cells, or bone formation and volume. During metabolic stress, such as high-fat diet feeding, decreased GIP levels lead to decrease in insulin secretion and fat accumulation in adipose tissue without impairing glucose tolerance. These results suggest that lowering GIP secretion may have beneficial role in reducing obesity without impairing the other functions of GIP.

### The effect of decreased insulin sensitivity and insulin secretion on cerebrospinal fluid insulin level: an analysis in normoglycaemic patients with Alzheimer's disease

M.V. Macesic<sup>1</sup>, N.M. Lalic<sup>1</sup>, V.S. Kostic<sup>2</sup>, A. Jotic<sup>1</sup>, E. Stefanova<sup>2</sup>, K. Lalic<sup>1</sup>, T. Milicic<sup>1</sup>, L. Lukic<sup>1</sup>, N. Rajkovic<sup>1</sup>, J. Seferovic-Mitrovic<sup>1</sup>, J. Stanarcic<sup>1</sup>;

<sup>1</sup>Clinic for endocrinology, <sup>2</sup>Clinic for neurology, Belgrade, Serbia.

**Background and aims:** Previous studies have shown that impairment in insulin sensitivity and insulin secretion play the important role in pathogenesis

of Alzheimer's disease (AD), together with the effect of the peripheral hyperinsulinemia on cerebrospinal fluids (CSF) insulin level. However, the relationship between decreased insulin sensitivity and insulin secretion with CSF insulin level in patients with AD has not yet been clarified. This study was aimed to evaluate correlation of possible changes in insulin sensitivity and insulin secretion capacity with CSF insulin level in normoglycemic patients with AD.

**Materials and methods:** The study included 63 normoglycemic patients with AD (group A; BMI: 24.73 +/- 0.78 kg/m<sup>2</sup>, age: 71.32 +/- 7.54 years), and 27 healthy matched controls (group B; BMI: 25.04 +/- 0.69 kg/m<sup>2</sup>, age: 64.56 +/- 6.83 years). Insulin sensitivity was estimated using euglycemic hyperinsulinemic clamp method, total glucose uptake (M value) was calculated as the amount of glucose infused during steady state period (80-120 min); acute insulin response (AIR) was calculated as the average increase in insulinemia compared to the basal value in the first 8 min of intravenous glucose tolerance test, plasma and CSF insulin level were determined by radioimmunoassay and plasma adiponectin level by ELISA.

**Results:** Evaluation of the insulin sensitivity assessment has shown significantly higher levels of insulin resistance (IR) in group A compared to group B (M value; A: 6.39 +/- 0.52; B: 8.18 +/- 0.56 mg/min/kg, p<0.01). Also, parameter of early-phase of insulin secretion, AIR, were significantly lower in group A compared to group B (A: 20.26 +/- 2.77; B: 67.19 +/- 5.30 mU/l, p<0.01). Simultaneously, basal plasma insulin levels were higher in group A vs group B (A: 15.63 +/- 1.78; B: 7.42 +/- 0.77 mU/l, p<0.01), while the plasma adiponectin levels were significantly lower in group A vs B (A: 15.23 +/- 0.75; B: 18.59 +/- 2.06 ng/ml, p<0.01). In addition, in group A, insulin sensitivity index, expressed as M value, significantly correlated with CSF insulin level (r=0.908, p<0.01), whereas no correlations were detected between insulin secretion and CSF insulin level (r=0.002, p=ns). However, we found the significant correlation among M value, AIR and CSF insulin level (p=0.001, p=0.038, respectively, R<sup>2</sup>=0.805, p<0.001).

**Conclusion:** Our results have demonstrated decreased both insulin sensitivity and insulin secretion level in normoglycemic patients with AD, as well as relationship with CSF insulin level. These results also imply that insulin resistance might exert its pathogenic effect on the occurrence of AD through hyperinsulinemia and decreased adiponectin level.

## OP 31 The importance of glycaemic control: results from large scale studies

### The association of HbA<sub>1c</sub> with risk of cardiovascular hospitalisations and all-cause mortality is U-shaped

G.A. Nichols<sup>1</sup>, S. Gotlib<sup>2</sup>, S. Parasuraman<sup>2</sup>;<sup>1</sup>Kaiser Permanente Center for Health Research, Portland, <sup>2</sup>AstraZeneca LP, Wilmington, USA.

**Background and aims:** A recent analysis of the UK General Practice Research Database found that both low and high mean glycosolated hemoglobin (HbA<sub>1c</sub>) values were associated with increased all-cause mortality and cardiac events. The objective of our study was to determine whether these findings could be confirmed in a US population

**Materials and methods:** The study site was Kaiser Permanente Northwest, a group model health maintenance organization located in the Northwestern United States that provides comprehensive medical care to approximately 475,000 members. Using electronic medical record data, we identified 26,636 members with type 2 diabetes and no known prior cardiovascular hospitalization. Beginning in 2002, we identified the earliest date patients had HbA<sub>1c</sub>, systolic blood pressure, and low density lipoprotein cholesterol measurements within 6 months of each other as the index date and followed them until they died, disenrolled, or 31 December 2010. The outcomes, analyzed separately, were a hospitalization with a 1st listed diagnosis of cardiovascular disease (CVDh) and all-cause mortality. We used mean HbA<sub>1c</sub> values between the index date and outcome or end of follow-up to stratify patients into levels of HbA<sub>1c</sub> control (<6%, 6-6.4%, 6.5-6.9%, 7-7.4%, 7.5-7.9%, 8-8.4%, 8.5-8.9%, ≥9%). We estimated incidence rates of CVDh and mortality independently associated with these strata, adjusted for age, sex, and duration of diabetes. We then constructed Cox regression models to estimate the hazard ratios for the strata controlling for age, sex, race, diabetes duration, blood pressure, lipids, comorbidities, body mass index, smoking, and prescription pharmacotherapy.

**Results:** Over mean (SD) follow-up of 5.6 (2.5) years, 7.3% of the total sample experienced a CVDh and 10.9% died. Adjusted CVDh incidence was lowest among patients with mean HbA<sub>1c</sub> 7.0-7.4% (9.3/1000 person-years, 95% CI 8.3-10.4) and was significantly higher among patients with mean HbA<sub>1c</sub> <6% (12.8, 11.1-14.7), 8.5-8.9% (14.3, 11.8-17.3) and ≥9% (17.9, 15.5-20.7). Mortality rates displayed a similar relationship, with the lowest rate occurring among patients with mean HbA<sub>1c</sub> 7.0-7.4% (8.7, 7.8-9.6) and significantly higher rates among those with HbA<sub>1c</sub> <6% (16.2, 14.5-18.0), 6-6.4% (12.4, 11.3-13.7), and ≥9% (14.4, 12.3-16.9). Relative to patients with HbA<sub>1c</sub> 7-7.4%, the fully adjusted Cox models showed significantly greater risk of CVDh among patients with mean HbA<sub>1c</sub> <6%, 6.0-6.4%, 6.5-6.9%, 8.5-8.9%, and ≥9% (table). Mortality risk was also significantly greater for patients with mean HbA<sub>1c</sub> <6%, 6.0-6.4%, 6.5-6.9%, and ≥9% relative to 7.0-7.4%.

**Conclusion:** The association of mean HbA<sub>1c</sub> with CVDh and all-cause mortality is U-shaped even after accounting for numerous other risk factors, suggesting that guidelines for glycemic control might need to include minimum HbA<sub>1c</sub> targets.

Adjusted Hazard Ratios for CVD Hospitalizations and All-Cause Mortality

Mean A1C	CVD Hospitalization			All-Cause Mortality		
	Hazard Ratio	95% CI	P Value	Hazard Ratio	95% CI	P Value

### Glycaemic treatment responders in real life have lower risk of cardiovascular disease and total mortality - an observational study from the Swedish NDR

K. Eeg-Olofsson<sup>1</sup>, B. Eliasson<sup>1</sup>, B. Zethelius<sup>2</sup>, A.-M. Svensson<sup>3</sup>, S. Gudbjörnsdottir<sup>1</sup>, J. Cederholm<sup>2</sup>;<sup>1</sup>Institute of Medicine, Gothenburg, <sup>2</sup>Department of Public Health and Caring Sciences, Uppsala, <sup>3</sup>Centre of Registers in Region Västra Götaland, Gothenburg, Sweden.

**Background and aims:** The relationship between glycaemic control and cardiovascular risk in type 2 diabetes (T2D) remains unclear. The aim of this observational study was to assess the association between improved glycaemic control during follow-up and risk for coronary heart disease (CHD), cardiovascular disease (CVD) and total mortality in patients with T2D from the Swedish National Diabetes Register.

**Materials and methods:** 18035 patients with baseline HbA<sub>1c</sub> 7-8.9%, aged 30-75 years and with no previous CVD, were identified in 2003-2006, and follow-up until December 2009 (mean 5.7 years). Two groups of patients were created based on the median for change in HbA<sub>1c</sub> during follow-up: 8923 patients (mean baseline age 62.0 years, diabetes duration 8.3 years) with HbA<sub>1c</sub> decreasing 0.1% or more from baseline to follow-up (mean baseline HbA<sub>1c</sub> 7.8±0.5% and final 7.0±0.6%), and 9112 patients (mean baseline age 61.3 years, duration 9.2 years) with stable or increasing HbA<sub>1c</sub>, more than or equal to 0% from baseline to follow-up (mean baseline HbA<sub>1c</sub> 7.7±0.5% and final 8.3±0.9%).

**Results:** Absolute risk of first-incident fatal/nonfatal CVD was 15.1 events per 1000 person-years in patients with decreasing HbA<sub>1c</sub> and 26.1 in patients with stable/increasing HbA<sub>1c</sub>. Adjusted hazard ratios at Cox regression analysis for first-incident fatal/nonfatal CHD, fatal/nonfatal CVD and total mortality, with decreasing HbA<sub>1c</sub> compared to stable/increasing HbA<sub>1c</sub>, were 0.61 (95% CI 0.53-0.69), 0.63 (0.56-0.70), and 0.56 (0.50-0.64), respectively, all p<0.001. Adjustment was made for a propensity score with stratification by octiles, including covariates age, sex, diabetes duration, baseline HbA<sub>1c</sub> and traditional CVD risk factors and treatments, as well as changes in these risk factors and treatments during the study period. Differences in included covariates between the two groups were balanced when adjusted with the propensity score.

**Conclusion:** In T2D patients in real life an HbA<sub>1c</sub> reduction of mean 0.8% from mean 7.8% to 7.0% (to the treatment target) was associated with substantially lower risk of CHD, CVD and total mortality, compared to patients with stable/increasing HbA<sub>1c</sub> of 7.7-8.3%.

### Effect of screening for type 2 diabetes on population mortality over ten years: the ADDITION-Cambridge cluster-randomised controlled trial

R.K. Simmons<sup>1</sup>, J.B. Echouffo-Tcheugui<sup>1</sup>, S.J. Sharp<sup>1</sup>, L.A. Sargeant<sup>1</sup>, K.M. Williams<sup>2</sup>, A.T. Prevost<sup>2</sup>, A.-L. Kinmonth<sup>2</sup>, N.J. Wareham<sup>1</sup>, S.J. Griffin<sup>1</sup>;<sup>1</sup>MRC Epidemiology Unit, <sup>2</sup>Department of Public Health and Primary Care, General Practice and Primary Care Research Unit, Cambridge, UK.

**Background and aims:** Uncertainty persists concerning the benefits of screening for type 2 diabetes. We assessed the impact of a population-based stepwise screening programme on mortality in a cluster-randomised trial.

**Materials and methods:** 33 practices in Eastern England were allocated in an unbalanced design to i) screening followed by intensive multifactorial treatment for detected diabetes (IT, n=15), ii) screening plus routine care according to national guidelines (RC, n=13) and iii) a no-screening control group (n=5). The study population comprised 20,184 individuals aged 40-69 years, at high risk of prevalent undiagnosed diabetes, based on a previously validated risk score. In screening practices, individuals were invited to a stepwise programme including random capillary blood glucose and HbA<sub>1c</sub> tests, a fasting capillary test, and a confirmatory oral glucose tolerance test. The primary analysis was by intention-to-screen and compared all-cause mortality rates between screening (IT and RC combined) and control groups after a median 9.6 years of follow-up, allowing for the cluster design.

**Results:** Of 16,047 high-risk individuals in screening practices, 15,089 (94%) were invited for screening during 2001-06, 11,737 (73.1%) attended and 466 (2.9%) were diagnosed with diabetes. 4,137 control individuals were followed-up. During 184,057 person-years of follow-up, there were 1,532 deaths in the screening practices and 377 in control practices (mortality hazard ratio [HR]: 1.06, 95% CI 0.90,1.25) (Figure One). There was no significant

reduction in cardiovascular (HR: 1.02, 95% CI 0.75,1.38), cancer (HR: 1.08, 95% CI 0.90,1.30) or diabetes-related mortality (HR: 1.26, 95% CI: 0.75,2.10) associated with invitation to screening. Compared with the control group, screening attenders had a lower mortality (HR: 0.69, 95%CI 0.59-0.80) and non-attenders had a higher mortality (HR: 1.36, 95% CI 1.07 - 1.72). **Conclusion:** In this large UK sample, population-based screening for type 2 diabetes was not associated with a reduction in all-cause, cardiovascular or diabetes-related mortality over a median 9.6 years. Attendance was associated with a significantly lower mortality risk. **Figure 1** Cumulative incidence of death in the screening and no screening control groups in the ADDITION-Cambridge trial

Clinical Trial Registration Number: ISRCTN86769081

### Glycaemic control and mortality at the intensive care unit: differences between patients with and without diabetes mellitus

M.K. Sechterberger<sup>1</sup>, R.J. Bosman<sup>2</sup>, H.M. Oudemans-van Straaten<sup>2</sup>, J.B.L. Hoekstra<sup>1</sup>, J.H. De Vries<sup>1</sup>

<sup>1</sup>Internal Medicine, Academic Medical Centre, <sup>2</sup>Intensive Care Medicine, Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands.

**Background and aims:** Hyperglycaemia, hypoglycaemia and increased glucose variability in critically ill patients are independently associated with intensive care unit (ICU) mortality. These associations might be different in patients with and without pre-existing diabetes mellitus (DM). We investigated the extent to which three measures of glycaemic control over the duration of ICU admission, namely mean glucose concentration, glucose variability and the occurrence of hypoglycaemia, were associated with ICU mortality in patients with and without pre-existing DM.

**Materials and methods:** We performed a single-centre retrospective database cohort study including patients admitted from January 2004 to July 2011 in a 24-bed medical/surgical ICU in a teaching hospital in the Netherlands. Hyperglycaemia was treated using a computerized glucose regulation protocol. Diabetic status was defined by the use of anti-diabetic drugs at ICU admission. The non-DM and DM cohorts were subdivided into quintiles of increasing mean glucose and quartiles of glucose variability (measured as mean absolute glucose (MAG) change). Multivariable regression models were used to examine the independent association between ICU mortality and mean glucose, MAG change, and the occurrence of severe ( $\leq 2.2$  mmol/l) and mild ( $\leq 4.7$  mmol/l) hypoglycaemia.

**Results:** In total, 10,328 patients (8690 non-DM patients and 1638 DM patients) were eligible for analysis. Regarding mean glucose concentration, a U-shaped curved relation was observed in the non-DM cohort with significant increased ICU mortality in the lowest and highest mean glucose quintiles (OR 1.4 and 1.8 respectively,  $p < 0.001$ ). No clear pattern was found in the DM-cohort with no significant association between mean glucose and ICU mortality in logistic regression analysis ( $p$  for trend = 0.718). Glucose variability was only related with ICU mortality in the non DM-cohort, with significantly higher ICU mortality in the upper MAG change quartile (OR 1.62,  $P < 0.001$ ). Furthermore, in both cohorts the occurrence of severe hypoglycaemia ( $\leq 2.2$  mmol) was significantly associated with ICU mortality (adjusted

OR non-DM cohort: 2.5,  $p < 0.001$ ; DM cohort: 4.3,  $p = 0.001$ ). Mild hypoglycaemia ( $\leq 4.7$  mmol/L) was only significantly associated with ICU mortality in the non-DM cohort (adjusted OR 1.6,  $p < 0.001$ ).

**Conclusion:** Mild hypoglycaemia, high glucose variability and hyperglycaemia are related to ICU mortality in the non-DM, but not in the DM cohort, whereas severe hypoglycaemia was associated with ICU mortality in both. In the non-DM population, moderate targets seem therefore safest.

## 185

### Predictors of coronary artery disease in type 1 diabetes differ by level of glycaemic control

T.J. Orchard, R.G. Miller;

Epidemiology, University of Pittsburgh, Pittsburgh, USA.

**Background and aims:** Glycaemia has not been a consistent predictor of coronary artery disease (CAD) in T1D, however analyses are often based on a single HbA1c value. Thus, we examined further risk factors for CAD incidence in groups characterized by long-term HbA1c to explore whether these factors may partially explain why individuals with consistently good glycaemic control remain at elevated risk for CAD.

**Materials and methods:** Data are from 311 individuals in the Epidemiology of Diabetes Complications (EDC) study of childhood-onset ( $<17$  years old) T1D without baseline CAD and attendance at least 3 of the 7 possible examinations over the 18 year follow-up period (baseline mean age 27.0, T1D duration 18.4 yrs, 45% female). Incident CAD ( $n=82$ , 26%) was defined as a confirmed event (CAD death, myocardial infarction, revascularization/blockage  $\geq 50\%$ , ischemic ECG, or EDC physician-diagnosed angina) occurring prior to the 18-yr exam. The EDC cohort was divided into tertiles based on the mean of each participant's HbA1c percentile for each exam over the follow-up period. Individuals studied comprised those with a mean HbA1c percentile in the lowest 1/3 (Low A1c, 18-yr mean HbA1c=7.7% ) versus those in the highest 1/3 (High A1c, 18-yr mean HbA1c=10.0% ). Separate proportional hazards models for baseline risk factors were fit by HbA1c category.

**Results:** The High A1c group had significantly higher CAD incidence (31.9% versus 20.8% in Low A1c,  $p=0.03$ ). Univariately, standard lipid and blood pressure measures and estimated glomerular filtration rate (eGFR) predicted CAD in both A1c groups, however haemoglobin, haematocrit, red blood cell count, and white blood cell count predicted incident CAD in the Low A1c group only ( $p<0.05$  for all). After covariate adjustment, beyond diabetes duration, only hypertension remained a significant predictor of CAD in the High A1c group (HR=3.6,  $p=0.001$ ), while in the Low A1c group hypertension (HR=2.4,  $p=0.04$ ) and lower eGFR (per SD decrement HR=1.6,  $p=0.02$ ) were significant predictors of CAD. Indeed, there was a significant interaction between A1c and eGFR ( $p=0.006$ ), such that within the Low A1c group, individuals with low eGFR ( $<60$  ml/min/1.73m<sup>2</sup>) developed CAD more frequently than those without low eGFR (53% versus 17%,  $p=0.003$ ), while in the High A1c group, this difference was not as marked and 31% of individuals without low eGFR went on to develop CAD (versus 50% with low eGFR,  $p=0.29$ ).

**Conclusion:** These data suggest risk factor effects differ by glycaemic status and emphasize that, in the setting of lower HbA1c in T1D, renal function may be a particularly important factor in the development of CAD.

## 186

### Diabetes management among adults under excellent control in the type 1 diabetes exchange clinic registry: How do they do it?

J.B. McGill<sup>1</sup>, V. Chen<sup>2</sup>, R.W. Beck<sup>3</sup>

<sup>1</sup>School of Medicine, Washington University in St. Louis, <sup>2</sup>Biostatistics, Jaeb Center for Health Research, Tampa, <sup>3</sup>Jaeb Center for Health Research, Tampa, USA.

**Background and aims:** Optimizing glycemic control in type 1 diabetes is important to minimize the risk of complications. Why are some patients able to achieve excellent control and others are not? We used the large T1D Exchange database to identify differences in patient characteristics and in diabetes management techniques by comparing patients  $\geq 18$  years old with excellent control versus those with poorer control.

**Materials and methods:** The T1D Exchange includes a network of 67 clinics with a registry of approximately 25,000 individuals with type 1 diabetes. Among participants  $\geq 18$  years old, those with HbA1c levels  $<6.5\%$  ( $N=889$ )

were compared with those with HbA1c levels  $\geq 8.5\%$  ( $N=2314$ ) using data obtained through a standardized data collection. Statistical comparisons were made between the two groups.

**Results:** Compared with the participants with HbA1c levels  $\geq 8.5\%$ , participants with HbA1c levels  $< 6.5\%$  were more often non-Hispanic whites, married, and working full time; had higher education and income levels; and more often had private insurance ( $P<0.001$  for each factor). With respect to diabetes management, participants with HbA1c levels  $< 6.5\%$  more often used an insulin pump, gave meal bolus before rather than after starting a meal, varied insulin: carb ratio for breakfast, lunch, and dinner; checked the blood glucose level  $\geq 6$  per day; and checked the blood glucose before giving a bolus, as seen in the table below ( $P<0.001$  for each factor). Daily total insulin/kg was lower in the group with better control ( $0.6\pm 0.3$  versus  $0.8\pm 0.4$  units/kg/day,  $P<0.001$ ).

	HbA1c <6.5%	HbA1c $\geq 8.5\%$
Non-Hispanic White	94%	81%
Education: Bachelor's or higher	63%	24%
Annual income $\geq \$75,000$	63%	36%
Married	58%	29%
Working full time	50%	33%
Private insurance	86%	70%
Using insulin pump	60%	48%
Gives insulin bolus prior to starting meal	67%	47%
Varied insulin:carbohydrate ratio at the 3 meals	37%	21%
Blood glucose measurements $\geq 6$ times/day	53%	18%
Always checks blood glucose before bolusing	52%	25%

**Conclusion:** Individuals with excellent glycemic control tend to be of higher socio-economic status than those with poorer control. They also tend to manage their diabetes differently with respect to insulin delivery modality, frequency of blood glucose monitoring, timing of meal boluses, use of insulin: carbohydrate ratios, and require lower insulin doses on average.

## OP 32 Insights in diabetic retinopathy

187

### Yield of referable retinopathy in the Scottish diabetic retinopathy screening programme

H.C. Looker<sup>1</sup>, D. Cromie<sup>2</sup>, Scottish Diabetic Retinopathy Screening Collaborative, Scottish Diabetes Research Network Epidemiology Group; <sup>1</sup>Medical Research Institute, University of Dundee, <sup>2</sup>Department of Public Health, NHS Lanarkshire, Glasgow, UK.

**Background and aims:** Screening for diabetic retinopathy is a vital part of diabetes care. Scotland launched a national diabetic retinopathy screening programme in 2006 with annual photography for all patients aged  $\geq 12$  years. We examined the yield of disease requiring referral to specialist eye care for the first 5 years of the programme.

**Materials and methods:** Retinal screening results were obtained from the national clinical diabetes database (SCI-DC) which contains data on  $\sim 99\%$  of people with diagnosed diabetes in Scotland. Those with severe retinal haemorrhages, venous beading or intra-retinal microvascular anomalies (referable retinopathy), new vessels (proliferative) and those with exudates or blot haemorrhages adjacent to the fovea (referable maculopathy) on centrally graded photographs are referred to specialist eye care.

**Results:** 21,295 people with type 1 diabetes and 169,072 people with type 2 diabetes underwent at least one successful retinal screening between 2006 and 2010 (median screens per person = 2). The first 2 years of screening had the highest yield of referable eye disease (6.9% and 5.4%) before stabilizing at 3.8% (standard error 0.05%). The prevalence of referable eye disease for type 1 diabetes was higher than for type 2 diabetes (see figure) in each year (Odds ratio for type 1 versus type 2 diabetes 3.5 (95% Confidence Interval 3.2–3.8) after adjustment for age and sex. The risk associated with type 1 diabetes was not uniform across all diabetes durations. For diabetes durations  $< 10$  years the OR for Type 1 diabetes vs. type 2 diabetes was 0.7 (0.5 – 0.9) whereas for durations  $\geq 10$  years the OR was 1.3 (1.2 – 1.4) (all OR adjusted for age and sex).

**Conclusion:** The annual national retinopathy screening programme in Scotland has yielded a substantial number of cases of referable disease leading to preventive action in the first five years of operation. This is especially the case for T1D for people with a diabetes duration  $\geq 10$  years. Further review of the yield will enable on-going cost-benefit analysis of the programme.

### Prevalence of referable diabetic eye disease at retinal screening

### CACNB2 is a novel susceptibility gene for diabetic retinopathy

N. Vuori<sup>1</sup>, K. Hietala<sup>2,1</sup>, N. Sandholm<sup>1</sup>, C. Forsblom<sup>1,3</sup>, P. Summanen<sup>2</sup>, M. Lehto<sup>1</sup>, P.-H. Groop<sup>1,3</sup>

<sup>1</sup>Folkhälsan Research Center, <sup>2</sup>Department of Ophthalmology, Helsinki University Central Hospital, <sup>3</sup>Division of Nephrology, Department of Medicine, Helsinki University Central Hospital, Finland.

**Background and aims:** We have recently performed a linkage analysis on diabetic retinopathy, where we identified a region on chromosome 10 harbour-

ing an interesting candidate gene, *CACNB2*. The gene encodes the voltage-dependent L-type calcium channel subunit beta-2, which previously has been shown to associate with night-blindness in mice. A microsatellite (D10S548) was found in *CACNB2* with a LOD score of 2.73. The aim of this study was to confirm the linkage finding in a large scale case-control study of patients with type 1 diabetes.

**Materials and methods:** The patient population consisted of 1350 cases with severe diabetic retinopathy (SDR) and 1543 controls without SDR from the Finnish Diabetic Nephropathy (FinnDiane) Study. SDR was defined based on the presence of laser treatment and the controls were required to have at least 15 years duration of diabetes without SDR. The association study was performed as a lookup of our GWAS data originally collected for diabetic nephropathy. We selected genotyped SNPs within the gene and 10 kb upstreams and downstreams of the gene ( $n = 163$ ). Logistic regression with sex, age, and duration of diabetes as covariates was used for the analyses.

**Results:** 62 SNPs showed a  $p$ -value of  $< 0.05$  and 15 SNPs had a  $p$ -value of  $< 0.01$ . The SNP with the lowest  $p$ -value for severe retinopathy was rs4548524 with an OR of 0.819 (95% CI 0.671–0.990) and a  $p$ -value of 0.001. This SNP would not survive a robust correction for multiple testing, however, this particular SNP was closely located ( $< 5$  kb) to the linkage marker D10S548 with the highest LOD-score in the linkage analysis, thus supporting the importance of this locus. Nimblegen sequencing of an area of 219,738 bp on the gene that encompasses the linkage and association findings, is ongoing in an effort to identify potential gene variants associated with SDR. Preliminary data show two novel missense mutations (Arg-Cys, Ser-Leu) at the c-terminal half of the protein.

**Conclusion:** Our finding supports the hypothesis that variants in the gene *CACNB2* may confer genetic susceptibility to diabetic retinopathy in patients with type 1 diabetes.

## 189

### Activated microglial cells promote vasoregression

S. Busch<sup>1</sup>, L. Wu<sup>1</sup>, N. Gretz<sup>2</sup>, S. Hoffmann<sup>2</sup>, H.-P. Hammes<sup>1</sup>

<sup>1</sup>5th Medical Department, <sup>2</sup>Medical Research Center, Medical Faculty Mannheim, University of Heidelberg, Mannheim, Germany.

**Background and aims:** Neurodegeneration, activation of glial cells and vasoregression are hallmarks of early diabetic retinopathy. A similar pathomechanism is found in the euglycemic, neurodegenerative PKD rat. Microglial activation has been shown by upregulation of CD74, the invariant chain of MHCII. The increase was predominantly localized in the deep capillary layer of the PKD model, the layer which is commonly concerned by retinopathy at first. Consequently, microglial cells could mediate vasoregression. To determine the extent of vasoregression caused by microglial activation, number of acellular capillaries in the PKD model was evaluated after depletion of microglial cells.

**Materials and methods:** Transgenic rats TGR(CMV-PKD2<sub>(1/703)</sub>,HA) of one and two months were treated with intravitreal injection of 3  $\mu$ l Clodronate-coated liposomes. Animals were sacrificed after one week and eyes were enucleated. Untreated animals were used as controls. After fixation with formalin, retinae were taken out and incubated with primary antibodies against CD11b (AbD Serotec MCA275G) and CD74 (Santa Cruz sc20082). Swine-anti-rabbit Tritic (Dako R0156) and donkey-anti-goat AlexaFluor488 (Invitrogen A11055) were used as secondary antibodies. Confocal laser scanning microscopy was used to evaluate the number of positive staining for CD11b and CD74 in different retinal layers. Quantification of acellular capillaries occurred in retinal digest preparations. Formalin-fixated eyes were treated for 1.5h with pepsin, followed by 15–30min trypsin digestion. The remaining vessel network was stained with PAS and hematoxylin. Acellular capillaries were counted by using an integration ocular.

**Results:** Number of CD11b positive cells were increased by 27% ( $p < 0.05$ ) in the superficial and 400% ( $p < 0.01$ ) in the deep vessel network of PKD rats compared with control animals. Expression of CD74 in the superficial vessel network was threefold higher ( $p < 0.05$ ). In comparison with control rats, which don't express CD74 in the deep vessel network, 83% of all CD11b positive cells in the deep vessel network of PKD rats were also positive for CD74. Treatment with Clodronate reduced number of positive CD11b cells in the superficial layer by 27% ( $p < 0.05$ ). Superficial CD74 expression increased eightfold ( $p < 0.01$ ), whereas CD74 expression in the deep vessel network was reduced by 50% ( $p < 0.05$ ). Number of acellular capillaries in the superficial vessel network decreased after treatment of 1 month old animals by 14% (n.s.). The reduction in the deep vessel network was 30% ( $p < 0.01$ ). In

2 months old animals, number of superficial acellular capillaries increased by 5% (n.s.), whereas number of acellular capillaries in the deep vessel layer declined by 28% ( $p < 0.05$ ).

**Conclusion:** Number of acellular capillaries, caused by transgenic neurodegeneration, can be reduced by depletion of microglial cells. Therefore, activation of the innate immunity system, especially microglial cells, promotes vasoregression. Consequently, microglial cells and prevention of their activation could be a target to treat vasoregression.

## 190

### High glucose induces mitochondrial dysfunction in retinal Muller cells: implications for diabetic retinopathy

T. Tien, T. Muto, S. Roy;  
Boston University, USA.

**Background and aims:** Muller cell loss has been associated with the development of early stage diabetic retinopathy, a leading cause of blindness in the working age population. In the retina, Muller cells are intimately associated with the vasculature and the neurons and play a key role in the maintenance of overall retinal homeostasis and function. Hyperglycemia-induced oxidative stress has been implicated in promoting Muller cell apoptosis in diabetic retinopathy, and recent studies indicate that changes in mitochondrial morphology increase oxidative stress and trigger apoptosis. However, it is unclear whether high glucose induces mitochondrial dysfunction and promotes apoptosis in retinal Muller cells. In this study, we determined whether high glucose promotes apoptosis in rat retinal Muller cells (rMC-1) by inducing biochemical and morphological changes in mitochondria.

**Materials and methods:** To determine if high glucose (HG) induces mitochondrial morphology changes, rMC-1 were grown in normal (N, 5mM glucose) or HG (30mM) medium for 6 days. Cells were stained with MitoTracker Red, and digital images were captured through live cell imaging under confocal microscopy. Images were analyzed for mitochondrial morphology changes based on Form Factor (FF) and Aspect Ratio (AR). Temporal effects of HG on mitochondrial morphology were examined at 15, 30, 45, 60, 90, and 120 minutes by analyzing FF and AR changes. Altered mitochondrial metabolic function under HG was assessed by measuring oxygen consumption rate (OCR) using XF24 bioenergetic assay. In parallel, TUNEL assay was performed to determine cells undergoing apoptosis, and cytochrome c levels were assessed using Western blot analysis.

**Results:** Cells grown in HG medium exhibited significantly increased mitochondrial fragmentation compared to those grown in N medium (FF =  $1.7 \pm 0.1$  vs  $2.3 \pm 0.1$ ; AR =  $2.1 \pm 0.1$  vs  $2.5 \pm 0.2$ ;  $p = 0.002$  and  $0.03$ , respectively). Time course studies indicate that HG-induced mitochondrial fragmentation follows a bimodal pattern in which initial fragmentation is followed by a recovery period; however, after 48h of HG exposure, permanent mitochondrial fragmentation was observed for the rest of the study. OCR was significantly reduced in rMC-1 grown in HG medium compared to those grown in N medium (76%  $\pm$  13% of control). The number of TUNEL positive cells was significantly increased in cells grown in HG medium compared to those grown in N medium (183%  $\pm$  35% of control,  $p = 0.002$ ) with concomitant increase in cytochrome c levels (247%  $\pm$  94% of control,  $p = 0.03$ ), as determined from WB analysis.

**Conclusion:** Findings from this study indicate that HG promotes mitochondrial dysfunction in retinal Muller cells by inducing mitochondrial morphology changes with concomitant increase in cytochrome c and apoptosis. HG-induced mitochondrial morphology changes and subsequent mitochondrial dysfunction may play a key role in retinal Muller cell loss associated with diabetic retinopathy.

## 191

### Neurophysiological alterations in a mouse model of proliferative retinopathy

P. Villacampa<sup>1</sup>, V. Haurigot<sup>1</sup>, S. Motas<sup>1</sup>, A. Ribera<sup>1</sup>, L. Ramirez<sup>2</sup>, P. de la Villa<sup>2</sup>, F. Bosch<sup>1</sup>

<sup>1</sup>Universitat Autònoma de Barcelona, Bellaterra, <sup>2</sup>Universidad de Alcalá, Alcalá de Henares, Spain.

**Background and aims:** Diabetic retinopathy is the leading cause of loss of visual acuity and blindness in adulthood and constitutes an unmet medical

need. Most diabetic rodents do not develop a complete phenotype of proliferative retinopathy, but only mild vascular alterations. In contrast, transgenic mice overexpressing Insulin-like Growth Factor (Tg-IGF-I) in the retina have retinal alterations characteristic of non-proliferative retinopathy that, with age, develop to proliferative disease, with neovascularization and retinal detachment. Then, vascular alterations evolve in a progressive manner through the animal's life, similar to those of the human disease. The aim of this work was to determine whether neuronal and glial function were also affected in these animals, as observed in human diabetic patients.

**Materials and methods:** Electroretinographic (ERG) responses were recorded in dark-adapted mice (3, 6, 7.5 and 9 months-old TgIGF-I and age-matched wild-types (Wt), with intensities that ranged from -4 to 2 log cd•s•m<sup>-2</sup>. Immunohistochemistry for neuronal and glial markers was performed in paraffin-embedded retinal sections, and neuronal populations were quantified by morphometric analysis. The expression of genes key to glial metabolism were studied by qRT-PCR. Glutamate and glutathione quantity and glutamine synthetase activity were assessed spectrophotometrically. Other markers of oxidative stress were analyzed by using Western blot and qPCR.

**Results:** No alterations were observed in the ERG of 3 months-old TgIGF-I mice, in neither scotopic nor photopic conditions. At 6 months of age, abnormal responses were detected in some but not all TgIGF-I, but it was not until 7.5 months of age that differences became statistically significant. At this point, all transgenic mice showed more than 50% reduction in amplitudes of both a and b waves in all range of intensities. Furthermore, all mice aged 9 months were completely blind. By histological analysis, decreased populations of bipolar, amacrine and ganglion neurons were found at 7.5 months of age. Moreover, rod photoreceptors showed decreased outer segment length. Gliosis and microgliosis were detected in transgenic mice at early ages. Transgenic mice showed alterations in the glutamate metabolism, signs of oxidative stress and impaired potassium buffering. Increased production of pro-inflammatory cytokines such as Tumour Necrosis Factor alpha (TNF-α) and Monocyte Chemoattractant Protein-1 (MCP-1) were also observed at this age.

**Conclusion:** TgIGF-I mice presented a progressive decline in retinal neuronal function and reduced cellular populations. Loss of vision correlated in time with overt retinal neovascularization, vascular leakage and was preceded by glial and microglial activation. Glial dysfunction may underlie neuronal damage in transgenic retinas, which could be exacerbated by increased production of pro-inflammatory cytokines. Most of these glial alterations have also been reported in human diabetic retinas, making TgIGF-I a suitable model for the study of new therapeutic approaches for diabetic retinopathy. Supported by: Plan Nacional I+D+I (SAF2008-00962, SAF2011-24698), Spain

(RBZ+laser) RBZ injections in the 2<sup>nd</sup> year, with a mean BCVA change of +7.9 (RBZ) and +6.7 (RBZ+laser) letters at M24. The mean CRT change at M12 (RBZ: -127.8μm and RBZ+laser: -139.7μm) was maintained at M24 (RBZ: -140.6μm and RBZ+laser: -133.0μm). In patients treated with only laser in the core phase, mean BCVA gain of +2.3 letters at M12 further improved to +5.4 letters at M24 with an average of 4.1 RBZ injections in the 2<sup>nd</sup> year; mean CRT decreased further from -63.3μm (M12) to -126.6μm (M24). Mean change in VF (Day1-M24) for RBZ/RBZ+laser/laser was +10.8/+10.5/+4.6 points (near activity), +5.1/+7.0/+2.8 points (distance activity) and +5.6/+5.8/+4.3 points (composite score). 3-year (Day1-M36) results of safety and efficacy of RBZ will also be presented.

**Conclusion:** The AEs reported over 2 years were consistent with the published safety profile of RBZ in DME. In the 2<sup>nd</sup> year, an average of 3.8 RBZ injections over the three core treatment groups was sufficient to maintain (RBZ/RBZ+laser) or improve (laser) BCVA, and CRT outcomes in the RESTORE extension study. RBZ treatment was associated with VF improvements in all treatment groups over 2 years. The outcome of the RESTORE extension study provides additional evidence for the long-term safety and efficacy of RBZ in DME.

*Clinical Trial Registration Number: NCT00906464*

## 192

### Long-term safety and efficacy of ranibizumab 0.5 mg in patients with diabetic macular oedema of the RESTORE extension study

G.E. Lang, on behalf of the RESTORE Extension Group;  
Ophthalmology, University Eye Hospital Ulm, Germany.

**Background and aims:** Diabetic macular edema (DME) is the leading cause of blindness in diabetic patients (pts). The RESTORE core study was the first study to demonstrate that ranibizumab monotherapy (RBZ) or combined with laser (RBZ+laser) achieved superior visual acuity gain vs laser monotherapy in patients with visual impairment due to DME. The RESTORE extension study provides long-term evidence for safety and efficacy of RBZ in DME.

**Materials and methods:** 24-month (M), open-label, multicenter, Phase-IIIb, extension study. Among the 303 pts who completed RESTORE core study (Day1-M12) 240 pts (79%) entered the extension study (M12-M36); all pts (RBZ/RBZ+laser/laser) were eligible to receive RBZ PRN according to pre-specified stability-based best-corrected visual acuity (BCVA) and DME progression re-treatment criteria, and laser PRN according to Early Treatment Diabetic Retinopathy Study guidelines. Interim analysis at M24 (12M core phase + 12M extension phase[Day1-M24]) and full analysis at M36 (12M core phase + 24M extension phase[Day1-M36]) of the incidence of adverse events (AEs), treatment exposure, changes in BCVA, patient-reported visual functioning (VF, assessed by Visual Functioning Questionnaire [VFQ-25]) and central retinal subfield thickness (CRT) are presented. Last observation carried forward approach was used for BCVA, VF and CRT analysis.

**Results:** 220 pts (92%) completed the M24 visit. Neither new AEs nor new safety risks were revealed in the 2-year analysis. There were no cases of endophthalmitis. There were 4 deaths between M12-M24 (none related to study drug/procedure). The mean BCVA gain of +7.9 (RBZ) and +7.1 (RBZ+laser) letters at M12 was maintained with an average of 3.9 (RBZ) and 3.5

## OP 33 Devices, algorithms and their application

193

### Short-term glucose prediction algorithm reduces hypoglycaemia among virtual patients

A. Roy, B. Keenan, G. Spital, B. Clark, B. Grosman, J.J. Mastrototaro, F.R. Kaufman;

Medtronic Diabetes, Northridge, USA.

**Background and aims:** The Paradigm® Veo™ pump with a threshold low glucose suspend (LGS) interrupts basal infusion for a maximum of 2 hours once sensor glucose (CGM) values drop below a user-defined threshold. Clinical studies have shown that LGS minimizes time spent in hypoglycemia. However, a preferable approach might be to suspend insulin delivery 20–30 min in advance of a hypoglycemic event. This could be achieved by using a predictive low glucose management (PLGM) algorithm to predict future hypoglycemia, suspend basal insulin 30 minutes prior to the event, and then resume delivery based on predicted glucose levels. An *in silico* study with hypoglycemic challenges was done to compare the efficacy of LGS and PLGM in reducing the frequency and severity of hypoglycemic events.

**Methods:** Hypoglycemic challenges were simulated using the FDA-accepted University of Virginia glucose simulator with 20 virtual patients. The study consisted of three arms: Arm A - control (no pump suspension); Arm B - hypoglycemia mitigation via PLGM; Arm C - hypoglycemia mitigation via LGS. In order to induce hypoglycemia, the virtual patients received a manual bolus after the commencement of study. The bolus amount was patient specific (based on insulin sensitivity) and was chosen such that the blood glucose nadir was between 50 and 70 mg/dL. For both algorithms, the pump suspension threshold was set at 70 mg/dL. For PLGM, the 30 min glucose prediction was performed by a time-series forecasting approach.

**Results:** Figure below illustrates the time-series plot of reference glucose values (median, 2.5<sup>th</sup>–97.5<sup>th</sup> percentile range) of all arms. The data revealed that PLGM reduced hypoglycemia (<70 mg/dL) by 26.7% compared to no insulin suspension, as opposed to a 5.3% reduction in hypoglycemia with use of LGS. The mean duration of hypoglycemia (time spent <70 mg/dL) with PLGM was significantly less than with LGS (58 min vs 101 min, respectively,  $p < 0.001$ ). With PLGM, the mean ( $\pm$  SD) time gain in forecasting hypoglycemic events was 30.6 ( $\pm$  12.8) min.

**Conclusion:** *In silico* modeling has demonstrated that predictive algorithms may further reduce the severity of hypoglycemia beyond that already established for algorithms that use a threshold-based suspension.

### Time in hypoglycaemia in patients with type 1 diabetes is dramatically reduced when insulin infusion is driven by two closed-loop algorithms in a randomised clinical trial

Luijck<sup>2</sup>, L. Leelarathna<sup>3</sup>, J.K. Mader<sup>4</sup>, C. Benesch<sup>5</sup>, D. Bruttomesso<sup>6</sup>, F. Di Palma<sup>7</sup>, M. Nodale<sup>3</sup>;

<sup>1</sup>Department of Endocrinology, Diabetes, Nutrition, Montpellier University Hospital, France, <sup>2</sup>Department of Internal Medicine, Academic Medical Center at the University of Amsterdam, Netherlands, <sup>3</sup>Institute of Metabolic Science, University of Cambridge, UK, <sup>4</sup>Department of Internal Medicine, Medical University of Graz, Austria, <sup>5</sup>Profil Institute, Neuss, Germany, <sup>6</sup>University of Padova, Italy, <sup>7</sup>University of Pavia, Italy.

**Background and aims:** Closed loop algorithms built for model predictive control (MPC) aim to keep blood glucose close to normal in patients with Type 1 diabetes by the tuning of insulin delivery based on continuous glucose monitoring (CGM) and prediction of glucose levels.

**Materials and methods:** Blood glucose was controlled for 23 h in 47 patients in six centers by one of two MPC algorithms developed either at the University of Pavia with a Safety Supervision Module from UVA & UCSB (iAP) or at Cambridge University (CAM), or by the patients themselves in Open Loop (OL) mode, in a randomized three-way cross-over design during three clinical research center admissions including three meals and an exercise bout. CGM data were provided by the Dexcom Seven Plus (Dexcom Inc, San Diego, CA, USA) and insulin was administered by Omnipod Insulin Pump (Insulet Corp, Bedford, MA, USA), either automatically with the Artificial Pancreas System (UCSB/Sansum, CA, USA) (three centers) or manually (three centers). For glucose reference measurements the YSI glucose analyzer was used. Intention-to-treat (ITT) and per-protocol (PP) analyses were done using a general linear model for repeated measures. For the PP analysis, 0.4% (OL), 13% (iAP) and 17% (CAM) of time was discarded because of CGM or insulin pump malfunction or operator mistakes.

**Results:** Percentage of time spent in euglycaemia (3.9–8, postmeal 10 mmol/L) was similar in closed and open loop modes, both in ITT and PP analyses: 62.6 and 62.8 for OL, 59.2 and 59.3 for iAP, 58.3 and 59.6 for CAM. While mean glucose level (mmol/L) was significantly lower in open loop mode, both in ITT and PP analyses: 7.19 and 7.18 for OL, 8.15 and 8.27 for iAP, 8.26 and 8.15 for CAM (overall  $P=0.001$ ), % time spent in hypoglycaemia (<3.9 mmol/L) was almost threefold reduced during closed loop, both in ITT and PP analyses: 6.4 and 6.3 for OL, 2.1 and 0.9 for iAP, 2.0 and 0.0 for CAM (overall  $P=0.001$ ) with less % time  $\leq 2.8$  mmol/L in ITT and PP analyses (overall  $P=0.038$  and 0.017). There were no significant differences in any of these outcomes between the two closed loop algorithms. The safety of closed-loop mode was further supported by the absence of harmful glucose deviations in case of pump or CGM failure. The feasibility of automated management of the closed-loop systems was documented in the 3 investigation centers that tested it.

**Conclusion:** From the largest and first head-to-head closed loop study performed so far, we conclude that both CAM and iAP MPC algorithms allow safer control of blood glucose than patient self management, even during meal and exercise challenges, with less hypoglycaemia at the expense of a higher mean glucose. In future trials, tuning of the algorithms will aim at increased % time in target and lower mean glucose level while keeping the reduction of hypoglycaemia.

### Efficacy and safety of reduced prandial boluses during closed-loop insulin delivery in adolescents with type 1 diabetes

D. Elleri<sup>1</sup>, J.M. Allen<sup>1</sup>, M. Biagioni<sup>1</sup>, K. Kumareswaran<sup>1</sup>, L. Leelarathna<sup>1</sup>, K. Caldwell<sup>1</sup>, M. Nodale<sup>1</sup>, M.E. Wilinska<sup>1</sup>, A. Haidar<sup>1</sup>, P. Calhoun<sup>2</sup>, C. Kollman<sup>3</sup>, M.A. Umpleby<sup>3</sup>, C.L. Acerini<sup>1</sup>, D.B. Dunger<sup>1</sup>, R. Hovorka<sup>1</sup>;

<sup>1</sup>University of Cambridge, UK, <sup>2</sup>Jaeb Center for Health Research, Tampa, USA, <sup>3</sup>Postgraduate Medical School, University of Surrey, Guildford, UK.

**Background and aims:** Closed-loop (CL) insulin delivery may be particularly efficacious when coupled with manual prandial insulin boluses. It is currently unknown if reducing prandial insulin boluses provides similar level of control whilst limiting post-prandial hyperinsulinemia and reducing risk of post-meal hypoglycaemia.

**Materials and methods:** Eight adolescents with type 1 diabetes [M 3; age  $15.9 \pm 1.5$  yrs; A1C  $8.9 \pm 1.6\%$ ; mean  $\pm$  SD; total daily dose  $0.9 (0.7, 1.1)$  IU/kg/d; median (IQR)] were studied over 36 hours (two nights and daytime) on two occasions. In random order, subjects were treated by CL with either standard insulin boluses calculated using subjects' pump bolus calculator or CL with boluses reduced by 25%. Boluses were given before main meals [(50–80 g carbohydrates (CHO)) but not with snacks (15–30 g CHO). Between-meal insulin delivery was adjusted every 15 min as per advice of a model-predictive-control algorithm informed by a real-time continuous glucose monitor. Subjects undertook moderate-intensity exercise on a stationary bicycle for 20 min in morning and afternoon. Stable-label tracer approach using intravenous [ $6,6\text{-}^2\text{H}_2$ ]glucose was employed to estimate total glucose appearance ( $R_{a\_total}$ ) and glucose disposal ( $R_d$ ).

**Results:** Overall insulin delivery was lower with reduced prandial boluses [ $61.9 (55.2, 75.0)$  vs  $72.5 (63.6, 80.3)$  IU,  $p=0.01$ ] and resulted in lower mean plasma insulin concentration [ $186 (171, 260)$  vs  $252 (198, 336)$  pmol/l,  $p=0.002$ ] but without change in plasma insulin clearance [ $16.6 (9.2, 20.9)$  vs  $15.7 (8.3, 17.5)$  ml/kg/min,  $p=0.16$ ]. Mean plasma glucose was identical ( $8.4 \pm 0.9$  mmol/l,  $p=0.97$ ). Time when plasma glucose was in target range  $3.9\text{--}10$  mmol/l was comparable [ $74 (66, 84)\%$  vs  $80 (65, 96)\%$ ,  $p=0.87$ ] and so was time above  $10$  mmol/l [ $21.8 (16.3, 33.5)\%$  vs  $18.0 (4.1, 34.2)\%$ ,  $p=0.87$ ] and time below  $3.9$  mmol/l [ $0 (0, 1.5)\%$  vs  $0 (0, 1.8)\%$ ,  $p=0.88$ ]. Hypoglycaemia occurred once 1.5 h after a meal during CL with standard bolus.  $R_{a\_total}$  was similar [ $26.3 (21.9, 28.0)$  vs  $25.4 (21.0, 29.2)$   $\mu\text{mol/kg/min}$ ,  $p=0.19$ ] as well as  $R_d$  [ $25.8 (21.0, 26.9)$  vs  $25.2 (21.2, 28.8)$   $\mu\text{mol/kg/min}$ ,  $p=0.46$ ].

**Conclusion:** Closed-loop insulin delivery coped well with 25% reduction of prandial boluses achieving glucose control and glucose turnover not different from that achieved by closed-loop with standard boluses but at reduced insulin levels. This suggests that large insulin boluses may lead to acute insulin resistance. Closed-loop with reduced boluses may be favourable in adolescents with type 1 diabetes.

### Postprandial glucose control by catheter based pumps versus patch pumps and the influence of wear time

Y.M. Luijck<sup>1</sup>, A. Avogaro<sup>2</sup>, C. Benesch<sup>3</sup>, D. Bruttomesso<sup>2</sup>, L. Heinemann<sup>3</sup>, J. Place<sup>4</sup>, E. Renard<sup>4</sup>, R. Scotton<sup>2</sup>, J.H. DeVries<sup>1</sup>, AP@home consortium;

<sup>1</sup>Internal Medicine, Academic Medical Centre, Amsterdam, Netherlands, <sup>2</sup>Department of Clinical and Experimental Medicine, University of Padova, Italy, <sup>3</sup>Profil Institut für Stoffwechselforschung GmbH, Neuss, Germany, <sup>4</sup>Internal Medicine, Montpellier University Hospital, France.

**Background and aims:** Most closed-loop systems rely on the subcutaneous administration of insulin by means of conventional insulin pumps with a catheter. Recently patch pumps have been developed to be worn directly on the body with an internal catheter of only a few centimetres between the insulin reservoir and infusion site. Both catheter length and wear time are thought to influence insulin administration. The aim of this study was to measure blood glucose profiles after bolus insulin administration by either a patch pump (PP) or a catheter based pump (CP) and the effect of catheter wear time on these profiles.

**Materials and methods:** 18 patients aged 18 or above with type 1 diabetes were recruited in 4 clinical centres of our consortium. Patients came in for two blocks of visits: one block of two visits while wearing the OmniPod In-

sulin Pump (PP visit 1 and 2) and one block of two visits while wearing the Medtronic Paradigm Pump (CP visit 1 and 2) with a 60 cm Teflon catheter. The visit blocks were in random order, using a crossover design. The first and second visits within a block were 48 hours apart to allow assessment of the effect of wear time. Patients were served an identical breakfast on all study visits and received an identical insulin bolus of at least 6 IU to cover the meal. Venous blood samples were drawn for glucose determination from one hour before breakfast until 4.5 hours afterwards. Glucose outcomes were analysed using a General Linear Model with Repeated Measures analysis (GLM-RM). If the GLM-RM detected significant overall differences, a paired t-test was performed between glucose profiles on day 1 and day 3 of wear of both pumps (intra-pump changes), and between day 1 of both pumps and day 3 of both pumps (inter-pump changes).

**Results:** Maximum blood glucose excursion (mean (SD)) was significantly higher on visit day 1;  $129.1$  mg/dL ( $38.3$ ) for PP visit 1 versus  $97.8$  ( $41.5$ ) for PP visit 2 ( $P=0.006$ ) and  $127.0$  ( $47.0$ ) for CP visit 1 versus  $96.6$  ( $31.2$ ) for CP visit 2 ( $P=0.002$ ). There was no inter-pump difference on day 1 ( $P=0.842$ ) or day 3 ( $P=0.866$ ). Average postprandial blood glucose was significantly higher on study days 1 ( $P=0.012$ );  $170.0$  mg/dL ( $47.3$ ) for PP visit 1 versus  $141.8$  ( $48.1$ ) for PP visit 2 ( $P=0.016$ ) and  $163.7$  ( $45.1$ ) for CP visit 1 versus  $141.9$  ( $37.7$ ) for CP visit 2 ( $P=0.052$ ). There was no inter-pump difference for day 1 ( $P=0.641$ ) or day 3 ( $P=0.995$ ). Time to peak glucose did not differ between study visits ( $P=0.317$ ).

**Conclusion:** Maximum blood glucose excursion and average glucose were both lower on day 3 of pump use. There were no differences between patch pumps and conventional pumps. These findings suggest that wear time plays an important role in subcutaneous insulin administration.

### Continuous subcutaneous insulin infusion is superior to subcutaneous insulin injection in the desensitisation therapy of insulin allergic diabetic patients

T. Yuan, N.S. Li, W.G. Zhao;

Department of Endocrinology, Key Laboratory of Endocrinology, Ministry of Health, Peking Union Medical College Hospital, Beijing, China.

**Background and aims:** Insulin allergy is still a major problem in the management of diabetes, although its incidence has dramatically decreased since the introduction of human insulin preparations. Immediate type IgE-mediated reactions (type I) are the most common presentation of insulin allergy. We wanted to compare two different methods in the insulin desensitisation therapy.

**Materials and methods:** We retrospectively analysed 13 cases of diabetic patients who all presented with local skin reactions after subcutaneous injection of different kinds of insulin preparations. According to the local skin reaction including the onset and disappearance time and the area of erythema, wheal, induration or pseudopodia, we selected one of the lowest reaction insulin preparations as the desensitisation insulin. Then we divided the patients into two groups accepting desensitisation therapy (continuous subcutaneous insulin infusion (CSII),  $n=5$ ; or multiple subcutaneous insulin injection,  $n=8$ ) depending on the willingness of the patients. We followed the pilot procedure in the previous treatment of insulin allergic patients in these two groups respectively. In the CSII group, the short acting insulin preparation was diluted 10 times (from U100 to U10 using saline). We used Minimed pump in all these patients. The basal rate of diluted insulin began with  $0.1$  u/h (actually was  $0.01$  u/h of insulin), then increased the basal infusion rate with  $0.1$  u per hour (actually increased with  $0.01$  u insulin per hour) in the first day of desensitisation. At the end of the first day, the basal rate would increase to  $2.4$  u/h (actually was  $0.24$  u/h). If the patient was free of any symptom of allergy, we would start the basal rate from  $0.25$  u/h in the second day (using the U100 insulin without dilution), increased the rate by  $0.05$  u per hour, till  $1.4$  u/h at the end of the second day. In the third day of desensitization, we kept the basal rate as  $1.0$  u/h or decreased to  $0.5$  u/h at night to avoid hypoglycemia in older patient, added the bolus insulin 4–6u before meal with the insulin pump. In the multiple subcutaneous insulin injection desensitisation group, The initial dose was  $0.00001$  units, with subsequent doses progressively increasing 10-fold up to 1 unit with the interval of injection was 1 hour, then 2, 4, 8, 12, 16, and 20 units. In case of local allergic reactions, the last dose was repeated until no reaction occurs and then the dose increases were continued.

**Results:** The benefit effects of CSII in the desensitisation therapy are shortening of desensitisation period (from 6.9 days to 3 days), increasing the success

rate of therapy (from 87.5% to 100%), convenient for the doctors and the nurses to operate, decreasing the discomfort of the patients and increasing the compliance of the patients.

**Conclusion:** In our observation, CSII is superior to multiple subcutaneous insulin injection by syringe in the desensitisation therapy of insulin allergic patients.

## 198

### Accuracy of a new laser technology device for the non invasive measurement of glucose in man

M. Scavini<sup>1</sup>, C. Molinari<sup>2</sup>, G.A. Di Terlizzi<sup>2</sup>, A.M. Bolla<sup>2</sup>, F. Perticone<sup>2</sup>, F. Ceriotti<sup>3</sup>, P. Trombetta<sup>4</sup>, E. Bosi<sup>1</sup>;

<sup>1</sup>Diabetes Research Institute, San Raffaele Scientific Institute, Milan, <sup>2</sup>San Raffaele Scientific Institute, Milan, <sup>3</sup>Laboraf Diagnostica e Ricerca San Raffaele, Milan, <sup>4</sup>Gulya S.r.l., Como, Italy.

**Background and aims:** A truly non invasive glucose monitoring would represent an outstanding advancement for the management of diabetes. Aim of this study was to test the accuracy of Glycolaser<sup>®</sup>, a new device for the non invasive glucose measurement based on an innovative laser technology.

**Materials and methods:** We studied male and female healthy volunteers, patients with type 1 or type 2 diabetes, patients with hypoglycemia, aged 18 to 75 yrs. Participants were studied in one occasion, either fasting or in post prandial conditions. Glycolaser<sup>®</sup> measurements were compared with plasma glucose measured with the hexokinase method on a venous blood sample drawn simultaneously. Agreement of glucose measurements with the two methods was analyzed using: a) the bias plot (ISO limits: within  $\pm 15$  mg/dl for glucose values  $< 75$  mg/dl and within  $\pm 20\%$  for glucose values  $\geq 75$  mg/dl); b) the Clarke Error Grid; and c) the Parkes Error Grid.

**Results:** We studied 171 adults aged  $47.2 \pm 16.9$  yrs, 40.4% females: 31 controls, 136 patients with type or type 2 diabetes and 4 patients with hypoglycemia. Participants were studied either fasting (n=137) or in post prandial (n=34) conditions. Forty-nine percent of Glycolaser<sup>®</sup> measurements were within the ISO limits (7.7 % for glucose levels  $< 75$  mg/dl and 52.5 % for glucose levels  $\geq 75$  mg/dl). The distribution of Glycolaser<sup>®</sup> measurements in the regions of the Clarke Error Grid was A 47.4 %; B 41.5 %; C 1.7%; D 8.2 %; E 1.2 %, with 88.9% of Glycolaser<sup>®</sup> measurements in clinically acceptable regions (A+B). The distribution of Glycolaser<sup>®</sup> measurements in the regions of the Parkes Error Grid was A 56.7 %; B 33.3 %; C 8.2 %; D 8.21.8 %; E 0 %, with 90.0 % of Glycolaser<sup>®</sup> measurements in clinically acceptable regions (A+B). Sex, age, fasting or postprandial condition did not influence the accuracy of Glycolaser<sup>®</sup> measurements.

**Conclusion:** Although the accuracy of the present device is not yet fulfilling the ISO standards, the overall performance of the non invasive Glycolaser<sup>®</sup> is not far from that of the best invasive blood glucose meters currently on the market. The improvement of the performances of the Glycolaser<sup>®</sup> prototype is expected to allow the accurate non invasive measurement of glucose in patients with diabetes in the near future.

## OP 34 Profiling glucose and clinical trials

### 199

#### Evaluation of tracking of glycaemic variability in well controlled type 2 diabetes patients: 4 years results from the ORIGIN CGM substudy

C. Koehler<sup>1</sup>, F. Schaper<sup>2</sup>, J. Steiner<sup>1</sup>, R. Staudte<sup>1</sup>, W. Landgraf<sup>3</sup>, M. Hanefeld<sup>2</sup>; <sup>1</sup>Medical Consulting, GWT-TUD GmbH, Dresden, <sup>2</sup>Center for Clinical Studies, GWT-TUD GmbH, Dresden, <sup>3</sup>Sanofi-aventis Deutschland GmbH, Frankfurt, Germany.

**Background and aims:** Continuous glucose monitoring (CGM) is an appropriate method to evaluate glycaemic variability (GV). However, there is limited information available on the tracking of CGM of an individual glucose profile. The main objective of this study was to determine whether an individual CGM profile is repeatable with stable glucose control after 4 years. **Materials and methods:** 44 T2D patients from the ORIGIN trial with a stable drug treatment for diabetes and a well-controlled HbA1c ( $< 6.2\%$ ) during follow up were included. CGM system (Medtronic) was used to measure 72h of interstitial glucose (IG) at baseline and after 4 years. Area under the curve (AUC) over 24h of the 2<sup>nd</sup> and 3<sup>rd</sup> day, 2h after testmeal (TM) at the 2<sup>nd</sup> day, peak of IG during TM, standard deviation of mean IG (SD) and mean average glucose excursions (MAGE) were calculated. In addition, anthropological data, fasting plasma glucose, HbA1c and BMI were measured.

**Results:** The correlation between baseline and 4 year follow-up (FU) of determination of MAGE and SD as best indicators of GV during CGM was statistically significant:  $R = 0.42$  for SD ( $P = 0.005$ );  $R = 0.45$  for MAGE ( $P = 0.002$ ). The same applied for HbA1c ( $R = 0.72$ ,  $P < 0.001$ ), IG 2h after TM ( $R = 0.33$ ,  $P = 0.03$ ), IG peak during TM ( $R = 0.36$ ,  $P = 0.02$ ) and 2 h-AUC after TM ( $R = 0.41$ ,  $P = 0.006$ ). These correlations indicate a stable glycaemic pattern over time. Average IG concentration and 24h-AUC were not significantly correlated between baseline and FU. In contrast, there was a small but significant increase in mean HbA1c (baseline vs. FU:  $5.70$  vs.  $5.95\%$ ,  $P < 0.001$ ), SD ( $1.25$  vs.  $1.45$  mmol/l,  $P = 0.029$ ), IG 2h after TM ( $6.60$  vs.  $7.56$  mmol/l,  $P = 0.005$ ), IG peak during TM ( $8.55$  vs.  $9.88$  mmol/l,  $P = 0.001$ ) and average IG concentration ( $6.14$  vs.  $6.57$  mmol/l,  $P = 0.017$ ).

**Conclusion:** CGM under stable conditions reveals an individual pattern of glycaemic variability in well controlled T2D patients even over longer time periods. This might be of importance for an individualized treatment of type 2 diabetes. Despite a persistent good glycaemic control, most of CGM related glycaemic determinants slightly deteriorated during 4 years of follow-up.

#### Standard deviation of glucose concentration in continuous glucose monitoring efficiently describes glycaemic variability in type 1 diabetic patients with complications

M. Prázný, J. Šoupal, M. Fajmon, J. Škrha jr., J. Škrha; Dept. of Internal Medicine 3, 1st Faculty of Medicine, Prague, Czech Republic.

**Background and aims:** Increased glycaemic variability (GV) may be associated with higher risk of microvascular complications (MVC) in Type 1 diabetes (T1DM). Continuous glucose monitoring systems are now widely available and can provide more data for the assessment of GV. Different parameters can be used for the description of GV and it is not clear which represents the best choice. The aim of the study was to compare GV in T1DM patients with and without MVC using different parameters.

**Materials and methods:** Thirty-two T1DM patients (mean age  $43 \pm 13$  yrs, duration of diabetes  $19 \pm 11$  yrs), of them 15 patients with and 17 without MVC (HbA1c  $71 \pm 9$  and  $66 \pm 13$  mmol/mol,  $p = 0.21$ , NS), participated in the study. Standard deviation (SD), coefficient of variation (CV), mean amplitude of glycaemic excursions with or without SD (MAGE and MAGE-SD) and continuous overlapping net glycaemic action with 1 and 4 hours time-intervals (CONGA-1 and -4) of glucose concentrations were calculated from CGMS records by a proprietary software. Vibration perception threshold (VPT) was measured by neurothesiometer (Bailey Instruments) and used as an estimate of diabetic neuropathy ( $0-15$  V normal,  $> 15$  V impaired VPT), retinopathy was examined by ophthalmoscopy and microalbuminuria (24hr urinary al-

bumin to creatinine ratio) was used as a marker of diabetic nephropathy. Data are mean $\pm$ SD.

**Results:** GV was higher in patients with retinopathy ( $n=13$ ) compared to patients without retinopathy (SD:  $4.1\pm0.7$  vs.  $3.4\pm0.9$ ,  $p=0.03$  and MAGE:  $7.0\pm1.1$  vs.  $5.9\pm1.4$ ,  $p=0.04$ ) although there was no significant difference in HbA1c between the groups. Similarly, GV was higher in patients with impaired VPT ( $n=12$ ) compared to the patients with normal VPT (SD:  $4.3\pm0.7$  vs.  $3.4\pm0.8$ ,  $p=0.002$ ; CV:  $0.44\pm0.06$  vs.  $0.38\pm0.07$ ,  $p=0.015$ ; MAGE:  $7.2\pm1.2$  vs.  $5.7\pm1.1$ ,  $p=0.001$ ; MAGE-SD:  $5.7\pm1.2$  vs.  $4.7\pm0.9$ ). Moreover, a positive association was observed between VPT and SD in all patients combined ( $r=0.53$ ,  $p=0.002$ ). Patients with microalbuminuria ( $n=7$ ) had significantly higher GV than patients without microalbuminuria (CV:  $0.46\pm0.07$  vs.  $0.39\pm0.07$ ,  $p=0.02$ ) even though HbA1c was nonsignificantly higher in the group without microalbuminuria ( $68\pm13$  vs.  $67\pm8$  mmol/mol, NS). In general, patients with any MVC had significantly higher GV compared to patients without complications (SD:  $4.1\pm0.7$  vs.  $3.4\pm0.9$ ,  $p=0.01$  and CV:  $0.44\pm0.06$  vs.  $0.37\pm0.07$ ,  $p=0.005$ ) although their glycemic control was comparable.

**Conclusion:** T1DM patients with any microvascular complication had significantly higher GV than the patients without complications although they did not differ in glycemic control. This finding supports the hypothesis that HbA1c may not describe the diabetes control completely and accurately. We conclude that SD represents an easy estimate of glycemic variability and in comparison with other more complex parameters it performs very well.

### Racial and ethnic differences in mean blood glucose, HbA<sub>1c</sub>, and estimated average glucose in patients with type 2 diabetes

B.H.R. Wolffenbuttel<sup>1</sup>, W.H. Herman<sup>2</sup>, H.H. Jiang<sup>3</sup>, M.A. Carey<sup>4</sup>, D.S. Hardin<sup>3</sup>

<sup>1</sup>University Medical Center, Groningen, Netherlands, <sup>2</sup>University of Michigan, Ann Arbor, USA, <sup>3</sup>Lilly USA, LLC, Indianapolis, USA, <sup>4</sup>PharmaNet/i3, Blue Bell, USA.

**Background and aims:** Recent studies have reported HbA1c differences across racial/ethnic groups. The A1C-Derived Average Glucose (ADAG) study recommended reporting HbA1c in estimated average glucose (eAG) equivalents. We aimed to assess the relationship between HbA1c and self-monitored mean blood glucose (SMBG) in different racial/ethnic groups, and to compare eAG with SMBG to determine whether the use of eAG is acceptable and feasible in different ethnic groups with type 2 diabetes.

**Materials and methods:** The DURABLE trial assessed the differences between 2 insulin starter regimens, and enrolled 2091 patients with type 2 diabetes, ages 30–80, from 11 countries. Full data are available for this analysis at baseline and after stabilisation of glycaemic control 6 months after initiation of insulin therapy, in the following racial/ethnic groups: Caucasian ( $n=1241$ , 63.9%), Asian ( $n=304$ , 15.7%), Hispanic ( $n=225$ , 11.6%), African Descent ( $n=109$ , 5.6%), and Other ( $n=62$ , 3.2%; not shown). A population regression equation was calculated for all racial subgroups using the mean of all SMBG values and mean HbA1c for each group. eAG was calculated from the ADAG linear regression equation. A mean blood glucose index (MBGI) was calculated as the difference between mean blood glucose (MBG) and eAG.

**Results:** Baseline mean  $\pm$  SD HbA1c was  $9.0 \pm 1.3\%$ , and MBG (via 7-point SMBG profile) was  $12.1 \pm 3.1$  mmol/l. There was a linear relationship between HbA1c and SMBG in all racial/ethnic groups, but for a given MBG, HbA1c was 0.3 and 0.4% higher in Hispanic patients and people of African Descent, respectively, compared to Caucasians. At MBG levels  $<11$  mmol/l, eAG overestimated the actual average blood glucose (BG), and at levels  $>11$  mmol/l, eAG underestimated the actual BG levels (Figure 1).

**Conclusion:** For a certain degree of glycaemia, actual HbA1c levels vary between the different racial/ethnic groups. eAG, calculated from HbA1c, is not a reliable surrogate for actually measured BG levels, and is therefore of limited clinical use.

Figure 1 Relationship between mean blood glucose index (MBGI) and mean of all blood glucose (BG) values

Clinical Trial Registration Number: NCT00279201

## 202

### Monnier's hypothesis revisited: postprandial (PPG) vs fasting (FPG) hyperglycaemia at baseline and response to basal or premixed insulin stratified by HbA<sub>1c</sub> target achieved

A.J. Scheen<sup>1</sup>, J. Rosenstock<sup>2</sup>, H. Schmitt<sup>3</sup>, H.H. Jiang<sup>4</sup>, T. Ivanyi<sup>5</sup>

<sup>1</sup>CHU Liege, University of Liege, Belgium, <sup>2</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA, <sup>3</sup>Eli Lilly, Brussels, Belgium, <sup>4</sup>Eli Lilly, Indianapolis, USA, <sup>5</sup>Eli Lilly, Budapest, Hungary.

**Background and aims:** Monnier's cross-sectional study in Type 2 Diabetes (T2D), using 4-point glycaemic profiles during daytime, showed a greater contribution of PPG vs FPG to overall hyperglycaemia at lower HbA<sub>1c</sub>. We challenged this hypothesis, using a 24h glycaemic profile and comparing effect of a basal insulin, insulin glargine (G;  $n=1046$ ) with a premix insulin with a prandial component, insulin lispro mix 25 (25% insulin lispro, 75% insulin lispro protamine suspension, LM25;  $n=1045$ ).

**Materials and methods:** In the initiation phase of DURABLE study [T2D on  $\geq 2$  OADs], patients were randomized to once-daily G or twice daily LM25 for 24 weeks. Relative 24h contributions of PPG and FPG to overall hyperglycaemia were calculated from 7-point glucose profiles with Area Under the Curve (AUC) for FPG between 100 mg/dL and fasting glycaemia and for PPG above the line projected from fasting glycaemia.

**Results:** At baseline, with increasing HbA<sub>1c</sub>, contributions of FPG to total AUC increased from 59 to 73% and PPG decreased from 41 to 27% (Figure 1). FPG AUC increased linearly with HbA<sub>1c</sub> while PPG AUC increased only slightly. At endpoint, both LM25 and G lowered FPG AUC but only LM25 lowered PPG AUC. Below 8% and between 8–9% HbA<sub>1c</sub> at baseline, LM25 allowed a significantly higher % of patients to reach target  $<7\%$  HbA<sub>1c</sub> vs G (72 vs 62% and 52 vs 43%, respectively). Similar % of patients reached target HbA<sub>1c</sub> with LM25 and G in quartiles HbA<sub>1c</sub> 9–10% (31 vs 28%) and  $\geq 10\%$  (28 vs 25%). Comparison of patients reaching target, or not, per quartile, showed baseline HbA<sub>1c</sub>, FPG and FPG AUC were similar but decreases were greater in those reaching target, allowing lower endpoint values. The higher the HbA<sub>1c</sub> baseline quartile, the greater was the absolute decrease in HbA<sub>1c</sub> for both insulins. Patients with baseline HbA<sub>1c</sub>  $<8\%$ , not reaching target with both insulins, had a higher % of PPG AUC at baseline ( $\sim 49$  vs  $\sim 37\%$ ), suggesting they could benefit from an insulin regimen with a higher prandial percentage or higher insulin doses. Patients not reaching target had a slightly higher insulin dose but lower rate of hypoglycaemia, suggesting insulin resistance, and possibly, an unwillingness to increase dose further and/or poor compliance to lifestyle and the insulin regimen.

**Conclusion:** At baseline, the relative contribution of PPG vs FPG decreased with higher HbA<sub>1c</sub>, confirming Monnier's findings, and with a relevant role of PPG only at lower HbA<sub>1c</sub> and hence a higher % of patients reaching target with LM25 at low HbA<sub>1c</sub> quartiles. However, FPG AUC predominated at all HbA<sub>1c</sub> quartiles and was potentially amenable to further improvements. In all HbA<sub>1c</sub> quartiles, there was a lower decrease in FPG and FPG AUC in patients

above target, suggesting that insulin dose could be increased further or then patients need to be advanced to more intensive regimens.

**Figure 1: AUC FPG vs. AUC PPG at Baseline for all Randomized Patients (N=1897)**

## 203

### The extent of and variation in mortality among inpatients with diabetes

N. Holman;

Diabetes Health Intelligence, Yorkshire and Humber Public Health Observatory, York, UK.

**Background and aims:** It is known that people with diabetes have higher hospital admission and mortality rates than their peers. However, little is known about the relative risk of inpatient mortality among patients whether local variation is due to different patient populations and/or in healthcare services. This work aimed to assess the additional risk of dying amongst inpatients with diabetes and hospital variation in this risk across England.

**Materials and methods:** The record of all hospital admissions (Hospital Episode Statistics) was used to identify all hospital admissions between April 2009 and March 2011. Admissions relating to pregnancy, childbirth, babies born in hospital and those in specialist hospitals were excluded. Binary regression models were used to assess the impact of age, sex, social deprivation, method of admission, reason for admission and type of hospital on the odds of dying nationally and for individual hospital trusts. Two hospital level standardised mortality ratios were calculated - one compared in the hospital trust to all inpatients with diabetes in England and one adjusted for the pattern of mortality among inpatients without diabetes in the same hospital trust. The former standardised mortality ratio was correlated with a national measure of all cause hospital mortality (Summary Hospital-level Mortality Indicator or SHMI).

**Results:** A total of 13,150,750 hospital admissions in 148 hospital trusts meet the inclusion criteria. Of these 1,474,363 (11.2%) were in patients with diabetes. The crude mortality rate was 4.9% for inpatients with diabetes compared to 3.0% for those without diabetes (additional risk 76.2%). Adjusting for age and sex reduced the additional risk of death to 14.4% ( $p < 0.005$ ). Adding method of admission, reason for admission and the type of hospital further reduced the additional risk to 9.9% ( $p < 0.005$ ). When patients were split into quintiles based on the social deprivation score of their home postcode, there was a clear social deprivation gradient in the adjusted risk of death for inpatients without diabetes after adjustment for age, sex, method of admission, reason for admission and type of hospital trust (RR compared to least deprived quintile - 1.099, 1.084, 1.056 and 1.045, all  $p < 0.005$ ). However, there was no clear gradient amongst inpatients with diabetes (RR compared to least deprived quintile - 0.964  $p = 0.384$ , 1.005  $p = 0.108$ , 1.024  $p < 0.005$ , 1.025  $p < 0.005$ ). When mortality among inpatients with diabetes was compared to England 23 hospital trusts (15.5%) were above the 95% CI and 8 (5.4%) were above the 99.9% CI. There was a significant positive correlation between the mortality ratio standardised to all inpatients with diabetes in England and SHMI ( $r = 0.674$ ,  $r^2 = 0.451$ ,  $p < 0.005$ ). When mortality among inpatients with diabetes is standardised using patients without diabetes from the same hospital variation persists with five (3.4%) hospital trusts having ratios above the 95% CI and 13 (8.8%) having ratios lower than the 95% CI.

**Conclusion:** This analysis found that inpatients with diabetes had a 9.9% higher risk of mortality (after case mix adjustment) than inpatients without diabetes. Unlike those without diabetes, there was no social deprivation gradient in inpatient mortality among inpatients with diabetes. Some of the variation (45%) in inpatient mortality among those with diabetes can be explained by the pattern of all cause mortality but when local adjustments are made some hospital trusts show significantly different mortality ratios.

### State of diabetes-related trials in the clinicaltrials.gov dataset

J.B. Green<sup>1,2</sup>, W. Lakey<sup>1,2</sup>, K. Barnard<sup>1,2</sup>, B. Batch<sup>1,2</sup>, M. Bethel<sup>3,4</sup>, K. Chiswell<sup>5</sup>, A. Tasneem<sup>5</sup>;

<sup>1</sup>Division of Endocrinology, Metabolism, and Nutrition, Duke University Medical Center, Durham, USA, <sup>2</sup>Durham Veterans Affairs Medical Center, USA, <sup>3</sup>Diabetes Trials Unit, University of Oxford, UK, <sup>4</sup>Duke University Medical Center, Durham, USA, <sup>5</sup>Duke Clinical Research Institute, Durham, USA.

**Background and aims:** Trials which assess interventions to prevent diabetes and its complications and enhance our ability to care for all affected are needed. It is unclear if the scope of current clinical trials will adequately address deficiencies in our understanding of diabetes care.

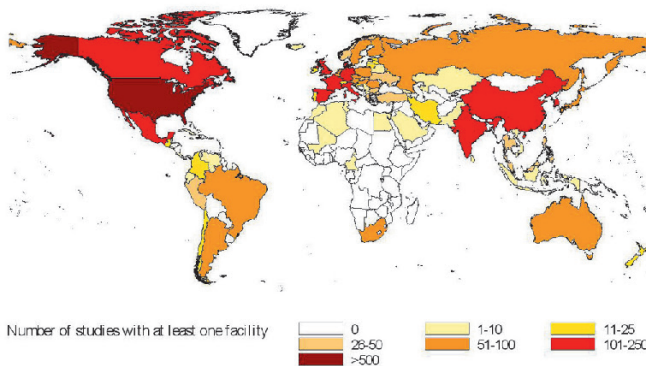

**Materials and methods:** ClinicalTrials.gov is a registry which contains information entered by sponsors and investigators conducting clinical trials in the US and around the world. A dataset of 96,346 studies registered in ClinicalTrials.gov was downloaded on September 27, 2010. The diabetes study subset of 2,484 interventional trials was created by selecting those trials with relevant disease condition terms. The set of terms chosen was intentionally broad in order to capture trials enrolling patients with diagnosed diabetes as well as related conditions such as pre-diabetes or insulin resistance.

**Results:** Diabetes-related trials comprised 4.8% of the 40,970 interventional trials overall. 74.8% of the diabetes trials had a primarily therapeutic purpose while 10% had a preventative purpose. Listed interventions included drugs (63.1%) and behavioral (11.7%). Most trials were to enroll  $\leq 500$  (91%) or  $\leq 100$  (58.6%) subjects, with mean/median times to completion of 1.8/1.4 years. Small percentages of trials targeted individuals aged 18 or younger (3.7%) or 65 or older (0.6%), while 30.8% excluded patients older than 65 and the majority excluded those over 75. Funding included industry (50.9%), NIH (7.5%), or other with most being single-center trials of other sponsorship (37.7%) or industry-funded multi-center studies (27.4%). Of the 2500 primary outcomes listed in free text, 51 (0.02%) included mortality or significant cardiovascular complications such as myocardial infarction or stroke. Regions where studies had facilities included North America (56.1%), Europe (33.5%), Eastern Asia (13.5%), and South America (7%). 40.5% of trials had facilities in only the US, 49.7% were outside the US, and 9.8% were conducted in the US and other regions. Distribution of diabetes trials by country is outlined in the attached figure.

**Conclusion:** The majority of diabetes-related trials include relatively small numbers of patients, exclude those at extremes of age, are of short duration, involve drug therapy rather than studying prevention or non-drug interventions, and do not focus upon significant cardiovascular outcomes. The distribution of trials does not correlate with the prevalence of diabetes in many countries, perhaps most notably in the Middle East, Latin America, Southern Africa, and the Russian Federation. Recently registered diabetes trials may not sufficiently address important diabetes care issues or involve affected populations.

### 205

**Adipocyte-specific deletion of Janus kinase 2 (JAK2) leads to increased adiposity, reduced energy expenditure and age-dependent glucose intolerance**

S.Y. Shi<sup>1,2</sup>, C.T. Luk<sup>1,2</sup>, S.A. Schroer<sup>2</sup>, K.-U. Wagner<sup>3</sup>, M. Woo<sup>2,4</sup>;

<sup>1</sup>Institute of Medical Science, University of Toronto, Canada, <sup>2</sup>Toronto General Research Institute, University of Toronto, Canada, <sup>3</sup>University of Nebraska Medical Center, Omaha, USA, <sup>4</sup>Department of Medicine, St. Michael's Hospital, Toronto, Canada.

**Background and aims:** Adipocytes were once thought to be inert energy storage depots, but are now recognized as active endocrine cells that secrete hormones and cytokines to regulate energy balance and metabolic homeostasis. Alterations in adipocyte development and/or function have been implicated in the pathophysiology of metabolic diseases, particularly type 2 diabetes. A better understanding of adipocyte biology is therefore crucial given the growing worldwide epidemic of obesity and diabetes. The Janus kinase-signal transducer and activator of transcription (JAK-STAT) pathway mediates signal transduction of numerous cytokines and hormones that regulate adipocyte development and function. Several adipokines secreted by adipocytes also utilize this signaling pathway, illustrating the physiological importance of JAK-STATs in adipocyte biology. This study aims to investigate the metabolic roles of JAK2 in adipocytes.

**Materials and methods:** We utilized an *in vivo* genetic approach and generated mice with deletion of JAK2 specifically in fat cells (F-JAK2 KO) by breeding mice with their *Jak2* gene flanked by loxP sites with mice expressing the *Cre* recombinase driven by the aP2 promoter.

**Results:** F-JAK2 KO mice gradually gained more body weight on a chow diet starting at 2 months of age, and by 5 months, they weighed about 60% more than control littermates ( $p < 0.001$ ). Relative weight of isolated subcutaneous, visceral and brown fat pads from 24-30-week-old F-JAK2 KO mice was 2 to 6 fold higher than controls, suggesting that the higher body weight in F-JAK2 KO mice was due to increased adiposity. Next, we placed mice individually in metabolic chambers to measure their energy balance status. We found no difference in absolute daily food intake ( $2.25 \pm 0.36$  in F-JAK2 KO vs  $2.07 \pm 0.23$  g/day in controls;  $p = 0.72$ ). F-JAK2 KO mice were also comparable to controls in terms of the fuel source utilized, as evidenced by a similar respiratory exchange ratio. On the other hand, rates of  $O_2$  consumption and  $CO_2$  production were about 30% lower in F-JAK2 KO mice ( $p < 0.001$ ), consistent with reduced energy expenditure. This may be explained, at least in part, by reduced physical activity ( $p < 0.05$ ). We next determined the metabolic consequences of adipocyte JAK2 deletion. At 2 months of age, despite being significantly obese, F-JAK2 KO mice did not display abnormalities in fasting blood glucose ( $3.9 \pm 0.5$  in F-JAK2 KO vs  $4.0 \pm 0.4$  mM in controls;  $p = 0.86$ ), glucose tolerance or insulin sensitivity. Even at 4-6 months of age, F-JAK2 KO mice maintained normal levels of random and fasting blood glucose. However, when given an i.p. glucose challenge, they appeared to be more intolerant than controls (AUC  $1392.0 \pm 193.1$  in F-JAK2 KO vs  $913.2 \pm 40.7$  in controls;  $p < 0.05$ ) and there was also a trend towards reduced insulin sensitivity as demonstrated by i.p. insulin tolerance test.

**Conclusion:** Taken together, our results implicate a critical role of JAK2 in regulation of adipocyte biology and whole-body glucose metabolism. Targeting the JAK-STAT pathway may therefore provide a novel therapeutic strategy for the treatment of type 2 diabetes.

**Essential role of adipocyte focal adhesion kinase in mediating insulin resistance**

C.T. Luk<sup>1,2</sup>, S.Y. Shi<sup>1,2</sup>, E.P. Cai<sup>1,2</sup>, T.S. Sivasubramaniam<sup>2</sup>, S.A. Schroer<sup>2</sup>, M. Woo<sup>2,3</sup>;

<sup>1</sup>Institute of Medical Science, <sup>2</sup>Toronto General Research Institute,

<sup>3</sup>Department of Medicine, Toronto, Canada.

**Background and aims:** Adipose tissue extracellular matrix (ECM) has recently been shown to be important in whole body glucose homeostasis but little is known about the mechanism by which signals from the ECM are

translated into adipocytes. Focal adhesion kinase (FAK) is a ubiquitously expressed tyrosine kinase involved in integrin signalling and essential for development and proliferation. Interestingly, inhibition of FAK has been implicated in insulin resistance by studies showing that disruption of FAK in hepatocytes and myocytes impairs glycogen production and actin-mediated GLUT4 translocation. Although FAK has been shown to be phosphorylated in response to insulin in adipocyte cell lines, its role in adipocyte glucose homeostasis and energy metabolism has not been established. The aim of this study was to assess the role of adipocyte FAK in insulin resistance.

**Materials and methods:** To generate a novel adipose-specific FAK knock-out mouse (*aP2Cre<sup>+</sup>FAK<sup>fl/fl</sup>*), transgenic mice with adipocyte protein 2 (*aP2*) promoter-driven CRE recombinase expression in adipocytes were crossed with *FAK<sup>fl/fl</sup>* mice. To further investigate the role of FAK in the setting of diabetes and obesity, at 8 weeks of age, *aP2Cre<sup>+</sup>FAK<sup>fl/fl</sup>* mice were placed on high-fat diet for 16 weeks.

**Results:** By 12 weeks of age, *aP2Cre<sup>+</sup>FAK<sup>fl/fl</sup>* mice on chow diet had higher fasting blood glucose levels than wild-type littermate controls ( $7.4 \pm 0.4$  vs  $5.6 \pm 0.7$  mmol/L,  $n=9$ ,  $p<0.05$ ) despite no difference in total body weight. While glucose tolerance was preserved on intraperitoneal glucose tolerance testing, *aP2Cre<sup>+</sup>FAK<sup>fl/fl</sup>* were more insulin resistant on insulin tolerance testing ( $p<0.05$ ), and had higher fasting insulin levels ( $0.73 \pm 0.11$  vs  $0.35 \pm 0.06$  ng/mL,  $n=4$ ,  $p<0.05$ ). Similarly, leptin gene expression and serum leptin levels were increased (5.4-fold,  $n=7$ ,  $p<0.05$ ;  $1.58 \pm 0.12$  vs  $0.83 \pm 0.06$  ng/mL,  $n=6$ ,  $p<0.05$ ). Analysis of body composition by necropsy showed increased white adipose tissue fat pad weight (+71% for perigonadal fat pad,  $n=4$ ,  $p<0.05$ ). Differences in body composition could not be accounted for by differences in energy homeostasis, as measured by food intake, ambulatory activity, respiratory exchange ratio or oxygen consumption. However, sterol regulatory element binding protein-1c (SREBP-1c) and macrophage-specific F4/80 gene expression were increased (2.9-fold,  $n=7$ ,  $p<0.05$ ; 2.6-fold,  $n=7$ ,  $p<0.05$ ). Surprisingly, on high-fat diet, *aP2Cre<sup>+</sup>FAK<sup>fl/fl</sup>* mice continued to be insulin resistant but had 29% lower body weight ( $n=5$ ,  $p<0.05$ ), suggesting impairment of FAK may contribute to impaired adipocyte growth, reminiscent of lipodystrophy.

**Conclusion:** Overall, knockdown of adipocyte FAK resulted in insulin resistance and increased adiposity under basal conditions but decreased weight gain on high-fat diet. These results demonstrate a new and important role for FAK in adipocyte mediation of adiposity and whole body insulin sensitivity. *Supported by: CIHR MOP-191501, CDA Grant-in-Aid and BBDC*

## 207

### Mice with beta cell specific overexpression of CART exhibit altered adipocyte lipid metabolism

E. Banke<sup>1</sup>, M. Riva<sup>2</sup>, M. Ländin<sup>2</sup>, A.-H. Thorén Fischer<sup>2</sup>, E. Degerman<sup>1</sup>, N. Wierup<sup>2</sup>

<sup>1</sup>Experimental Medical Sciences, Lund, <sup>2</sup>Clinical Sciences in Malmö, Sweden.

**Background and aims:** Cocaine and amphetamine regulated transcript (CART) is a regulatory peptide expressed in the central and peripheral nervous systems, as well as in the pancreatic islets. CART deficient mice exhibit islet dysfunction, impaired insulin secretion and increased body weight. On the other hand, islet CART is upregulated in type 2 diabetes patients and in animal models of type 2 diabetes. Our recent studies showed that CART is expressed also in human and rodent adipocytes and that CART affects several processes important for adipocyte function. Depending on the hormonal context, the effects of CART are insulin-like or insulin antagonistic. The aim of this study was to investigate the effect of increased levels of CART on adipocyte lipid metabolism.

**Materials and methods:** To study the consequence of an increased expression of CART in beta cells on whole body metabolism, transgenic mice with beta cell-specific (under the control of the PDX-1 promoter) overexpression of CART (CARTtg) was constructed. Characterisation of the CARTtg mice is ongoing. Here we focus on the effects of increased levels of CART on adipocyte lipid metabolism. Primary adipocytes from wild type and CARTtg mice, kept on either control or high fat diet, were isolated and lipolysis was measured after stimulation with the beta adrenergic receptor agonist isoprenaline with or without insulin.

**Results:** CARTtg mice both in the control and high fat diet group displayed significantly lower basal lipolysis compared to wild type mice. Also, CARTtg mice were more responsive to isoprenaline-induced lipolysis in both diet groups. Furthermore, the ability of insulin to inhibit lipolysis was improved in CARTtg mice on control diet compared to wild type mice. These data are in agreement with recent in vitro studies in rat adipocytes using exogenous CART.

**Conclusion:** Our data suggest a role for CART in cross talk between beta cells and adipocytes. Elevated levels of CART in beta cells alters adipocyte lipid metabolism by making them more responsive to adrenergic stimuli as well as enhancing adipocyte insulin sensitivity. Ongoing studies are investigating whether CART levels are also increased systemically.

### RB1 mRNA, protein and activity in association with adipogenic capacity of human adipose tissue

J.M. Moreno-Navarrete<sup>1</sup>, P. Petrov<sup>2</sup>, M. Serrano<sup>1</sup>, F. Ortega<sup>1</sup>, J. Ribot<sup>2</sup>, W. Ricart<sup>1</sup>, A. Palou<sup>2</sup>, M. Bonet<sup>2</sup>, J. Fernández-Real<sup>1</sup>

<sup>1</sup>Hospital of Girona, <sup>2</sup>Universitat de les Illes Balears, Palma de Mallorca, Spain.

**Background and aims:** Retinoblastoma (Rb1), the extensively known tumor suppressor gene, has been described as an essential player in mouse white adipocyte differentiation, being a negative modulator of brown adipocyte differentiation. To our knowledge, no studies have explored Rb1 in human adipose tissue or adipocytes. We aimed to investigate retinoblastoma protein family [RB1, RBL2 (p130) and RBL1 (p107)] in human adipose tissue and adipocytes according to obesity and insulin sensitivity.

**Materials and methods:** RB1, RBL2 and RBL1 gene expressions (Real Time PCR) were analysed in two independent cohorts, in 154 adipose tissue samples (77 visceral and 77 subcutaneous depots) from participants with different degrees of obesity and in a second cohort of 64 adipose tissues (32 visceral and 32 subcutaneous depots) from morbidly obese participants with different degrees of insulin action (measured with euglycemic clamp). The expression of these genes also was studied during human and 3T3-L1 (mouse cell line) adipocyte differentiation in a time course experiment. Rb activity was calculated measuring  $\text{phospho}^{\text{Thr821}}\text{Rb}$  and  $\text{total Rb}$  in adipose tissue samples and during adipogenesis. Finally, the effects of Rb knockdown in differentiated 3T3-L1 adipocytes were tested using two different methods (permanent silencing with lentiviral particles and transient silencing with electroporation).

**Results:** RB1 and RBL2 gene expressions were negatively associated with BMI in both visceral (VAT) and subcutaneous (SAT) adipose tissues and positively associated with PPAR $\gamma$  and IRS1. In SAT, these genes were also negatively associated with leptin and positively with FASN and ACC gene expression. RBL1 gene expression was not associated with metabolic parameters. Similar to RB1 gene expression, RB1 protein levels and activity in adipose tissue decreased in association with obesity. Interestingly, RB1 was negatively associated with fasting insulin and HOMA $_{\text{IR}}$ . RB1 and RBL2 increased significantly during adipocyte differentiation in parallel to adipogenic genes. RBL1 tended to decrease during adipocyte differentiation. RB1 permanent knockdown (60%) decreased adipogenic gene expression (PPAR $\gamma$ , adiponectin, FASN, ACC, CEBP $\alpha$ , FABP4, IRS1 and GLUT4) whereas increased brown-like adipocyte related genes (PRDM16 and UCP1) during adipocyte differentiation. RB1 transient knockdown (65%, 32 h), in fully differentiated adipocytes led to loss of the adipogenic phenotype, decreasing significantly PPAR $\gamma$ , adiponectin, FASN and FABP4 gene expression, while no effects were observed in brown-like adipocyte related genes.

**Conclusion:** To the best of our knowledge, this is the first study showing a strong relationship among RB1, RBL2 and adipogenesis in human adipose tissue and adipocytes, being RB1 mRNA, protein level and activity decreased in association with obesity. RB1 permanent knockdown confirmed findings in knockout mice which showed the role of RB1 on white adipocyte differentiation. In addition, RB1 was necessary to maintain adipogenic characteristics in fully differentiated adipocytes.

## 209

**Visceral fat accumulation during overfeeding is related to subcutaneous adipose tissue characteristics in humans**

M. Laville<sup>1,2</sup>, M. Alligier<sup>1,3</sup>, L. Gabert<sup>1,4</sup>, E. Meugnier<sup>4,5</sup>,  
S. Lambert-Porcheron<sup>5,6</sup>, B. Morio<sup>6,7</sup>, A. Vidal Puig<sup>7</sup>, H. Vidal<sup>8</sup>;

<sup>1</sup>Lyon 1 University, Pierre-Bénite, France, <sup>2</sup>University of Cambridge, UK, <sup>3</sup>CRNH Auvergne, Clermont-Ferrand, France, <sup>4</sup>Inserm U MR 1060 CARMEN, Oullins, France, <sup>5</sup>CRNH RA, Pierre-Bénite, France, <sup>6</sup>INRA UMR1019, Clermont-Ferrand, France, <sup>7</sup>Institute of Metabolic Science, Cambridge, UK, <sup>8</sup>Inserm U MR 1060 CARMEN, Pierre-Bénite, France.

**Background and aims:** The hypothesis of a limited expansion of subcutaneous adipose tissue during weight gain provides an attractive explanation for the reorientation of excess lipids towards ectopic sites, contributing to metabolic complications. We investigated how the characteristics of subcutaneous adipocytes influence the partition of lipids towards abdominal fat depots during an experimental overfeeding

**Materials and methods:** A 56 day overfeeding (+760 Kcal/day) experiment was realised in 41 healthy non-obese volunteers. Abdominal adipose tissue depot volume was determined by MRI and postprandial fatty acids spill-over was measured during test meal labelled with [d31]-deuterated palmitic acid. Gene expression was realised in sub-cutaneous adipose tissue biopsies by RT-PCR

**Results:** Overfeeding led to a  $2.5 \text{ Kg} \pm 0.2$  ( $p = 0.001$ ) weight gain. Both abdominal subcutaneous ( $+14 \pm 2\%$ ,  $p = 0.001$ ) and visceral ( $+22 \pm 5\%$ ,  $p = 0.001$ ) increased significantly during overfeeding but with large interindividual variations in the volume. There was no relationship between the relative expansion of these two fat depots, but the increased in visceral fat was positively associated with the magnitude of the postprandial fatty acid spill-over (AUCTION-T300 :  $r = 0.66$ ,  $p = 0.02$ ). The regulation of lipid storage-related genes (SREBP1C, DGAT2 and CIDEA) was defective in the subcutaneous fat of the subjects exhibiting the largest accumulation in visceral depot. Conversely, high subcutaneous fat gainers had increased induction of lipogenic genes and down-regulation of the lipolytic genes HSL and ATGL in their subcutaneous fat.

**Conclusion:** We demonstrate that the partition of lipids towards the abdominal fat depots during overfeeding in non-obese subjects is associated with molecular and functional characteristics of the subcutaneous adipose tissue. These results lend support to the adipose tissue expandability theory and provide evidence that defects in adipose tissue expandability can be detected early on during the evolution towards obesity with proper functional challenges. Further studies are now required to validate that controlled metabolic challenges such as overfeeding and lipid tolerance tests could provide new insights for the identification of subjects at risk of obesity complications.

**RBP4 and its membrane receptor stra6 control adipogenesis by regulating cellular retinoid homeostasis**

M. Schupp<sup>1</sup>, J. Raila<sup>2</sup>, N. Witte<sup>1</sup>, N. Tuvia<sup>1</sup>, M. Muenzner<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Diabetes, and Nutrition, Charité-University Medicine Berlin, <sup>2</sup>Department of Physiology and Pathophysiology, University of Potsdam, Germany.

**Background and aims:** The understanding of adipocyte differentiation has important implications for the treatment of obesity. Retinoids inhibit adipogenesis by activating the retinoic acid receptor (RAR)  $\alpha$ . However, the physiologic regulation of retinoid levels in precursor cells is largely unknown. We investigated the function of retinol-binding protein (RBP) 4 and its recently identified membrane receptor stra6 during adipocyte differentiation.

**Materials and methods:** We applied cellular gain-and loss-of-function studies to adipocyte precursor cells by electroporation of siRNA and retroviral overexpression of stra6. Furthermore, cells were differentiated in the presence of retinol-bound (holo) or unbound (apo) recombinant RBP4 protein produced in *E. coli*. Cellular retinoid levels were determined by HPLC. RAR  $\alpha$  activity was assessed by the electroporation of luciferase-coupled reporter constructs. The expression of RAR  $\alpha$  target-genes was measured by qPCR.

**Results:** We found that the RBP4 membrane receptor stra6 protein is expressed in preadipocytes and increases during differentiation. Depletion of stra6 in precursor cells inhibited, whereas stra6 over-expression enhanced

differentiation. These effects were dependent on retinol/ RBP4, suggesting that stra6 regulates RAR  $\alpha$  ligand availability. Accordingly, RBP4 reduced cellular retinoid levels, RAR  $\alpha$  activity and its target-gene expression, and enhanced differentiation in a stra6 dependent manner only when present in its retinol-free apo-form. Holo-RBP4, in contrast, induced RAR  $\alpha$  target-genes and blocked differentiation.

**Conclusion:** Our data demonstrate opposing effects of apo- and holo-RBP4 on differentiation and show that RAR  $\alpha$ -activating retinoids in precursor cells need to efflux via a stra6/apo-RBP4 dependent mechanism for adipogenesis to occur. These findings reveal an important metabolic aspect of the retinoid homeostasis that may help us to develop novel retinoid- and RBP4-based therapies to treat obesity and type 2 diabetes.

### Role of the microRNA miR-338-3p in compensatory beta-cell mass expansion during pregnancy and obesity

C. Jacovetti<sup>1</sup>, A. Abderrahmani<sup>2</sup>, R. Regazzi<sup>1</sup>;<sup>1</sup>Department of Cell Biology and Morphology, Lausanne, Switzerland,<sup>2</sup>Institut Européen de Génomique de Lille, France.

**Background and aims:** Pregnancy and obesity are associated with insulin resistance and increased insulin needs. To preserve glucose homeostasis, the rise in insulin demand is compensated by expansion of the pancreatic  $\beta$ -cell mass. The molecular mechanisms underlying this phenomenon are still poorly understood. microRNAs constitute a large class of non-coding RNAs that play major roles in the control of gene expression by partially pairing to the 3'UTR of target mRNAs thereby inhibiting their translation and/or stability. The aim of this project is to determine the role played by microRNAs in compensatory  $\beta$ -cell expansion in a context of insulin resistance.

**Materials and methods:** We used expression profiling methods to search for changes in the level of microRNAs in the islets of insulin resistant animal models. Differential microRNA expression was verified by quantitative real-time PCR. The functional impact of selected microRNAs on insulin secretion, cell proliferation and survival was studied by modifying their expression in the insulin-secreting cell lines MIN6 and INS832/13 and in dissociated rat and human islet cells. Real-time PCR was used to determine the mechanisms regulating the levels of the microRNAs and of the genes controlled by the microRNAs.

**Results:** We identified a microRNA, miR-338-3p, which is down-regulated in the islets of different animal models displaying compensatory  $\beta$ -cell mass expansion such as pregnant rats, high fat fed mice and 6-week-old obese *db/db* mice. We found that reduction of miR-338-3p expression in rat and human islets could be achieved by incubation with estradiol or with the GLP-1 analogue exendin-4. Specific inhibition of miR-338-3p activity increased the fraction of proliferating  $\beta$ -cells, and promoted  $\beta$ -cell survival in the presence of apoptotic stimuli without affecting the capacity of the cells to release insulin in response to glucose. Moreover, knock-down of miR-338-3p in rat and human islet cells resulted in a decrease in the expression of apoptotic genes and up-regulation of anti-apoptotic and pro-proliferative genes.

**Conclusion:** We showed that blockade of miR-338-3p, a microRNA which is decreased in islets of animals displaying insulin resistance, permits to increase proliferation and survival of  $\beta$ -cells, suggesting its potential contribution to  $\beta$ -cell mass expansion associated to pregnancy and obesity. Our data could pave the way for the development of new microRNA-based strategies aiming at promoting the  $\beta$ -cell regenerative capacities and at preserving an appropriate functional  $\beta$ -cell mass.

### An islet-specific long non-coding RNA (lncRNA) expressed from the Pdx1 locus regulates Pdx1 activity

T.J. Pullen, G.A. Rutter;

Cell Biology / Div. Diabetes, Endocrinology &amp; Metabolism, Imperial College London, UK.

**Background and aims:** Maintained expression of Pancreatic and duodenal homeobox 1 (*Pdx1*) is required for normal beta cell function, as reflected by the defects in insulin secretion caused by *Pdx1* haploinsufficiency in MODY4 patients and mouse models. Although much work has elucidated a network of transcription factors regulating *Pdx1* expression, there is evidence that epigenetic factors around the *Pdx1* promoter can downregulate its expression, consequently interfering with beta cell function. There is also increasing evidence that long non-coding RNAs (lncRNAs) can interact with chromatin modifying complexes to target epigenetic marks to particular genomic loci. We therefore aimed to identify lncRNAs expressed in islets from the loci of transcription factors important for islet development and function, and determine whether they can regulate the expression of the corresponding protein-coding gene.

**Materials and methods:** Predicted non-coding transcripts arising <5 kb from key islet transcription factor loci were identified in the mouse genome

(Ensembl release 57). Expression levels of these lncRNAs and corresponding transcription factor mRNAs were determined using high-throughput RNA sequencing (RNA-seq) data of islets prepared from five C57Bl/6 mice. The lncRNA from the *Pdx1* locus (*Pdx1-asRNA*) was cloned by RT-PCR from mouse islet RNA, and three shRNAs were designed to target it. The effect of expressing cDNA of, or shRNA against *Pdx1-asRNA* on endogenous *Pdx1* activity was assayed in the MIN6 beta cell line by luciferase reporter assay using a 6xSMS-TAAT1 element.

**Results:** Of eight transcription factor/lncRNA pairs for which expression data were available, four showed clear expression of both mRNA and lncRNA in mouse islets (*Pdx1*, *Nkx2.2*, *Pax6*, *Hnf1a*). Consistent with previous reports of the relatively low abundance of lncRNAs, the expression levels of these lncRNAs was substantially lower than the corresponding mRNA at  $13 \pm 2\%$  (mean  $\pm$  SEM,  $n=4$ ). Of the remaining loci, one (*Foxa2*) showed substantial expression of the mRNA (>30 RPKM [Reads Per Kilobase of exon model per Million mapped reads]) but not lncRNA (<2 RPKM). The other three transcription factors (*Hnf1b*, *Ptf1a*, *Onecut1*) are important during pancreatic development but not expressed in mature islets and showed no substantial expression of either mRNA or lncRNA. The lncRNA expressed from the opposite strand of the *Pdx1* locus starts in the single intron of *Pdx1* although there is no sequence overlap between the mature lncRNA and mRNA ruling out a direct interaction between the two transcripts. qRT-PCR in eight mouse tissues showed that expression of both *Pdx1* and *Pdx1-asRNA* were restricted to islets. Whereas overexpression of *Pdx1-asRNA* exerted no significant effect on *Pdx1* activity as assessed by luciferase assay in MIN6 cells (overexpression vs empty vector control:  $0.111 \pm 0.002$  vs  $0.112 \pm 0.003$  RLU, mean  $\pm$  SEM  $n=3$   $p=0.728$ ), shRNAs against *Pdx1-asRNA* significantly decreased *Pdx1* activity ( $\alpha$ -*Pdx1-asRNA* shRNA vs  $\alpha$ -GFP shRNA control:  $0.066 \pm 0.002$  vs  $0.114 \pm 0.007$ , mean  $\pm$  SEM  $n=3$ ,  $p=0.002$ ).

**Conclusion:** We show here that lncRNAs are co-expressed from the loci of several key beta cell transcription factors. We demonstrate that the lncRNA expressed from the *Pdx1* locus in an islet-specific manner is required for the maintenance of normal *Pdx1* activity, and thus potentially for preserving beta cell mass and function.

### The regulatory role of miR-375 in the pancreatic beta cell secretome

S. Tattikota, M. Sury, T. Rathjen, C. Becker, M. Selbach, M. Poy;

Max Delbrück Centre for Molecular Medicine, Berlin, Germany.

**Background and aims:** The MicroRNA (*miRNA*) pathway has long been implicated in development and disease, including cellular stress. Recent studies have shown that an islet specific miRNA, *miR-375*, is crucial for the growth and function, notably insulin release, of pancreatic  $\beta$ -cells. The aim of the present study is to address the impact of *miR-375* on the pancreatic  $\beta$ -cell secretome from murine beta cell line MIN6, using the *Stable Isotope Labeling of Amino acids in Cell culture* (SILAC) based quantitative proteomic approach.

**Materials and methods:** MIN6 cells were labeled using SILAC method and *miR-375* and its targets were knocked-down systematically. 48hr later, secretion experiments were performed. The supernatant was concentrated and subjected to mass spectrometry to identify the respective secretome profiles.

**Results:** Using the SILAC based quantitative proteomic approach, we could identify over 600 proteins released, of which ~50 proteins that were regulated, in response to high glucose by the MIN6 beta cell line. Moreover, the secretome profiles following knockdown of *miR-375* and its target genes revealed differential regulation of many secreted proteins highlighting the complex regulatory role of this microRNA on the secretory machinery. Many of the proteins identified here, including the vitamin D binding protein, a gene previously correlated with the onset of Type I diabetes, have yet to be studied as a secreted factor from pancreas.

**Conclusion:** This study specifically addresses the role of *miR-375* in the systemic release of proteins from beta cells and provides insight into the future study of its direct targets and their role in exocytosis from this cell type.

## 214

**MicroRNA transfer as a new cell-to-cell communication mode between pancreatic beta cells**

C. Guay, V. Menoud, S. Gattesco, R. Regazzi;

Department of Cellular Biology and Morphology, University of Lausanne, Switzerland.

**Background:** MicroRNAs are important regulators of beta-cell functions. Recently, these small non-coding RNAs have been discovered to function not only inside the cells producing them, but also by their transfer in active form to recipient cells via microvesicles such as exosomes. This novel communication mode has been described in different cells of the immune system but remains poorly investigated in other biological systems. Two recent studies suggested that pancreatic beta-cell lines secrete microvesicles but their microRNA content was not explored. In the present study, we analyzed the microRNA content of microvesicles released by beta-cell lines and primary pancreatic islets and tested the biological relevance of beta-cell to beta-cell microRNA transfer.

**Material and methods:** MicroRNA-containing microvesicles released in the culture media of MIN6 or INS 832/13 beta-cell lines and of rat and human islets were isolated by ultracentrifugation. MIN6 cells were incubated in the presence of cytokines or palmitate to determine the impact of these pathophysiological conditions on microRNA release. Microvesicle preparations were first analyzed by microarray and by qRT-PCR to determine their microRNA content and were then used to study the impact of microRNA transfer on the function of recipient beta-cells.

**Results:** MicroRNAs were detected in the culture media of all beta-cell lines and primary islets tested. The microRNAs isolated from the culture media were fully protected against RNase treatment, suggesting that they are confined in microvesicle structures. Global profiling revealed that the microRNA content of microvesicles is not a mirror image of the cell content. Indeed, some microRNAs poorly expressed inside the cells were relatively abundant in microvesicles and vice-versa, indicating a preferential release of a subset of microRNAs. Moreover, incubation of MIN6 cells in the presence of cytokines or palmitate changed the level of several microRNAs released in the medium. We next investigated the dynamics of microRNA secretion and their transfer to recipient cells. Overexpression of miR-142-3p in MIN6 cells, a microRNA present at low level in beta-cells, resulted in a time-dependent release of this non-coding RNA in the culture media and its transfer into recipient MIN6 cells. Interestingly, incubation of untreated MIN6 cells in the presence of microRNA-containing microvesicles isolated from the culture media of MIN6 cells treated with cytokines led to an increase in cell death and a decrease in cell proliferation of recipient cells. In contrast, the microvesicles purified from the medium of untreated MIN6 cells did not affect the function of recipient cells.

**Conclusion:** Taken together, our results suggest that beta-cells are able to release microRNAs that can be transferred to neighboring beta-cells. Our observations indicate that a subset of microRNAs is preferentially selected for secretion. Exposure of donor cells to pathophysiological conditions associated with diabetes, such as treatment with cytokines or elevated fatty acid concentrations, modifies the release of microRNAs and affects the survival of recipient cells. More experiments will be needed to determine the precise contribution microRNA transfer to beta-cell dysfunction associated with diabetes. However, our results support the concept that microRNA transfer constitutes a novel cell-to-cell communication mechanism.

**MicroRNA target sites as genetic tools to enhance promoter-reporter constructs for the purification of pancreatic progenitor cells from differentiated embryonic stem cells**

U. Diekmann, S. Lenzen, O. Naujok;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

**Background and aims:** Insulin-producing surrogate cells generated by in vitro differentiation from pluripotent cell sources (PSCs) such as ESCs or iPSCs hold great promises to overcome the limitations of transplantation therapies for T1DM. Differentiation of PSCs produces heterogeneous cell populations which must be further purified from unwanted cells and cells that resisted differentiation. In this study the specificity of tissue-specific promoter reporter constructs was increased utilizing the embryonic microRNA (miRNA) expression. This allowed the purification of pancreatic progenitors (PP) by fluorescence activated cell sorting (FACS).

**Materials and methods:** MiRNA expression in the mouse ESC lines ES-CCE and ES-D3 was analyzed by qPCR during the differentiation towards pancreatic endoderm. A lentiviral vector system that contained the tissue-specific Pdx1 promoter controlled the expression of the fluorescent reporter GFP2. This genetic cassette was further modified by insertion of a miRNA target site for the miRNA mir-294 (mirT294). Both cell lines were stably transduced and clones were clonally expanded. Subsequently the clones were subjected to differentiation with the small molecules IDE1 for 6 days and with ILV and FGF10 for the next 4 days. The cells were then analysed by flow cytometry and FACS-sorted cells were characterized by IF and qPCR. **Results:** The Pdx1 tissue-specific promoter construct showed slight background fluorescence after lentiviral transduction and clonal expansion. FACS-sorted clones at day 10 or 15 showed a 5.3-fold or 8.8-fold increased Pdx1 expression in the GFP+ population, respectively, compared to the GFP-cells. The embryonic transcription factor Oct3/4 was 26.9-fold (d10) or 16.3-fold (d15) increased in GFP+ cells. This indicates that the sorted population consists of PPs mixed with partially or fully undifferentiated cells. To reduce the background fluorescence in ESCs the miRNAs mir-294, -302a and -302d were assessed during the differentiation process and normalized to snoRNA-202. Mir-294 expression decreased gradually upon differentiation (d0  $1.70 \pm 0.18$ ; d10  $0.06 \pm 0.01$ ). In ESCs mir-302a and -302d expression was not detectable, peaked at day 6 and disappeared afterwards nearly completely (mir-302a d6  $4.43 \pm 0.65$ ; d10  $0.08 \pm 0.02$ ). The mirT294 was cloned into the lentiviral vector which decreased the basal GFP2 expression specifically in undifferentiated ESCs. This could be shown for the strong constitutive CMV- and for the Pdx1-promoter constructs. Upon differentiation of CMV clones the fluorescence became detectable again. Moreover, sorted cells with the CEmPdx1-promoter GFP2 mirT294 construct (containing a CMV enhancer element) showed an increased Pdx1 expression in the GFP+ population compared to the GFP- cells. The expression of Oct3/4 was highly decreased in GFP+ cells compared to the GFP- population.

**Conclusion:** Integration of the mirT294 site into the lentiviral vector reduced the artificial background fluorescence in ESCs and permitted the purification of PP cells. The mir-302 cluster is apparently important for the mesendodermal differentiation in the mouse system whereas in human ESCs this cluster is also essential for pluripotency. In summary, this study presents a promising technique to specifically knock-down the expression of a gene of interest eg. during developmental processes utilizing the cellular miRNA expression in mirT's.

**Modifications of microRNAs expression affect beta cell function and survival before and after type 2 diabetes instauration**V. Nesca<sup>1</sup>, C. Guay<sup>1</sup>, C. Jacovetti<sup>1</sup>, V. Menoud<sup>1</sup>, R. Laybutt<sup>2</sup>, M. Prentki<sup>3</sup>, R. Regazzi<sup>1</sup>;<sup>1</sup>Department of Cell Biology and Morphology, Université de Lausanne, Switzerland, <sup>2</sup>Garvan Institute of Medical Research, St. Vincent's Hospital, Sydney, Australia, <sup>3</sup>Montreal Diabetes Research Center, University of Montreal, Canada.

**Background and aims:** Type 2 diabetes occurs when pancreatic beta-cells are unable to sustain insulin demand of the organism due to a decline in beta-cell function and an increase in beta-cell death. The mechanisms underlying dysfunction of beta-cells are complex and only partially characterized, since both genetic susceptibility and environmental factors are involved. In the present study, we investigated if a deregulation in the level of microRNAs, a class of non-coding RNAs known to be potent regulators of gene expression, could contribute to beta-cell dysfunction and death during the development of type 2 diabetes.

**Materials and methods:** MicroRNA expressions were analyzed in pancreatic islets of two models of type 2 diabetes, the db/db mice and the diet-induced obesity (DIO) mice, using microarray profiling. Functional effects resulting from expression changes were investigated in pancreatic beta-cell lines and in dispersed primary rat islet cells.

**Results:** We identified more than 60 microRNAs that are differently expressed in islets from db/db mice and/or from DIO mice. The most important changes were observed for miR-132, miR-199a-3p and miR-199a-5p which were up-regulated and miR-184, miR-203, miR-210 and miR-383, which were down-regulated in the islets of diabetic mice. The level of some of these microRNAs was already affected in islets of young pre-diabetic db/db mice, suggesting a progressive alteration during diabetes development. To investigate the role of these microRNAs in the regulation of beta-cell func-

tions and survival, we used oligonucleotide mimics or anti-miRs to up- or down-regulate, respectively, their level in MIN6B1 and in dispersed primary rat islet cells. Overexpression of miR-132 had a beneficial effect on beta-cells since it protected them from cytokine- and palmitate-induced cell apoptosis, promoted proliferation and glucose-induced insulin secretion. Down-regulation of miR-184 also increased proliferation, but did not improve beta-cell survival and insulin secretion. On the opposite, overexpression of miR-199a-3p or down-regulation of miR-203, miR-210 or miR-383 were detrimental to beta-cells since they induced apoptosis.

**Conclusion:** We observed changes in microRNAs expression in islets from type 2 diabetic animal models. Interestingly, some of the changes were already present before the development of the disease and resulted in improved beta-cell survival, proliferation and insulin secretion, suggesting that they may contribute to compensatory expansion of the functional beta-cell mass. In contrast, most of the changes observed in the islets of diabetic animals have detrimental impacts on beta-cells and are likely to contribute to beta-cell failure.

## OP 37 Metformin actions and benefits

217

**Effect of acute and short-term metformin treatment on 5'AMP-activated protein kinase regulation at rest and during exercise in human skeletal muscle and adipose tissue**

**J.M. Kristensen**<sup>1,2</sup>, C. Lillelund<sup>1</sup>, R. Kjøbsted<sup>1</sup>, J. Birk<sup>1</sup>, L. Nybo<sup>3</sup>, K. Mellberg<sup>4</sup>, A. Balendran<sup>4</sup>, E. Richter<sup>1</sup>, J. Wojtaszewski<sup>1</sup>

<sup>1</sup>Department of Exercise and Sport Sciences, Section of Human Physiology, Molecular Physiology Group, University of Copenhagen, Denmark,

<sup>2</sup>Department of Endocrinology, Section for Molecular Diabetes & Metabolism, Odense University Hospital and Institute of Clinical Research, University of Southern Denmark, Denmark, <sup>3</sup>Department of Exercise and Sport Sciences, Section of Human Physiology, Integrated Physiology Group, University of Copenhagen, Denmark, <sup>4</sup>AstraZeneca R&D, Mölndal, Sweden.

**Background and aims:** Metformin is a widely used drug for treatment of type II diabetic patients. Metformin works by suppressing hepatic glucose production, and also seems to improve insulin sensitivity by enhancing glucose uptake in skeletal muscle and adipose tissue. The molecular mechanism behind the effect of metformin is not fully elucidated, but activation of the 5'AMP-activated protein kinase (AMPK) has been observed in human skeletal muscle and adipose tissue after long-term treatment. Exercise is another potent stimulus for AMPK activation. We studied acute and short-term effects of metformin treatment on AMPK, in human skeletal muscle and adipose tissue at rest and during exercise.

**Materials and methods:** The study was conducted in a randomized blinded cross over design. Healthy moderately trained men were treated with metformin/placebo either once (3000 mg metformin) or for 4 days (increasing metformin dose from 1000-3000 mg daily) and conducted one bout of exercise after treatment. Blood samples and biopsies from the vastus lateralis muscle and from subcutaneous abdominal fat were obtained to study the effect of metformin treatment, acute exercise and the combination of these interventions. Differences between groups were considered statistically significant when  $P < 0.05$ .

**Results:** The metformin dosages elicited peak plasma and muscle metformin concentrations of 31  $\mu\text{M}$  and 11  $\mu\text{M}$ , respectively. The metformin treatment induced increased whole body stress indicated by significant increased plasma lactate (~60%), adrenaline (~25%), heart rate (~10%) and rate of perceived exertion during exercise. However, this was not reflected at the cellular level as the muscle metabolites lactate, creatine, phosphocreatine and glycogen were unaffected by metformin treatments both at rest and during exercise. Furthermore, neither of the treatments affected AMPK activity in resting skeletal muscle and adipose or potentiated exercise induced activation of AMPK in skeletal muscle.

**Conclusion:** We conclude that acute and short-term metformin treatment, despite eliciting high plasma metformin concentrations, does not affect AMPK at rest or during exercise in skeletal muscle and adipose tissue of healthy subjects.

**Metformin directly antagonizes the mitogenic effects of insulin, IGF-I and AspB10 (X10) insulin by regulating the cell cycle inhibitors cyclin G2 and p27kip**

**P. De Meyts**<sup>1</sup>, A.B. Jeppesen<sup>2</sup>, S. Winge<sup>1</sup>, A.M. Svendsen<sup>2</sup>, I.H. Lambert<sup>3</sup>, W. Sajid<sup>4</sup>

<sup>1</sup>Diabetes Biology and Hagedorn Research Institute, Novo Nordisk A/S, Gentofte, <sup>2</sup>Incretin Biology, Novo Nordisk A/S, Gentofte, <sup>3</sup>University of Copenhagen, <sup>4</sup>Diabetes Complications Biology, Novo Nordisk A/S, Gentofte, Denmark.

**Background and aims:** A debate is ongoing as to whether diabetes and some modalities of its treatment (e.g. with an insulin analogue) may increase the risk of cancer. In contrast, treatment with metformin has been proposed to have a beneficial effect on cancer risk. In previous work, we have shown that insulin, insulin-like growth factor-I (IGF-I) and a supermitogenic insulin analogue, X10, markedly downregulate the expression of mRNA and protein

for the cell cycle inhibitor cyclin G2 in several cell lines. Cyclin G2 is an atypical cyclin that, unlike other cyclins, blocks rather than stimulates cell cycle progression. Cyclin G2 has been found to be downregulated in a number of cancers. We showed that overexpression of cyclin G2 protected against the mitogenic effects of insulin, IGF-I and X10. We also found that insulin, IGF-I and X10 inhibit the protein level of another cell cycle inhibitor, p27<sup>Kip1</sup>. In the present work, we investigated whether metformin may counteract the mitogenic effects of insulin, IGF-I and X10 in wild-type L6 myoblasts (L6-WT, containing only IGF-I receptors (IGF-IR)) and L6 cells overexpressing the human insulin receptor (L6-hIR), and affect their downregulation of cyclin G2 and p27<sup>Kip1</sup>.

**Materials and methods:** Mitogenesis was measured by <sup>3</sup>H-thymidine incorporation into DNA. The mRNA levels of cyclin G2 and p27<sup>Kip1</sup> were measured by qRT-PCR, and the protein levels by Western blotting. The cells were starved of serum for 24 hours, and then exposed to insulin, IGF-I or X10 at various concentrations in the absence or presence of increasing concentrations of metformin for various periods of time.

**Results:** Insulin, IGF-I and X10 all markedly increased <sup>3</sup>H-thymidine incorporation into DNA in both L6-WT and L6 hIR cells. This effect was completely abolished at high concentrations of metformin, with an IC50 around 8 mM in L6-WT cells and 6.6 mM in L6-hIR cells. Metformin had no effect on the basal level of <sup>3</sup>H-thymidine incorporation into DNA. The antagonistic effect of metformin on mitogenesis induced by insulin, IGF-I and X10 was mimicked by the adenosine analogue 5-aminoimidazole-4-carboxamide ribonucleoside (AICAR), an agonist of AMP kinase. As we showed previously, insulin, IGF-I and X10 downregulated the mRNA level for cyclin G2 as well as the protein level in a time- and concentration-dependent fashion in both cell lines, the effect being much more pronounced in the L6-hIR cells. Metformin significantly decreased the downregulating effect of the three ligands on cyclin G2. The three ligands also downregulated the protein (but not mRNA) levels of p27<sup>Kip1</sup>, an effect that was also significantly reduced by metformin.

**Conclusion:** We demonstrate for the first time that metformin directly antagonizes the mitogenic effects of insulin, IGF-I and X10 through both the insulin and IGF-I receptors in cell culture. This effect is mimicked by AICAR, suggesting an AMP kinase-mediated effect. This antagonism appears to be mediated through the regulation of mRNA and protein levels of cyclin G2, and protein level of p27<sup>Kip1</sup>, two inhibitors of the cell cycle and tumour suppressors. How this relates to putative cancer-protecting effects of metformin deserves further study.

## 219

**Metformin enhances secretion of GLP-1 but not GIP and improves postprandial glucose excursion in Japanese patients with type 2 diabetes**  
H. Kuwata<sup>1</sup>, D. Yabe<sup>1</sup>, K. Sugawara<sup>1</sup>, R. Usui<sup>1</sup>, K. Sugizaki<sup>1</sup>, Y. Kitamoto<sup>1</sup>, S. Fujiwara<sup>1</sup>, K. Watanabe<sup>1</sup>, T. Hyo<sup>1</sup>, T. Murakami<sup>2</sup>, T. Yamaguchi<sup>2</sup>, S. Shimizu<sup>2</sup>, H. Eto<sup>2</sup>, T. Kurose<sup>1</sup>, Y. Seino<sup>1</sup>

<sup>1</sup>Division of Diabetes, Clinical Nutrition and Endocrinology, <sup>2</sup>Division of Clinical Laboratory Science, Kansai Electric Power Hospital, Osaka, Japan.

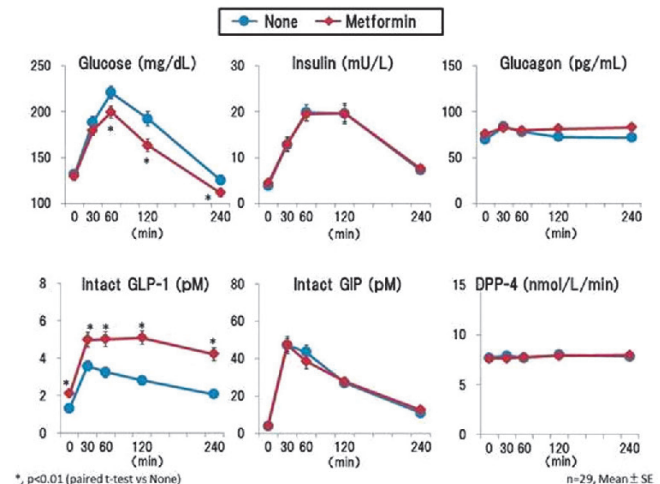

**Background and aims:** Recent studies have shown that metformin increases total and intact levels of glucagon-like protein-1 (GLP-1). However, little is known of the effects of metformin on secretion and metabolism of GLP-1 and glucose-dependent insulinotropic polypeptide (GIP) specifically in Asians. We evaluate here the effects of metformin on fasting and postprandial levels of GLP-1 and GIP in Japanese patients with type 2 diabetes.

**Materials and methods:** Twenty-nine untreated Japanese patients with type 2 diabetes [Age (year), 53.7±1.7; BMI (kg/m<sup>2</sup>), 27.6±1.1; HbA1c (NGSP%), 7.6±0.2] were subjected to meal tolerance test (MTT) using a Japanese standard breakfast (480 kcal; carbohydrate: protein: fat= 2.8:1:1) with or without administration of metformin (1,500mg/day). Blood samples were collected and total and intact GLP-1 and GIP levels were measured in addition to those of glucose, insulin, glucagon, and dipeptidyl peptidase-4 (DPP-4) activity.

**Results:** Metformin significantly lowered levels of plasma glucose at 60, 120 and 240 min after meal ingestion. The insulin/glucose ratio was elevated at 60, 120 and 240 min after meal ingestion, suggesting enhancement of postprandial insulin secretion relative to plasma glucose. Levels of fasting and postprandial GLP-1, both total and intact forms, were significantly elevated by metformin. In contrast, DPP-4 activity and total and intact GIP levels were unchanged throughout MTT.

**Conclusion:** In Japanese patients with type 2 diabetes, metformin improves the postprandial glucose excursion partly through elevation of intact GLP-1, but the drug does not affect GIP. Elevation of intact GLP-1 in these patients

is therefore likely due to enhanced insulin secretion rather than to inhibition of its degradation by DPP-4.

## 220

**Metformin improves intestinal L cell survival in vitro and in vivo**  
R. Jakubov<sup>1</sup>, P.L. Brubaker<sup>2</sup>, L.M. Lauffer<sup>3</sup>

<sup>1</sup>Internal Medicine II, Klinikum rechts der Isar, Munich, Germany,

<sup>2</sup>Physiology, University of Toronto, Canada, <sup>3</sup>Internal Medicine IV, Klinikum der Universität München, Munich, Germany.

**Background and aims:** Glucagon-like peptide-1 (GLP-1) is an insulinotropic hormone released from the intestinal L cell following stimulation by nutrients and other secretagogues. Hence, GLP-1 analogs and degradation inhibitors are now used in the therapy of type 2 diabetes. As recently reported, metformin, an AMP-protein kinase (AMPK) activator and a well established anti-diabetic drug, causes increased GLP-1 levels in vivo. Although the exact mechanism remains incompletely defined, direct stimulation of the intestinal L cells with metformin in vitro did not increase GLP-1 secretion. We hypothesized that the increased GLP-1 levels might be associated with enhanced L cell proliferation and decreased L cell apoptosis.

**Materials and methods:** To assess L cell survival, the mouse GLUTag L cell line was treated for 24 hr with metformin (150mM) or the AMPK-activator AICAR (1mM), followed by induction of apoptosis with cytokines or staurosporine, and immunoblot for cleaved Caspase-3, a marker of apoptosis. L cell proliferation following the same treatment (metformin or AICAR) was assessed by <sup>3</sup>H-thymidine incorporation. The effect of metformin in vitro was examined in rats treated neonatally with streptozotocin, a model of type 2 diabetes. The rats were maintained on a standard laboratory diet for 8 weeks, followed by 4 weeks treatment with metformin (300 mg/kg BW/day, supplied in water) with and without sitagliptin (2.8 g/kg BW, supplied in food) to further increase GLP-1 levels. The metformin and sitagliptin dose was adjusted daily according to daily measurements of drinking volume and bodyweight. The terminal 2 cm of the ileum was then extracted and cross-sections of the terminal ileum (200µm apart) were stained with a GLP-1 specific antibody, to visualize the L cells. For every rat at least 4 intestinal cross-sections were analyzed for absolute L cell counts.

**Results:** Incubation of GLUTag cells with metformin (150mM) or AICAR (1mM) decreased L-cell apoptosis by 33±4% (p<0.01) and 8±1% (p<0.01), respectively. While the same concentration of metformin did not affect proliferation of the GLUTag cells, AICAR increased proliferation by 74±7% compared to control (p<0.001). The rats treated with metformin showed a significant increase in the L cell counts (1.4±0.1 fold increase vs. control; n=4-6 rats; p<0.05). The addition of sitagliptin to metformin did not modulate the response to metformin (1.5±0.1 fold increase vs. control; n=4 rats; p<0.05).

**Conclusion:** Although metformin increases GLP-1 levels in patients, metformin does not directly stimulate GLP-1 release from intestinal L cell lines. As shown in our study, metformin improves survival of the L cells by decreasing apoptosis, potentially by modulating the AMPK signaling pathway. Additionally, metformin treatment in vivo increased the L cell counts, independent of sitagliptin, indicating a GLP-1-independent mechanism of the effect. Nonetheless, the mechanism of action of metformin to increase GLP-1 levels in humans in vivo needs further exploration. Taken together, these findings

provide further support for the effects of metformin to enhance GLP-1 levels, leading to improved control of type 2 diabetes in patients.

## OP 38 Hypoglycaemia

### 221

#### The effect of mild and severe hypoglycaemia and hypoglycaemia awareness on 12-year all-cause mortality in type 1 diabetes

A.-S. Sejling<sup>1</sup>, B. Thorsteinsson<sup>1,2</sup>, U. Pedersen-Bjergaard<sup>1</sup>;

<sup>1</sup>Department of cardiology, nephrology and endocrinology, Hillerød Hospital, <sup>2</sup>Faculty of Health Sciences, University of Copenhagen, Denmark.

**Background and aims:** Severe hypoglycaemia is reportedly associated with excess all-cause mortality and other adverse clinical outcomes in type 2 diabetes. It is presently unknown whether hypoglycaemia is a marker of underlying co-morbidities rather than a direct cause of death. We studied if an association exists between occurrence of episodes of mild (MH) and severe hypoglycaemia (SH) and long-term all-cause mortality in type 1 diabetes. Similar analyses were conducted for hypoglycaemia awareness since impaired awareness predisposes to both silent and severe hypoglycaemia.

**Materials and methods:** Twelve-year all-cause mortality was recorded in a cohort of 265 patients with type 1 diabetes (60% men; age 45±13 years (mean±SD) and duration of diabetes 21±12 years at entry). At baseline patients were asked about life-time number of SH and number of SH during the last two years, and their hypoglycaemia awareness class (44% aware, 44% impaired, and 12% unaware) was characterized. The patients were subsequently followed monthly for one year. SH was defined by third party assistance and was recorded and validated in telephone interviews within 24 hours in the prospective part of the study. MH was defined as episodes with symptoms familiar to the patient as hypoglycaemia and managed solely by the patient. These episodes were reported for the week preceding the return of the monthly questionnaires during the prospective part of the study.

**Results:** The 12-year all-cause mortality was 15% (n=39). SH and all-cause mortality were not associated, neither when retrospectively recorded (life-time number of episodes divided in 0-1 (46%), 2-5 (23%), 6-10 (10%) and >10 episodes (21%); p=0.09); the last two years before entry: 0-1 (69%), 2-5 (20%) and >5 episodes (11%); p=0.49), nor when prospectively recorded for one year after entry (0-1 (85%), 2-5 (10%) and > 5 episodes (5%); p=0.34). Occurrence of SH in the two last years before baseline (no=55%, yes=45%) and all-cause mortality were not associated (p=0.20). No associations between all-cause mortality and MH at baseline (0-1 (45%), 2 (29%) and >2 episodes per week (26%); p=0.22) or in the first year after entry (0-1 (37%), 2 (30%) and >2 episodes per week (33%); p=0.16) were observed. Finally, no differences existed in all-cause mortality between awareness classes (p=0.45). All-cause mortality was associated with long duration of diabetes (p=0.002), high age (p<0.001), and male gender (p=0.04), but not with HbA1c at entry (<7% (6%), 7-8.5% (46%) and >8.5% (48%); p=0.29).

**Conclusion:** We did not observe any association between long-term all-cause mortality and the occurrence of mild and severe hypoglycaemic episodes in type 1 diabetes. Likewise, mortality was not associated with class of hypoglycaemia awareness.

### 222

#### GAPP2™: Global survey finds three quarters of patients experience hypoglycaemia on insulin analogue causing dose irregularities and increased blood glucose monitoring

A. Tahrani<sup>1</sup>, A.H. Barnett<sup>2</sup>, M. Brod<sup>3</sup>, A. Rana<sup>4</sup>, M. Peyrot<sup>5</sup>;

<sup>1</sup>University of Birmingham, UK, <sup>2</sup>Heart of England NHS Foundation Trust and University of Birmingham, UK, <sup>3</sup>The Brod Group, Mill Valley, USA,

<sup>4</sup>Novo Nordisk, Copenhagen, Denmark, <sup>5</sup>Loyola University, Baltimore, USA.

**Background and aims:** Hypoglycaemic events are a major challenge in glycaemic control of type 2 diabetes (T2DM) with insulin and have a significant impact on morbidity, mortality and quality of life. A large global survey (GAPP2™) was conducted with T2DM patients taking insulin, and healthcare professionals (HCPs) (primary care, diabetes specialists and diabetes nurses/educators) to examine the frequency of self-treated hypoglycaemia (hypo) and assess and compare how patients and HCPs adjust insulin treatment in response to these events.

**Materials and methods:** A survey was performed in 6 countries in Europe, Asia and North America. 1653 HCPs managing T2DM and 3587 T2DM patients on insulin were recruited from online research panels with over 6.5 million members. The HCP and patient surveys included 50-70 questions examining dosing irregularities and hypos in T2DM managed with insulin.

**Results:** Data are presented from 3042 T2DM patients on insulin analogue (IA) and 1653 HCPs on their IA T2DM patients. 80% of patients reported having a hypo, with 76% of the most recent events diurnal and 24% nocturnal. 36% of patients had had a hypo in the last 30 days and the mean number of events reported by these patients was  $3.1 \pm 0.09$  per month ( $2.3 \pm 0.07$  diurnal and  $0.8 \pm 0.05$  nocturnal). 46% of patients had increased their blood glucose monitoring and more than 10% had altered their basal insulin (BI) regimen in response to a hypo. For the most recent hypo, patients reported missing (5%), reducing (7%) or mis-timing (3%) a mean of  $1.8 \pm 0.17$ ,  $4.2 \pm 2.08$ , and  $2.6 \pm 0.71$  BI doses. Patients reported that in order to reduce their risk of nocturnal hypos they had intentionally let their blood glucose go high (14%) or had not taken their insulin as prescribed (16%). Hypos had an impact on resource utilization as well as on disease management. 52% of HCPs reported being contacted at least once a month by IA patients after hypos and 82% reported that they consider hypo risk when choosing the type of insulin they initiate. 57% reported starting patients on a lower insulin dose than recommended due to risk of hypos. HCPs reported that on most occasions they advise patients who have a number of hypos to increase their blood glucose monitoring (35%), temporarily reduce (19%), reduce long-term (16%) or split (3%) their BI dose.

**Conclusion:** Hypos are extremely common for T2DM patients using IA and have a major impact on the way patients and HCPs manage diabetes. In response to hypos many patients increase blood glucose monitoring and some intentionally keep their blood glucose at a higher than appropriate level or adjust their BI dose to avoid these events. Many of the patient responses to hypos are inappropriate and suggest a need for further education or more HCP support.

#### Patient regimen modification in response to self-treated hypoglycaemia (hypo)

	Hypo patient response - ever	Hypo patient response - most recent event
Patients ever experiencing a mild hypo	2348	2348
Miss a basal dose	8%	5%
Mean number of doses missed		$1.8 \pm 0.17$
Basal dose taken >2 hrs earlier or >2 hrs later than prescribed	5%	3%
Mean number of doses mis-timed		$2.6 \pm 0.71$
Reduced a dose of basal	12%	7%
Mean number of doses reduced		$4.2 \pm 2.08$
Increased level of blood glucose monitoring	46%	40%
Mean length of time of increased monitoring (h)		$32.2 \pm 3.05$

### Effect of hypoglycaemia on ECG and EEG in type 1 diabetes

C.B. Juhl<sup>1,2</sup>, A. Larsen<sup>1</sup>, K. Højlund<sup>3</sup>, R. Madsen<sup>1</sup>;

<sup>1</sup>Hypo-Safe, Lyngby, <sup>2</sup>Department of Endocrinology, Sydvestjysk Sygehus, Esbjerg, <sup>3</sup>Department of Endocrinology, Odense University Hospital, Denmark.

**Background and aims:** Tight glycaemic control in type 1 diabetes may only be accomplished if severe hypoglycaemia can be prevented. Bio-sensor alarms based on the body's reactions to hypoglycaemia have previously been studied. Such alarms were based on different parameters such as skin conductance, electrocardiography (ECG) or electroencephalography (EEG). We have recently proposed an alarm based on continuous EEG monitoring and real-time data processing. In the present study we analysed three lead ECG and single channel EEG in type 1 diabetes patients exposed to insulin induced hypoglycaemia.

**Materials and methods:** From a group of fifteen patients exposed to insulin induced hypoglycaemia nine patients were included in the present analyses selected on the basis of the ECG and EEG quality. Glucose was gradually lowered by graded insulin infusion aiming a steady fall of glucose of 1 mmol/l/15 minutes and continued until the study subjects were obviously affected by

the low glucose. ECG and EEG was analysed post-hoc. Heart rate (HR), QTc interval (Bassett's method) and TpTec (time from top of T-wave to end of T-wave corrected for heart beat interval) were automatically calculated from the ECG recording. Three EEG features were extracted based on the spectral content of the signals in the delta band (1-4 Hz), the theta band (4-8 Hz), and the alpha band (8-13 Hz). Power estimates were computed continuously for 4 second epochs with 75% overlap between epochs. Both ECG and EEG features were thus calculated continuously allowing detection of the time of significant changes. The predefined variables were presence of ECG and EEG changes and time between detection of these changes and symptoms of severe hypoglycaemia.

#### Results:

Feature	True positive	False positive	Detection range (min)
<i>ECG features</i>			
QTc	6/9	1/9	0-26
TpTec	5/9	2/9	0-23
HR	5/9	3/9	2-16
<i>EEG features</i>			
EEG delta power	3/9	0/9	8-13
EEG theta power	8/9	0/9	4-24
EEG alpha power	4/9	0/9	7-20

The table shows detection rate and timing of hypoglycaemia associated ECG and EEG changes following graded insulin induced hypoglycaemia (N=9)

**Conclusion:** Severe hypoglycaemia is preceded by changes in both ECG and EEG features in the majority of the cases. EEG features appeared before severe hypoglycaemia in all cases and EEG theta power may be superior with respect to timing, sensitivity and specificity of severe hypoglycaemia detection. A multi-parameter algorithm which combines data from different biosensors might be considered.

Clinical Trial Registration Number: NCT00810420

## 224

### Liver glycogen loading augments the counterregulatory response to hypoglycaemia

J.J. Winnick<sup>1</sup>, G. Kraft<sup>1</sup>, W. Snead<sup>2</sup>, B. Farmer<sup>1</sup>, A.D. Cherrington<sup>1</sup>;

<sup>1</sup>Molecular Physiology & Biophysics, <sup>2</sup>Medicine, Vanderbilt University, Nashville, USA.

**Background and aims:** Latrogenic hypoglycemia is a persistent barrier to the safe, effective treatment of insulin-requiring people with type 1 and type 2 diabetes. During hypoglycemia, glucagon, epinephrine and cortisol are the primary counterregulatory hormones secreted into the blood and act to increase hepatic glucose output and reduce muscle glucose utilization, thereby restoring blood glucose homeostasis. The most readily available hepatic substrate to combat hypoglycemia is glycogen. Therefore, the purpose of this study was to determine whether hepatic glycogen content influences the response to a hypoglycemic challenge.

**Materials and methods:** During the first 4h of each study dogs received somatostatin and basal amounts of intraportal insulin and glucagon. Arterial blood glucose was doubled by glucose infusion into a peripheral vein and either saline (SAL; n=10) or fructose (FRU; 5.5  $\mu$ mol/kg/min; n=6) was infused into the hepatic portal vein, with the latter significantly stimulating hepatic glucose uptake and glycogen deposition as we have previously described. This glycogen loading period was followed by 2h of continued hyperglycemic/normoinsulinemia and the intraportal infusion of SAL or FRU was discontinued. During the final 2h period, hypoglycemia was induced in all animals using a 16x basal intraportal infusion of insulin. Animals from SAL were divided into two groups; one in which the endogenous counterregulatory hormone responses were allowed (SAL-ENDO; n=6) and a second group in which counterregulatory hormone responses were matched (SAL-MATCH; n=4) to those of FRU. Liver glycogen content at the outset of the hypoglycemic challenge was ~54 mg/g in SAL and ~82 mg/g in FRU.

**Results:** During the final hour of the 2h hypoglycemia period, arterial plasma glucose levels averaged  $2.6 \pm 0.1$  mmol in all three groups and the hepatic sinusoidal insulin levels were also similar ( $2514 \pm 102$ ,  $2340 \pm 186$  and  $2802 \pm 342$  pmol/l in SAL-ENDO, FRU and SAL-MATCH, respectively). In the glycogen loaded liver, net hepatic glucose output was greater during hypoglycemia ( $28 \pm 3$  and  $9 \pm 1$   $\mu$ mol/kg/min in FRU and SAL-ENDO, respectively;  $p < 0.001$ )

as were sinusoidal glucagon ( $108 \pm 25$  and  $65 \pm 7$  ng/l, respectively;  $p=0.06$ ) and arterial epinephrine ( $1791 \pm 356$  and  $955 \pm 225$  ng/l, respectively;  $p<0.05$ ) levels. When the glucagon ( $133 \pm 14$  ng/l) and epinephrine ( $1905 \pm 419$  ng/l) levels were matched in SAL-MATCH to those of FRU, net hepatic glucose output increased to a level ( $25 \pm 3$   $\mu\text{mol/kg/min}$ ) similar to that seen in FRU. Cortisol levels rose significantly in all groups, but did not differ among them.

**Conclusion:** Loading the liver with glycogen increases hepatic glucose output in response to hypoglycemia. Furthermore, this increase is mediated by an increase in the secretion of the counterregulatory hormones glucagon and epinephrine, suggesting that the brain may receive sensory feedback from the liver regarding the glucose stores that are available for mobilization. Thus, therapies that normalize liver glycogen content may be beneficial in preventing iatrogenic hypoglycemia in insulin-requiring humans with diabetes.

## OP 39 Diabetes education and its clinical impact

225

### Does duration of type 1 diabetes affect the outcomes of structured education?

J. Elliott<sup>1</sup>, S.R. Heller<sup>1</sup>, H.E. Hopkinson<sup>2</sup>, P. Mansell<sup>3</sup>;

<sup>1</sup>Department of Human Metabolism, University of Sheffield, <sup>2</sup>Department of Diabetes and Endocrinology, Victoria Infirmary, Glasgow, <sup>3</sup>Department of Diabetes and Endocrinology, University of Nottingham, UK.

**Background and aims:** One belief held by some physicians is that structured education in patients with Type 1 diabetes (T1DM) is best delivered within a few years of diagnosis, before inappropriate self-management strategies become ingrained. In this study we examined whether the duration of diabetes does influence the effectiveness of a structured education course in patients with T1DM, both in terms of biomedical and psychosocial parameters.

**Materials and methods:** The study was undertaken using the Dose Adjustment For Normal Eating (DAFNE) research database, which recruits patients undertaking DAFNE training as part of their normal clinical care, from 10 English secondary care diabetes centres. Ethics approval for this research database was approved by the Trent Research Ethics Committee, Rec No. 08/H0405/48. The first 479 patients with one year follow-up data were analysed (52% female, baseline mean $\pm$ SD: age  $41.2 \pm 13.9$  years, duration of diabetes  $17.3 \pm 15.0$  years). Biomedical and psychosocial questionnaire data were collected prior to, and 12 months after patients completed DAFNE education. Statistical significance was determined using paired Student's t-tests for continuous data and Chi-squared tests for categorical data, where a p value of  $<0.05$  was considered to be statistically significant. Correlations were examined utilising linear regression analyses.

**Results:** At 1 year follow-up HbA1c had decreased from  $8.7 \pm 1.5\%$  ( $72 \pm 17$  mmol/l) to  $8.5 \pm 1.5\%$  ( $70 \pm 17$  mmol/l) ( $p=0.002$ ). In those 381 patients with a baseline HbA1c of  $>7.5\%$  the decrease was  $9.2 \pm 1.3\%$  ( $77 \pm 14$  mmol/l) to  $8.9 \pm 1.5\%$  ( $73 \pm 16$  mmol/l) ( $p<0.001$ ). The number of episodes of severe hypoglycaemia in the preceding 12 months was greatly reduced from 393 to 99 ( $p<0.001$ ), and the number of patients experiencing one or more episodes had decreased from 101 to 42 ( $p<0.001$ ). Similar reductions were seen with diabetic ketoacidosis, the number of episodes decreased from 63 to 19 ( $p<0.001$ ) and the number of patients experiencing these episodes had decreased from 45 to 12 ( $p<0.001$ ). Quality of life improved as evaluated by the Problem Areas in Diabetes questionnaire (a measure of diabetes distress)  $29.1 \pm 20.2$  to  $21.2 \pm 17.6$  ( $p<0.001$ ), and Euro Qol-5D state of health  $71.3 \pm 17.6$  to  $74.5 \pm 18.2$  ( $p=0.001$ ). The presence of anxiety and/or depression was assessed using the Hospital Anxiety and Depression questionnaire. The number of patients with a probable anxiety or depression disorder decreased from 64 to 41 ( $p<0.001$ ) and from 27 to 21 ( $p<0.001$ ) respectively, furthermore the mean anxiety and depression scores decreased from  $4.8 \pm 4.6$  to  $4.2 \pm 4.4$  ( $p<0.001$ ) and  $3.0 \pm 3.6$  to  $2.6 \pm 2.5$  ( $p<0.001$ ) respectively. There was no correlation between the changes in any of the above biomedical or psychosocial measures following DAFNE education, and the duration of diabetes ( $R^2 \leq 0.01$ ).

**Conclusion:** Whilst improvement in HbA1c was modest in this cohort, this study shows that structured education for patients with Type 1 diabetes is equally effective irrespective of the duration of diabetes. The biomedical and psychosocial benefits of DAFNE skills training are independent of the duration of diabetes. Therefore a long duration of diabetes should not be a barrier to patient participation.

### Effect of a 5 days intervention programme for people with type 1 diabetes and severe hypoglycaemia

M. Glindorf, M. Wittrup;

Steno Patient Care Center, Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** The risk of developing late diabetic complications in type 1 diabetes is reduced by tight glycaemic control, but tight glycaemic control increases the frequency of hypoglycaemia. With increasing duration of diabetes severe hypoglycaemia (SH) defined as an episode requiring assistance from another person, becomes a significant problem, as many patients experience unawareness, and this gives rise to much concern. Since 1999 the

Clinic has conducted a 5 days inpatient Hypo-course for patients with type 1 diabetes prone to severe and frequent hypoglycaemia. An evaluation is now made to investigate if the patients experiences new acting competences to prevent and to handle SH. The aim of the course is to avoid or decrease the number of SH without increasing HbA1c, that patients regain awareness, decrease anxiety and improve behaviour in relation to prevent SH. Here we report results in relation to the last 24 participants.

**Materials and methods:** 15 Hypo-courses, each course includes 8 participants, with a total of 124 participants. The course is a 5 day inpatient course run by a multidisciplinary team, where communication in a narrative approach is fundamental and the philosophy is empowerment. The course contains knowledge in a daily life context about the relation between insulin, injection technique, monitoring blood glucose, awareness training, food and physical activity, alcohol, hypoglycaemia and unawareness. A daily activity-programme includes physical activity and exchange of experience between attendants who are also encouraged to experimental activities. A session with cohabitants includes sharing of feelings, concerns and involvement living with a person with SH. The present evaluation is based on both retrospective and prospective results and analysed in a mixed method design, with both quantitative and qualitative data. This presentation focuses on the result from the last three courses. 24 participants have answered 3 questionnaires: PAID, The HFS, WHO-5 before the course and 6 month later, and 1 questionnaire at the end of the course asking participants if they have got useful knowledge. We also measured HbA1c, self reported SH and change in awareness.

**Results:** 24 patients aged  $49.0 \pm 20$  years, 41.6 % female, A1C  $65.54 \pm 22.46$  mmol/mol, disease duration  $26.7 \pm 19$  years, microvascular complication 50 %, multiple complication 4.1 %, 91.6% with multiple insulin analog injections. At baseline the incidence of SH the last 2 years are > 21 (20.8 %) 11–20 (16.6 %) 6–10 (4.1 %) 1–5 (54.1 %). After 6 month average HbA1c was unchanged, patients improved hypoglycaemia awareness and 3 regained awareness, 91.6 % had no new SH. At the end of the course 91.6 % understand on an individual level how they can prevent SH based knowledge gained at the course. The HFS score improved significant ( $P = 0.004$ ), PAID score improved significant ( $P = 0.001$ ), WHO-5 no significant changes ( $P = 0.167$ ).

**Conclusion:** SH is a major problem for some patients with type-1 diabetes. The present Hypo-course concept based on empowerment and a narrative approach improves behaviour in relation to avoid SH without increasing HbA1c and results in a substantial decrease in the number of new episodes of SH, it decreases anxiety, improves behaviour in relation to avoid SH, and some patients regains or improves awareness.

### The maximum exercise is safe for the well-educated patients with type 1 diabetes

P. Niedzwiecki, A. Gawrecki, D. Naskret, A. Duda-Sobczak, S. Karbowska, B. Wierusz-Wysocka, D. Zozulinska-Ziolkiewicz, Department of Internal Medicine and Diabetology, Poznan University of Medical Sciences, Poland.

**Background and aims:** According to the Diabetes Poland recommendations intense, short exercise (> 90% VO<sub>2</sub>max) can lead to hyperglycemia and metabolic acidosis. Therefore aerobic exercise is recommended in patients with type 1 diabetes. The aim of the study was to assess the risk of decompensation of type 1 diabetes during maximal exercise.

**Materials and methods:** 10 well educated men, treated with personal insulin pump, aged  $23.0 \pm 5.6$  years, type 1 diabetes duration:  $11.1 \pm 3.7$  years, HbA1c  $7.0 \pm 0.2$  % (53 mmol/mol) were involved. Patients begun the exercise on a treadmill in 90th minute after ingestion of a standardized meal containing 90g of carbohydrates. Physical exercise of progressively increasing intensity was continued until the subjective sensation of fatigue assessed in 10 point Borg scale. The concentrations of lactic acid in serum and ketone bodies in the capillary blood were assessed before exercise, immediately after its completion, and after 6 hours. Glycaemia was measured using glucose meter and continuous glucose monitoring system (CGMS) before, during exercise and for 6 hours after its completion. Exercise test was performed twice during two different days.

**Results:** Serum concentration of lactic acid was: before exercise:  $1.57 \pm 0.39$  mmol/l, immediately after exercise:  $5.98 \pm 3.8$  mmol/l ( $p < 0.0001$ ; immediately after exercise vs before) and 6 hours after exercise:  $0.97 \pm 0.46$  mmol/l ( $p < 0.0005$ ; 6 hours after exercise vs before). No increase in ketone bodies concentration > 0.5 mmol/l was observed during the study. The distance achieved during the exercise was:  $3994 \pm 1593$  meters. Exercise time was:  $28.3 \pm 8.1$

minutes. Glycaemia measured on glucose meter before ingestion of standardized meal was:  $8.6 \pm 2.4$  mmol/l, before exercise (BE) was:  $10.9 \pm 2.0$  mmol/l, at the end of exercise (EE):  $7.4 \pm 2.5$  mmol/l ( $p < 0.0001$ ; BE vs EE), at 6 hour of observation(AE):  $10.5 \pm 3.7$  mmol/l ( $p = 0.62$ ; BE vs AE). Average glycaemia measured by CGMS before exercise (BE) was:  $9.8 \pm 2.2$  mmol/l, during exercise (DE):  $10.9 \pm 3.0$  mmol/l ( $p = 0.05$ ; BE vs DE), during 6 hours of observation (AE):  $9.9 \pm 2.6$  mmol/l ( $p = 0.77$ ; BE vs AE). There were no episodes of hypoglycaemia.

**Conclusion:** In the studied group the maximal exercise did not cause decompensation of type 1 diabetes.

## 228

### Health-related quality of life associated with daytime and nocturnal hypoglycaemic events: a time trade-off survey

J. Gungaard<sup>1</sup>, S.B. Harris<sup>2</sup>, M. Evans<sup>3</sup>, K. Khunti<sup>4</sup>, M. Mamdani<sup>5</sup>, C.B. Galbo-Jørgensen<sup>6</sup>, M. Bøgelund<sup>6</sup>,

<sup>1</sup>Novo Nordisk A/S, Søborg, Denmark, <sup>2</sup>Centre for Studies in Family Medicine, University of Western Ontario, London, Canada, <sup>3</sup>Llandough Hospital, Cardiff, UK, <sup>4</sup>University of Leicester, UK, <sup>5</sup>Department of Health Policy, Management, and Evaluation (Faculty of Medicine) and Leslie Dan Faculty, University of Toronto, Canada, <sup>6</sup>Incentive Partners, Holte, Denmark.

**Background and aims:** Hypoglycaemic events (hypos) can affect health-related quality of life (HRQoL) via acute symptoms, altered behavior and fear of future hypos. Nocturnal hypos, in particular, are unpredictable and difficult to avoid, and may affect HRQoL more than daytime hypos. We examined if HRQoL differs between daytime and nocturnal, severe and non-severe hypos, using time trade-off (TTO) methods.

**Materials and methods:** HRQoL was quantified via an online TTO survey with 10,087 respondents from the general population in the UK, USA, Canada, Germany and Sweden. Hypos were defined based on symptoms, and were classified as severe if third-party assistance was required. Descriptions of hypo health states were derived from a survey of 247 UK patients with diabetes. HRQoL was measured on a utility scale with 0 equating to dead and 1 perfect health. Respondents traded-off length of life for improving health states and evaluated health states of well-controlled diabetes and diabetes with non-severe/severe and daytime/nocturnal hypos.

**Results:** Table 1 shows the results. Non-severe nocturnal hypos were associated with 0.0026 (95% CI 0.0016; 0.0034) higher disutility compared with non-severe daytime hypos (equivalent to a 63.4% increase in negative impact); severe nocturnal hypos were associated with 0.0057 (95% CI -0.0001; 0.0114) higher disutility compared with severe daytime hypos (not statistically significant).

**Conclusion:** The study estimates the disutility associated with diabetes, uniquely illustrating the detrimental effect of hypos on HRQoL and in particular demonstrating the adverse effect of nocturnal hypos on HRQoL compared with daytime hypos. Indeed, the impact of nocturnal hypos have, in the past, been underappreciated by both clinicians and patients. These results highlight the clinical imperative of avoiding hypos, especially nocturnal hypos, to improve HRQoL at the patient level.

Table 1. Utility estimates from the time trade-off survey

Type of hypoglycaemia	n	Average utility	Standard error	95% CI lower	95% CI upper
Diabetes with no hypoglycaemia	7642	0.8440	0.0022	0.8395	0.8484
Non-severe daytime event	7435	-0.0041	0.0003	-0.0035	-0.0047
Non-severe nocturnal event	7347	-0.0067	0.0004	-0.0059	-0.0074
Severe daytime event	3603	-0.0565	0.0021	-0.0527	-0.0606
Severe nocturnal event	3647	-0.0622	0.0021	-0.0582	-0.0663

## OP 40 Glucose fluctuations and cardiac complications

229

### Prognostic value of admission glycaemic excursions in elderly patients with acute coronary syndrome

S. Mi<sup>1</sup>, G. Su<sup>1</sup>, Z. Li<sup>2</sup>, H. Yang<sup>1</sup>, H. Zheng<sup>1</sup>, H. Tao<sup>3</sup>, Y. Zhou<sup>1</sup>, L. Tian<sup>1</sup>;  
<sup>1</sup>Beijing An Zhen Hospital of Capital Medical University, <sup>2</sup>Emergency center, Beijing An Zhen Hospital of Capital Medical University, <sup>3</sup>Endocrinology department, Beijing An Zhen Hospital of Capital Medical University, China.

**Background and aims:** Acute phase hyperglycaemia has been associated with increased mortality in patients with acute coronary syndrome (ACS). However, the predictive value of admission glycaemic excursions for adverse outcome in elderly ACS patients is unknown. This study is to investigate the prognostic value of admission glycaemic variability for one-year major adverse cardiac event (MACE) in elderly patients with ACS.

**Materials and methods:** 186 elderly ACS patients' clinical data were collected and the GRACE risk score were calculated as admission. The fluctuations of glucose levels in patients were measured by a continuous glucose monitoring system (CGMS) for 72 hours. The occurrence of MACE in patients was documented during one year follow-up. All participants were grouped into tertiles of mean amplitude of glycaemic excursions (MAGE), absolute means of daily differences (MODD) and postprandial glucose excursion (PPGE) to compare the baseline data, the level of GRACE risk score and the incidence of MACE among the subgroups. A multivariate Logistic stepwise regression model was made to explore the independent contribution to cardiovascular outcomes.

**Results:** In all patients, a higher MAGE, MODD or PPGE level was associated with advanced age, the higher levels of heart rats, admission blood glucose and hemoglobin A<sub>1c</sub>, the lower level of left ventricular ejection fraction value, and a higher GRACE risk score and higher incidence of MACE. The same results were also found in elderly ACS patients with and without diabetes history. Levels of MAGE (4.07±1.37 mmol/L vs. 2.77±1.37 mmol/L,  $p<0.001$ ), MODD (2.66±1.01mmol/L vs. 1.62±0.76mmol/L,  $p<0.001$ ) and PPGE (6.06±2.61 mmol/L vs. 3.47±2.13 mmol/L,  $p<0.001$ ) were significantly higher in patients with MACE than in patients without MACE. Multivariate analysis indicated that age, previous CAD history, high-sensitive C reactive protein, admission blood glucose, eGFR, MAGE and MODD were independent determinants for MACE. After adjusting for GRACE risk score, diabetes history, hypoglycemic therapy and other confounders, MAGE ( $p=0.003$ ) and MODD ( $p=0.052$ ) levels retained a significant independent association with occurrence of MACE.

**Conclusion:** The admission intraday and interday glycaemic variability may be associated with the outcome of elderly patients with ACS. Acute glycaemic excursions, as one of components of the dysglycaemia, should not be neglected in ACS patients.

### Glycaemic variability and ventricular cardiac arrhythmias in type 2 diabetic patients with chronic heart failure

I. Pochinka, L. Strongin, J. Struchkova;  
 The Nizhny Novgorod State Medical Academy, Russian Federation.

**Background and aims:** Prevalence of chronic heart failure in population with diabetes is wide. Ventricular arrhythmias seem one of the factors that determine the prognosis of heart failure. It has to be checked whether glycaemic variability has an influence on ventricular cardiac arrhythmias in type 2 diabetic patients with chronic heart failure.

**Materials and methods:** An observational study was performed. 80 type 2 diabetic patients with chronic heart failure were included. The severity of heart failure was estimated by a 6-minute walk test and by the echocardiography, 48 patients (60%) characterized by III and IV functional class of heart failure. The median of duration of diabetes was 11 years. 40 patients (50%) used oral hypoglycaemic agents, 36 (44%) - insulin as monotherapy or in combination with oral medication, 5 (6%) - on the diet. Follow-up was 6 months. The study protocol included a 3-fold daily Holter electrocardiogram monitoring: at the inclusion visit, at 3 months and 6 months. Patients kept diaries of self-control blood glucose levels and hypoglycaemic events. During the day of Holter monitoring glucose was studied before meals, 2 hours after main meals, at

bedtime and 3 am. Combined simultaneous monitoring (Holter + continuous glucose monitoring) was performed in 20 patients. We used the CGM system by Medtronic MiniMed (USA) and the "Myocard-Holter" (NIMP ESN Ltd, Russia). Ventricular arrhythmias 4-5 and E-D gradations by Myerburg R.J. (2001) were regarded as dangerous. The parameters of glycaemic variability were also examined.

**Results:** 7 patients died during the study. Dangerous ventricular arrhythmias were detected in 42 patients (51 %) in 3-fold Holter monitoring. Glucose less than 5 mmol/l during the day of Holter increased 4.8 times the risk of dangerous arrhythmias ( $p=0.03$ ; logistic regression). Mean Amplitude of Glycaemic Excursion (MAGE) was associated with dangerous ventricular arrhythmias. There is a direct correlation between the level of MAGE and the number of ventricular premature beats ( $r=0.54$ ;  $p=0.02$ , Spearman). MAGE in patients with arrhythmias was 5.3 mmol/l [4.9; 6.3], in cases without arrhythmias - 2.4 mmol/l [2.0; 3.0] ( $p=0.006$ , Mann-Whitney U-test). Prevalence of dangerous ventricular arrhythmias in cases with MAGE > 5 mmol/l was 43 %, in cases with MAGE < 5 mmol/l - only 8 % ( $p=0.02$ , Pearson Chi-square).

**Conclusion:** The high glycaemic variability (MAGE > 5.0 mmol/l) is associated with dangerous ventricular arrhythmias. The high glycaemic variability is a proarrhythmic factor in type 2 diabetic patients with heart failure.

231

### Glycaemic fluctuations and arrhythmias in type 2 diabetes with cardiovascular disease

M. Hanefeld<sup>1</sup>, A. Stahn<sup>1</sup>, E. Henkel<sup>1</sup>, M. Teige<sup>1</sup>, C. Koehler<sup>1</sup>, A. Thomas<sup>2</sup>;  
<sup>1</sup>Center for Clinical Studies, GWT-TUD GmbH, Germany, <sup>2</sup>Medtronic GmbH, Meerbusch, Germany.

**Background and aims:** Patients with type 2 diabetes and cardiovascular disease (CVD) may represent a high risk group for arrhythmias and sudden death in hypoglycemic episodes. Little is known on frequency of asymptomatic hypoglycemia and its relationship to arrhythmias. By parallel measurement of interstitial glucose (i. G.) concentrations with continuous glucose measurement system (CGMS) and long-term ECG recording (LT-ECG) we therefore analysed the following questions in a high risk cohort:

- 1 - Relationship between low i. G. concentration and frequency of arrhythmias
- 2 - Relationship between fluctuation and frequency of arrhythmias
- 3 - Critical arrhythmias and their determinants

**Materials and methods:** 23 patients with type 2 diabetes, HbA<sub>1c</sub> < 9 %, age 50 - 80 years, with proven CVD, treated with insulin and/ or sulfonylurea, were considered. CGMS with Medtronic MiniMed Gold™ system and ECG with Amedtec ECG pro\* were recorded in parallel for 5 days and we analysed the frequency of ventricular extrasystoles and salvos, supraventricular extrasystoles and measured cQT-time. Hypoglycemia by CGMS was defined as modest (3.1-3.9 mmol/L) or severe (<3.1 mmol/L). The patients noticed symptoms of hypoglycemia and arrhythmias in a predefined protocol.

**Results:** The patients recorded only few mild symptomatic hypoglycemia. However we observed a high frequency of silent hypoglycemic episodes by CGMS. No arrhythmias were reported by the patients although we observed serious ventricular arrhythmias like ventricular tachycardias by LT-ECG. Hypoglycemic episodes and arrhythmias were most frequent at night.

**Conclusion:** Patients with CVD on insulin or sulfonylurea treatment represent a high risk for silent hypoglycemia and arrhythmias. Avoidance of excessive glucose fluctuations in glucose lowering treatment might be of importance to protect patients with CVD from arrhythmias.

232

### A short-term improvement of blood glucose control increases aspirin sensitivity in aspirin-resistant type 2 diabetic men

I. Russo, C. Barale, M. Chirio, M. Secchi, M. Viretto, G. Doronzo, L. Mattiello, A. Pagliarino, F. Cavalot, M. Valle, G. Anfossi, M. Trovati;  
 Department of Clinical and Biological Sciences of the Turin University, Internal Medicine and Metabolic Disease Unit, San Luigi Gonzaga Hospital, Orbassano - Turin, Italy.

**Background and aims:** Aspirin is recommended to the majority of patients affected by type 2 diabetes mellitus (T2DM) although the aspirin-induced prevention of cardiovascular events is smaller in diabetes than in the general population. Determinants of the aspirin resistance and of its reversibility in T2DM, however, are poorly clarified. We aimed at verifying whether in T2DM

men a short-term improvement of blood glucose (BG) control influences aspirin resistance.

**Materials and methods:** T2DM men with HbA1c >7.5% (n=37, age: 61.6±1.2 years, known diabetes duration 12.8±1.1 years, BMI: 29.6±0.60 kg/m<sup>2</sup>, HbA1c: 8.9±0.14%), on 100 mg/day aspirin were submitted to a 3-month intervention aiming to reach the best possible BG control by implementation of hypoglycaemic therapy with a careful avoidance of hypoglycemia. No change in hypolipidemic or anti-hypertensive treatment was allowed. Before and after the intervention, platelet sensitivity to aspirin was evaluated by Platelet Function Analyzer-100 (PFA-100): the cut-off for aspirin sensitivity is a closure time >200 sec. Among many other parameters, we evaluated: blood pressure (BP), hemoglobin A1c (HbA1c), fasting and post-prandial BG, lipids, von Willebrand Factor (vWF), a determinant of PFA-100 response. Data are expressed as mean±SEM. To compare subjects within and between the two groups, two factor mix design ANOVA and Spearman's correlation analysis were used.

**Results:** At baseline, aspirin sensitive (n=27, 73%) and aspirin resistant (n=10, 27%) subjects did not significantly differ for age, known diabetes duration, BMI, systolic and diastolic BP, HbA1c, fasting and post-lunch BG, HDL-cholesterol, triglycerides, and vWF, whereas aspirin-resistant subjects presented higher levels of total cholesterol (185.3±8.9 vs 156.6±5.4 mg/dl, p<0.009), LDL-cholesterol (105.3±14.3 vs 70.6±8.7 mg/dl vs, p<0.05) and apo B100 (93.0±4.9 vs 77.2±3.0 mg/dl, p=0.009). BG variables decreased after the intervention in aspirin sensitive and in aspirin resistant patients: i) HbA1c, from 8.8%±0.2% to 7.6%±0.1% (p<0.0001) and from 9.2%±0.3% to 7.6±0.2% (p<0.0001), respectively; ii) fasting BG, from 177.8±7.2 to 153.4±5.6 mg/dl (p<0.002) and from 181.7±11.9 to 134.3±9.1 mg/dl (p<0.0001), respectively; iii) post-lunch BG, from 182.1±9.3 to 144.4±6.9 mg/dl (p<0.0001) and from 186.3±15.3 to 148.0±11.3 mg/dl (p<0.009), respectively. PFA-100 values did not change in patients already aspirin-sensitive at baseline, but significantly improved in the aspirin-resistant-ones, from 149.2±10.4 to 228.5±15.0 sec (p=0.0001). In aspirin-resistant subjects baseline values of PFA negatively correlated with HbA1c (rho=-0.835, p=0.003) and fasting BG (r=-0.806, p=0.05).

**Conclusion:** i) 27% of poorly controlled T2DM men are aspirin resistant; ii) aspirin resistant T2DM men are characterized by higher values of total and LDL-cholesterol and of apoB-100 vs the aspirin sensitive-ones; iii) in aspirin resistant T2DM men, platelet sensitivity to aspirin strongly correlates with the BG control, whose improvement is accompanied by a decrease of aspirin resistance. Thus, BG improvement plays a major role in the reversal of aspirin insensitivity in T2DM men.

## OP 41 Modifiers and markers for cancer in type 2 diabetes

233

**Short- and long-term survival in Scottish cancer patients with and without co-morbid type 2 diabetes (1997-2007)**

J.J. Walker, The Scottish Diabetes Research Network Epidemiology Group; Centre for Population Health Sciences, The University of Edinburgh, UK.

**Background and aims:** Cancer patients who have pre-existing diabetes at diagnosis are at greater risk of long-term all-cause mortality than those without diabetes. However, relatively few studies have examined how the influence of diabetes on survival varies for specific cancers throughout the time period after cancer is diagnosed. This study investigated short- and long-term survival in Scottish cancer patients with and without Type 2 diabetes (T2DM) for cancer of the breast, lung, prostate and colon/rectum.

**Materials and methods:** Data from a population-based national diabetes register and the Scottish Cancer Registry were used to investigate associations between co-morbid diabetes (at the time of cancer diagnosis) and all-cause survival in the intervals 0 to 1 year, >1 to 2 years, >2 to 5 years and over five years after diagnosis. People in Scotland diagnosed with any of the cancers of interest during 1997 to 2007 were followed up until the end of 2010. Cox regression models incorporating terms representing the interaction between time and presence of T2DM were fitted to estimate the hazard ratio (HR; T2DM vs. no diabetes) in each interval. Separate models were fitted for each combination of sex and cancer site. Estimates were adjusted for age at cancer diagnosis, socio-economic status (SES) and cancer stage at diagnosis (breast and colon/rectum only). All models were re-fitted with additional predictors representing broad categories of cancer treatment (surgery, radiotherapy, chemotherapy). Cumulative incidence functions were calculated and plotted to provide insight into the respective probabilities of death from the index cancer and from any other cause over the period studied.

**Results:** Numbers of patients without diabetes ranged from a minimum of 12,082 (female; cancer of the colon/rectum); the corresponding number with pre-existing T2DM was 948. During the intervals 0 to 1 year and >1 to 2 years post diagnosis, survival did not differ significantly by diabetes status for any cancer. In the interval >2 to 5 years, survival in the T2DM group was poorer in men with prostate cancer (HR 1.28; 95% confidence interval [CI] 1.15 to 1.41) and, marginally, in women with colorectal cancer (HR 1.18; 95% CI 1.01 to 1.38). Over the interval >5 years, significantly elevated risk in the T2DM group was observed for all sex/site combinations except women with lung cancer. Hazard ratios for men in this interval were lowest for prostate cancer (HR 1.33; 95% CI 1.16 to 1.52). For women, the least elevation of risk was for lung cancer (HR 1.31; 95% CI 0.84 to 2.03). Further adjustment for cancer treatment did not materially change the results. Examination of cumulative incidence functions indicates that the respective probabilities of death from the index cancer and from any other cause differ markedly across cancer sites.

**Conclusion:** This study indicates that the presence of co-morbid Type 2 diabetes at the point of cancer detection does not influence survival (in respect of death from any cause) during the first two years after cancer is diagnosed. Over a more extended period, the influence of co-morbid T2DM varies by sex and cancer site, with higher risk generally observed in those with diabetes over the interval beyond 5 years. This elevation of risk may reflect less aggressive cancer therapy received by patients with co-morbid diabetes, and the increased susceptibility of people with diabetes to death from causes other than cancer (e.g. heart disease).

**High proinsulin levels are independently associated with 20-year cancer mortality. The Hoorn study**

I. Walraven<sup>1,2</sup>, E. van 't Riet<sup>2</sup>, C.D.A. Stehouwer<sup>3</sup>, B.C. Polak<sup>1</sup>, G. Nijpels<sup>2</sup>, J.M. Dekker<sup>2</sup>;

<sup>1</sup>Ophthalmology, VU Medical Center, Amsterdam, <sup>2</sup>Epidemiology and Biostatistics, VU Medical Center, Amsterdam, <sup>3</sup>Internal Medicine, Maastricht University Medical Center, Netherlands.

**Aims:** High proinsulin levels are associated with all-cause and cardiovascular mortality. It is unclear whether they are associated with cancer mortality

as well. It is shown that proinsulin binds with and activates insulin receptor isoform A, which in turn has been found in cancer cells and mediates the growth effects of pro-insulin-like growth factor II. The aim of this study was to investigate the independent association of proinsulin levels with 20-year cancer mortality in a population-based study.

**Materials and methods:** The current study was performed within the Hoorn Study, a population-based cohort study of glucose tolerance status among Caucasians aged 50–75 years. Fasting proinsulin levels were measured by a double-antibody radioimmunoassay on two separate days. Participants were continuously followed to register mortality, causes of death were derived from medical records. Cox survival analyses were performed to assess the 20-year cancer mortality risk in relation to tertiles of proinsulin levels. All analyses were adjusted for age and sex, with additional adjustments for variables that changed the relationship more than 10%, i. e. glucose tolerance status (WHO 1999), waist circumference, HDL-cholesterol and hypertension. Furthermore, we tested for interaction of glucose tolerance status and sex with proinsulin tertiles.

**Results:** Fasting proinsulin levels were available in 511 participants (baseline mean age 60 years, 41% normal glucose tolerance, 35.7% impaired glucose tolerance and 23.3% diabetes mellitus type 2). Of those, 53 individuals died from cancer. Individuals who died from cancer were older and had significantly higher specific insulin and proinsulin levels at baseline. After adjustment for age and sex, the highest tertile of proinsulin ( $> 16.5$  pmol/L) was significantly associated with cancer mortality [hazard ratio (HR) 1.99 (95% CI 1.04 to 3.82)]. Additional adjustment for possible confounding and/or specific insulin did not substantially change the results [HR 2.16 (95% CI 1.05 to 4.44)] (figure 1). No interaction with glucose tolerance status or sex was observed.

**Conclusion:** In the current study, we showed that fasting proinsulin levels above 16.5 pmol/L as compared to fasting proinsulin levels below 9.4 pmol/L were significantly associated with increased rates of cancer mortality over a 20-year time span. This association was independent of glucose tolerance status, waist circumference, HDL-cholesterol, hypertension and specific insulin. These findings provide population-based evidence for the independent association of high proinsulin levels with cancer mortality.

**Figure 1.** Kaplan-Meier curves of the 20-year cancer mortality risk in relation to tertiles of fasting proinsulin

## 235

### Metformin reduces growth and progression of pancreatic tumours in obese diabetic mice through regulation of cancer stem cell-associated gene expression

V. Cifarelli, S.M. Dunlap, L.M. Lashinger, S.D. Hursting;  
Department of Nutritional Sciences, School of Human Ecology, The University of Texas at Austin, USA.

**Background and aims:** The risk of developing pancreatic cancer (PC) is increased during diabetes mellitus. Epidemiological studies demonstrate that glucose-lowering therapies might impact the risk for PC in type 2 diabetes (T2D) patients. Metformin, an extensively used drug for the treatment of T2D, has been shown to be positively associated with the decreased risk of

PC in T2D patients. However, the mechanism of metformin inhibition of initiation of PC remains unknown. The aim of this study was to investigate the direct effect of metformin on growth and progression of PC using a tumor cell transplant mouse model fed the Diet Induced Obesity (DIO) diet. We analyzed the direct effect of metformin on the pancreatic cancer stem cell (CSC) population and cells that have an epithelial-to-mesenchymal transition (EMT) phenotype. These cells are hypothesized to be the cause of tumor recurrence and metastasis. Since CSCs can expand as sphere-like cellular aggregates, we studied the effect of metformin on the formation of pancreatic tumor sphere formation and associated genetic markers of CSCs and EMT.

**Materials and methods:** Mouse pancreatic cancer cells Panc02 were cultured for 24–72h in presence or absence of metformin (0.5–5mM). CD24+CD44+CD133+ CSCs population was identified by Flow Cytometry. Oct-4 and Notch expression, such as markers required to maintained stem cell identity, was analyzed by qRT-PCR. For the tumor sphere formation assay, Panc02 were seeded in ultra low adherent 6-well plate, using a DMEM/F12 media supplemented with B-27 and N2 growth factors. Tumor spheres were collected by centrifugation and the expression of EMT markers was analyzed by qRT-PCR. C57BL/6 mice (n=50, male) were rendered diabetic by DIO diet (60%kcal from fat). After 15 weeks of diet, metformin (250 mg/kg) was administered in drinking water, whereas control mice received regular water for 4 weeks. Panc02 cells were then injected subcutaneously. Mice continued metformin treatment for the duration of the study and tumor growth was monitored for 4 weeks post-injection.

**Results:** Metformin reduced pancreatic CSCs expression in Panc02 by 25% compared to control after 24h treatment ( $43.6\pm2.9$  vs.  $60.8\pm0.9$  in control;  $p<0.01$ ). The expression of Oct-4 and Notch were also decreased by 60% ( $\pm0.108$ ) and 50% ( $\pm0.002$ ) respectively. EMT regulators, Snail and Zeb-1, were decreased ( $RQ=0.72\pm0.06$  and  $RQ=0.64\pm0.11$ ) after metformin treatment. Metformin inhibited the expression of Vimentin ( $RQ=0.68\pm0.15$ ), TGF- $\beta$  ( $RQ=0.62\pm0.06$ ) and Fibronectin ( $RQ=0.81\pm0.02$ ) (all  $p<0.05$  vs. control) after 24h treatment. Metformin reduced the number ( $11.1\pm3.37$ ;  $p<0.05$ ; vs.  $23.8\pm5.7$  in control) and the size ( $115\mu\text{m}\pm21.9$  vs.  $187\mu\text{m}\pm34.05$  in control;  $p=0.01$ ) of tumor spheres. In diabetic mice, metformin improved hyperglycemia, reduced body weight ( $42.5\text{g}$  control vs.  $40\text{g}$  treated mice) and pancreatic tumor growth, and modulated the expression of EMT markers.

**Conclusion:** Our results indicated that metformin directly affects pancreatic cancer growth and progression by reducing the CSC population and gene expression PC in obese diabetic mice. Metformin reduces pancreatic cancer stem cells expression and affects the growth and progression of pancreatic tumor in diabetic mice.

### The disturbances of non-specific immunity of type 2 diabetic patients with colon cancer

A. Czech<sup>1</sup>, P. Piatkiewicz<sup>1</sup>, T. Milek<sup>2</sup>, M. Kniotek<sup>3</sup>, M. Bernat-Karpinska<sup>1</sup>, M. Nowaczyk<sup>3</sup>, M. Bernas<sup>1</sup>;

<sup>1</sup>Chair and Department of Internal Diseases and Diabetology, <sup>2</sup>Chair and Department of General and Vascular Surgery, <sup>3</sup>Department of Clinical Immunology, Warsaw Medical University, Poland.

**Background and aims:** Peripheral blood NK cells represent the first line defense in the immune system. Glucose metabolism disorders may influence anticarcinogenic function of these cells. The earlier obtained results revealed significant impairment in activity of NK cells in Type 2 diabetes. The aim of this study was to evaluate the number and cytotoxic activity of NK cells obtained from Type 2 diabetic patients (T2D) with negative family history of cancer, Type 2 diabetic subjects with newly diagnosed untreated colon cancer (T2DCC), and subjects without Type 2 diabetes with newly diagnosed, untreated colon cancer (CC).

**Materials and methods:** Incubation tests were performed in 18 newly diagnosed T2D, naive to any hypoglycaemic drugs, 16 T2DCC cT1-4N0M0 (c-clinical diagnosis based on computer tomography, colonoscopy and histopathology) treated with diet only or oral antidiabetic agents and 16 normoglycemic CC cT1-4N0M0. The control group included 18 metabolically healthy subjects (HS) with negative family history of cancer, matched with age, BMI and waist circumference. Peripheral blood mononuclear cells (PBMC) were isolated by Ficoll gradient centrifugation. The K562 human erythroleukemia cell line was used as the standard target for human NK cytotoxicity assay. K562 were labelled with DIO(3,3-diocetadecyloxycarbocyanine perchlorate). Target and effector cells were added to reach effector/target ratios: 50:1, 12:1. Dead target cells were stained with PI (propidium iodide). After 4 hours of

incubation data was collected for analysis on the Becton-Dickinson FACS-calibur flow cytometer. The data was analyzed using Cell Quest software. The results were compared using Aspin-Welch test.

**Results:** The T2D in comparison to HS had an increased number ( $13,56 \pm 5,9\%$  vs  $9,50 \pm 4,8\%$ ,  $p < 0.05$ ) but decreased activity ( $3,3 \pm 2,5\%$  vs  $9,4 \pm 3,6\%$ ,  $p < 0.01$ ) of NK cells. The CC demonstrated substantially decreased activity ( $2,9 \pm 1,8\%$ ;  $p < 0.01$ ) but similar number ( $8,82 \pm 3,7\%$ ; ns-not statistically significant) of NK cells when compared to the HS. The T2DCC NK cells were characterized by very small cytotoxic activity ( $1,1 \pm 0,7\%$ ;  $p < 0.01$ ) and nearly 2-fold higher number ( $21,24 \pm 7,5\%$ ;  $p < 0,01$ ) when compared to T2D.

**Conclusion:** Type 2 diabetes and colon cancer are associated with disadvantageous alterations of NK cells population leading to the impairment of their cytotoxic activity. The impaired activity of NK cells in Type 2 diabetes can be involved in the increased cancerogenic risk and promote a higher incidence of colon cancer.

## OP 42 Changes over time in type 1 diabetes

237

**Long-awaited decrease in the incidence of type 1 diabetes in Finnish children under age 15**

V. Harjutsalo<sup>1</sup>, R. Sund<sup>2</sup>, M. Knip<sup>3</sup>, P.-H. Groop<sup>1</sup>;

<sup>1</sup>Folkhälsan Institute of Genetics, Folkhälsan Research Center, Biomedicum Helsinki, <sup>2</sup>National Institute for Health and Welfare, Service Systems Research Unit, <sup>3</sup>Children's Hospital, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland.

**Background and aims:** Increasing incidence in childhood type 1 diabetes has been reported from many countries during the last decades with accelerated increase in some countries. Finland has the highest incidence of type 1 diabetes worldwide, reaching 64.2 per 100 000 people per year in 2005. Our aim was to assess the recent trends in the type 1 diabetes incidence between 2006 and 2010 in Finnish children under the age of 15 years.

**Materials and methods:** Children with newly diagnosed type 1 diabetes in Finland were ascertained from the Hospital Discharge Register, the Drug Reimbursement Register and the Drug Prescription Register during 2006-2010 and compiled by the FinDM diabetes research database. Patients with other types of diabetes were excluded. Age-standardized annual incidence rates and sex and age-specific incidence rates were calculated. Time trends for the incidence rates were estimated by Poisson regression models with sex, age group and year as independent variables. In order to achieve a comprehensive picture of the long-term development of the incidence rate the new data were incorporated into the previous data on incidence (1980-2005) and the trend fluctuation was modeled by Generalized Additive Models.

**Results:** A total of 2 737 children, 1520 boys and 1217 girls, were diagnosed with type 1 diabetes before 15 years of age during 2006-2010. The average age-standardised incidence was 61.2 per 100,000 (95% CI 58.9-63.5), 66.3 (95% CI 63.4-70.1) for boys and 55.7 (95% CI 52.6-59.0) for girls during this period. Incidence decreased each year on average 3.3% (95% CI 0.7-5.8) ( $p = 0.01$ ) from the peak incidence 64.9 per 100 000 per year in 2006 to 56.9 in 2010. The decrease was most striking in the age group 5-9 years. The average age-specific rates were 54.9, 70.4, and 50.0 at ages 0-4 years, 5-9 years, and 10-14-years over the observation period, respectively. Mean age at diagnosis was  $7.03 \pm 3.82$  years in girls and  $7.48 \pm 4.06$  years in boys. Compared to the previous five-year period, between 2001 and 2005, there was no further decrease in age at onset neither in boys nor in girls.

**Conclusion:** The long ongoing increase in the incidence of type 1 diabetes in Finnish children has stopped and the incidence has for the first time decreased since the 1950s. The overall decrease totaled 12.3% from the peak incidence observed in 2006 until the end of 2010. The decrease implies that some environmental exposures that are specific to the early childhood years and that prevailed at the beginning of the 2000s have abated and become less prevalent. However, the incidence is still extremely high in Finnish children and much higher than in any other countries in the world, 56/100 000 per year. Furthermore, the decrease has to be interpreted with caution, since it is still possible that this is only a temporary phenomenon and the incidence may start to increase again.

**Disease progression has changed during the last 30 years among 446 children with newly diagnosed type 1 diabetes located in Scandinavia and Europe**

M.L.M. Andersen<sup>1</sup>, S. Pörksen<sup>1</sup>, P. Hougaard<sup>2</sup>, L.B. Nielsen<sup>1</sup>, J.V. Jørgensen<sup>3</sup>, M. Wallensteen<sup>4</sup>, E. Örtqvist<sup>5</sup>, J.S. Petersen<sup>6</sup>, P. Swift<sup>7</sup>, L. Hansen<sup>1</sup>, H.B. Mortensen<sup>1</sup>;

<sup>1</sup>Pediatrics, Herlev University Hospital, Denmark, <sup>2</sup>Statistics, University of Southern Denmark, Odense, Denmark, <sup>3</sup>Pediatrics, Skejby University Hospital, Århus, Denmark, <sup>4</sup>Pediatrics, Centrallasarettet, Västerås, Sweden, <sup>5</sup>Woman and Child Health, Astrid Lindgrens Children's Hospital, Stockholm, Sweden, <sup>6</sup>Diabetes Biology & Pharmacology, Novo Nordisk A/S, Måløv, Denmark, <sup>7</sup>Children's Hospital, Leicester Royal Infirmary, UK.

**Background and aims:** The purpose of the study was to assess whether the rate of decline in stimulated C-peptide (SCP) from 3-12 months after diag-

nosis in 4 independent paediatric cohorts with different geographic locations has changed over an interval of 30 years. Furthermore the study aimed to examine covariates that predict disease progression rates

**Material and methods:** The rate of decline in SCP levels the first 12 months after diagnosis was compared in 4 paediatric cohorts with type 1 diabetes: 39 children (9.0 yr (range 1.0–17.0 yr), 1982–1985) from the Wallensteen Swedish cohort; 29 placebo treated children (11.6 yr (range 7.4–15.5 yr); 1995 to 1998) from the Örtqvist Swedish Cohort; 251 children (9.0 yr (range 0.2–16.3 yr), 1999 to 2000) from the Hvidoere Remission Phase Cohort and 127 children (10.1 yrs (range 0.6–16.6 yr), 2004 to 2005) from the Danish Remission Phase Cohort. Patients were followed 12 months after diagnosis with a 90-minutes liquid mixed meal challenge after 1, 3, 6, 9, 12 months (if available). Random coefficient regression models were used for analysing the relationship between SCP decline and influencing factors such as age and BMI. At present we perform statistical analyzes including 78 placebo treated children with new onset type 1 diabetes from the placebo groups in the TrialNet cohorts collected in the period 2004–2009

**Results:** Maximum values of SCP were reached 3 months after diagnosis and then declined gradually. The latest cohort had significantly higher SCP values initially ( $p \leq 0.0001$ ) and significantly faster rate of decline in SCP ( $p = 0.05$ ) than the other 3 cohorts, when adjusted for age. The mean rate of decline in SCP for a 10 years old child was 7.7% (Wallensteen), 6.3% (Örtqvist), 7.8% (Hvidoere) and 10.7% (Danish) for the four cohorts, respectively. There was a linear effect of age on the rate of decline in SCP, suggesting 0.7 %/month/year (0.4–0.9) less decline per year of age of the child ( $p < 0.0001$ ). BMI at 3 months had no significant effect on the rate of decline in SCP ( $p = 0.36$ ), by contrast BMI is positively associated to the level of SCP suggesting 7.3 % (3.7–10.8 %) higher C-peptide per 1 kg/m<sup>2</sup> increase in BMI ( $p = 0.0002$ ). The proportion of patients in partial remission as assessed by insulin dose adjusted HbA<sub>1c</sub> (IDAA1c)  $\leq 9$  differed from 35.3% to 47.8% after 6 months and declined to 17.8 to 21.6% 12 months after diagnosis with no significant difference between the cohorts.

**Conclusion:** T1D disease progression seems to have changed during the last 30 years with a tendency toward a more rapid rate of decline in SCP the first 12 months after diagnosis in the latest Danish cohort from 2005. Thus, the environmental factors that possibly explain the increased incidence in T1D in this period might also influence the progression rate of the disease. The rate of decline in SCP is dependent of age but not BMI. Despite higher levels of SCP in the Danish cohort, there are no significant differences in the proportion of children in partial remission.

## 239

### Current mortality risks in the adult type 1 diabetes population of Scotland: high risks at young ages

H.M. Colhoun, on behalf of the Scottish Diabetes Research Network Epidemiology Group; University of Dundee, UK.

**Background and aims:** In a dataset encompassing the entire population of Scotland we examined the current relative risks for mortality and causes of death in people with type 1 diabetes compared with the non-diabetic population.

**Materials and methods:** The Scottish Care Information - Diabetes Collaboration Database that is used in clinical care across Scotland, provided data for 21,789 people with type 1 diabetes aged  $\geq 20$  years. The National Records of Scotland provided the annual numbers of deaths from 2005–2007 for the non-diabetic population of Scotland aged  $\geq 20$  years (3.75 million) and provided numbers and cause of death for those with type 1 diabetes (1,030 deaths). The age adjusted mortality incidence rate ratio (IRR) associated with type 1 diabetes was estimated using Poisson regression.

**Results:** During 2005–2007 the mortality IRR (95% CI) for those with, relative to those without, type 1 diabetes was 2.58 (95% Confidence interval (CI); 2.23–2.98,  $p < 0.001$ ) in men and 2.71 (95% CI 2.18–3.38,  $p < 0.001$ ) in women. The IRR decreased with age being 5.43 (95%CI: 3.50, 8.42) overall at age 20–29 years and 1.82 (95%CI:1.61, 2.06) age  $\geq 70$  years. Of the 123 deaths in 10,173 people  $< 40$  years with type 1 diabetes (rate 4.8/1000 person years at risk), the top three underlying causes were diabetes mellitus (41.4% : of which coma or ketoacidosis accounted for 34 of 51 deaths), other metabolic disorders (12.2% : 15 deaths) and circulatory disease (11.4%: 14 deaths). Among the 907 deaths in those with T1DM age  $\geq 40$  the leading causes were circulatory disease (38.5%: 349 deaths), diabetes mellitus (20.6%: of which coma and ketoacidosis accounted for 37 and renal complications 47 of 187 deaths) and

neoplasm (17.0%: 154 deaths). Overall just 63% of death certificates in those  $< 40$  years and 69% in those  $\geq 40$  years mentioned diabetes.

**Conclusion:** Despite advances in care, type 1 diabetes continues to be associated with substantial elevations in total mortality rates in both sexes with very high relative risks at young ages.

### HbA<sub>1c</sub> and OGTT plasma glucose levels start to rise during the last year before diagnosis in children with multiple autoantibodies and increased genetic risk for type 1 diabetes

O. Helminen<sup>1</sup>, M.-R. Hautakangas<sup>1</sup>, N. Haatanen<sup>1</sup>, T. Pokka<sup>1</sup>, J. Ilonen<sup>2</sup>, O. Simell<sup>3</sup>, M. Knip<sup>4</sup>, R. Veijola<sup>1</sup>;

<sup>1</sup>Dept of Pediatrics, University of Oulu, <sup>2</sup>Immunogenetics Laboratory, University of Turku, <sup>3</sup>Dept of Pediatrics, University of Turku, <sup>4</sup>Inst of Clin Medicine, University of Helsinki, Finland.

**Background and aims:** Few data is available on the development of glucose intolerance before diagnosis of type 1 diabetes. We pictured HbA<sub>1c</sub> and OGTT values over five years before diagnosis in children with advanced beta cell autoimmunity.

**Materials and methods:** Children with increased HLA-conferred risk of type 1 diabetes (T1D) have participated in the type 1 Diabetes Prediction and Prevention (DIPP) Study in Finland. During follow-up the subjects have been screened for islet cell (ICA), glutamic acid decarboxylase (GADA), insulinoma associated antigen-2 (IA-2A) and insulin autoantibodies (IAA) at ages of 3, 6, 12, 18 and 24 months and annually thereafter. Children seroconverting positive for any of the autoantibodies were transferred to a schedule with 3 month (0.25 yr) intervals including also HbA<sub>1c</sub> measurements. When multiple positive autoantibodies occurred oral glucose tolerance tests (OGTT) were performed annually. Our study population consists of 100 children participating in the DIPP follow-up at Oulu University Hospital and who have progressed to T1D before Jan 1, 2012. HbA<sub>1c</sub> study population includes 65 children with HbA<sub>1c</sub> available at diagnosis and at least once during the previous 12 months. OGTT study population consists of 65 children who had been tested with OGTT at least once before diagnosis.

**Results:** Seroconversion to at least one autoantibody occurred at mean age of 2.30 yrs (SD 1.68) and multipositivity at 2.69 yrs (SD 1.88). HbA<sub>1c</sub> and OGTT values before diagnosis are shown in Fig. 1. HbA<sub>1c</sub> values begun to rise 0.75–0.99 yrs before diagnosis when the mean HbA<sub>1c</sub> was 5.66 % (SD 0.49) compared to the mean of 5.39% (SD 0.35) measured between 1.00–4.99 yrs before diagnosis ( $p < 0.001$  in paired sample t-test). Rise in HbA<sub>1c</sub> continued towards diagnosis (mean HbA<sub>1c</sub> 5.74%, SD 0.45 during 0.50–0.74 yrs prior to diagnosis,  $p = 0.04$  in comparison with 5.66% during the previous 0.25 yrs period). OGTT 0 hour and 2 hour glucose levels also rose before diagnosis. Both 0 hour and 2 hour mean values showed significant rise between periods 1.00–4.99 yrs (0 hour: 4.15 mmol/l, SD 0.47; 2 hour: 5.60 mmol/l, SD 1.36) and 0.50–0.99 yrs prior to diagnosis (0 hour: 4.54 mmol/l, SD 0.82; 2 hour: 6.90 mmol/l, SD 2.25);  $p = 0.006$  (0 hours) and  $p = 0.014$  (2 hours). A steep rise continued in 2 hour values when coming closer to diagnosis (mean 2 hour glucose 8.75 mmol/l, SD 4.07 during 0.05–0.49 yrs before diagnosis;  $p = 0.024$  compared to 6.90 mmol/l during the previous 0.50–0.99 yrs period), but the mean 0 hour glucose levels were not significantly different (4.52 mmol/l, SD 0.85 vs. 4.54 mmol/l, SD 0.85, respectively;  $p = 0.105$ ).

**Conclusions:** HbA<sub>1c</sub> and plasma glucose levels in OGTT start to rise as early as 1 year before diagnosis the increase becoming steeper towards the onset of T1D.

## OP 43 SGLT-2 inhibitors

### 241

#### Systematic review and meta-analysis of the efficacy and safety of SGLT2 inhibitors in patients with type 2 diabetes mellitus

A. Tsapas<sup>1,2</sup>, D. Vassilakou<sup>1</sup>, E. Athanasiadou<sup>1</sup>, T. Karagiannis<sup>1</sup>, D.R. Matthews<sup>2,3</sup>,

<sup>1</sup>2nd Medical Department, Aristotle University Thessaloniki, Greece, <sup>2</sup>Harris Manchester College, University of Oxford, UK, <sup>3</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, UK.

**Background and aims:** Sodium-glucose co-transporter 2 (SGLT2) inhibitors are a novel class of oral anti-hyperglycaemic drugs that reduce renal glucose reabsorption. Their therapeutic role in type 2 diabetes has been tested in clinical trials. We performed a systematic review and meta-analyses to assess their efficacy and safety versus placebo or other antidiabetic medications.

**Materials and methods:** We searched Medline, Embase and the Cochrane Library, without any language restrictions, for randomised trials of more than 12 weeks duration that compared an SGLT2 inhibitor with placebo or any other hypoglycaemic medication for type 2 diabetes mellitus. Additionally, we searched websites of pharmaceutical companies, public registries of clinical trials and abstracts of major scientific meetings. Our primary outcome was glycaemic efficacy assessed by the change from baseline in HbA<sub>1c</sub>. Secondary efficacy outcomes included changes in body weight and systolic blood pressure, and percentage of patients achieving HbA<sub>1c</sub> <7%. Safety outcomes included incidence of any hypoglycaemia, adverse events of special interest (urinary and genital tract infections), discontinuation rate and overall cardiovascular morbidity. We conducted meta-analyses using an inverse variance random effects model. Heterogeneity was assessed by the I<sup>2</sup> statistic. Risk of bias was assessed with the Cochrane risk of bias tool.

**Results:** Our search identified 21 eligible trials. Sixteen studies (duration 12–104 weeks, 5030 patients) provided adequate data and were used in our meta-analyses. SGLT2 inhibitors were associated with a greater decline in HbA<sub>1c</sub> compared with placebo (Table). Risk for hypoglycaemia was similar between SGLT2 inhibitors and placebo (risk ratio [RR] 1.10, 95% confidence interval [CI] 0.92 to 1.30) but smaller compared to active comparators (RR 0.24, 95% CI 0.06 to 0.98). No difference in the incidence of urinary tract infections was evident between SGLT2 inhibitors and placebo (RR 1.26, 95% CI 0.94 to 1.70). However, SGLT2 inhibitors were associated with an increased risk for urinary tract infections compared with active comparators (RR 1.51, 95% CI 1.08 to 2.09), and for genital tract infections compared both with placebo (RR 3.28, 95% CI 2.19 to 4.90) or other hypoglycaemic medications (RR 4.57, 95% CI 2.80 to 7.45).

**Conclusion:** Existing data support that SGLT2 inhibitors have a favourable effect on HbA<sub>1c</sub>, weight, systolic blood pressure and incidence of hypoglycaemia. However, they are associated with a significantly increased risk for urinary and genital tract infections.

### 242

#### Dapagliflozin does not impact renal function in patients with type 2 diabetes

A. Ptaszynska<sup>1</sup>, A.-G. Chalamandaris<sup>2</sup>, J. Sugg<sup>3</sup>, K. Johnsson<sup>3</sup>, S. Parikh<sup>3</sup>, J.F. List<sup>1</sup>,

<sup>1</sup>Bristol-Myers Squibb, Princeton, USA, <sup>2</sup>Bristol-Myers Squibb, Braine-l'Alleud, Belgium, <sup>3</sup>AstraZeneca, Wilmington, USA.

**Background and aims:** Dapagliflozin (DAPA), a sodium-glucose cotransporter 2 inhibitor (SGLT2) in development for patients with type 2 diabetes (T2DM), decreases hyperglycemia by inhibiting renal glucose reabsorption, reduces weight, and acts as a mild diuretic with modest blood pressure reduction. Due to its renal mechanism, DAPA's effect on renal function was thoroughly evaluated.

**Materials and methods:** Data were collected from 12 placebo (PBO)-controlled randomized studies involving T2DM patients receiving PBO or DAPA 2.5, 5, or 10 mg. Adverse events (AEs) and lab tests were analyzed up to 24 wk (>4000 patients) for all 12 studies and beyond 24 wk (>3000 patients) for 6 of these 12 studies. Estimated glomerular filtration rate (eGFR) was calculated using the abbreviated Modification of Diet in Renal Disease equation.

**Results:** In the 12 placebo-controlled studies, approximately one-third (36.9–39.7%) of patients had baseline (BL) eGFR > 90 mL/min/1.73m<sup>2</sup>, half (52.8–54.4%) had BL mean eGFR ranging from ≥60 to <90 mL/min/1.73m<sup>2</sup> and 7.5–9.3% of the patients had BL eGFR ranging from ≥30 to <60 mL/min/1.73m<sup>2</sup>. At week 1, eGFR decreased from BL by -2.75, -2.92, and -4.15 mL/min/1.73m<sup>2</sup> for dapagliflozin 2.5, 5, and 10 mg, respectively, but returned to or above BL by Wk 24. In the 6 studies, a similar pattern was observed up to Wk 24 and was maintained to Wk 102. Mean serum creatinine (Cr) changed minimally (±0.01 and ±0.022 mg/dL) from BL to Wk 24 and Wk 102, respectively, in all groups. DAPA had no adverse effect on albuminuria, assessed as urinary albumin: Cr ratio or shift in normal, micro-, or macro- albuminuria category through 102 wk. Renal AEs in the DAPA group were similar to PBO through 24 wk but were reported slightly more frequently through 102 wk (Table). The most commonly reported renal AE was serum creatinine increase; there were no reports of acute nephrotoxicity through 102 wk. The moderate renal impairment (BL eGFR ≥30 and <60 mL/min/1.73m<sup>2</sup>) subgroup (n=74–107) had the highest proportion of patients with renal adverse events compared to the subgroups with BL eGFR ≥60 to <90 and ≥90 mL/min/1.73m<sup>2</sup> up to 24 wk. Few AEs corresponding to volume depletion were reported up to 24 wk (Table). At Wk 24, mean decreases in seated blood pressure (both systolic and diastolic) with DAPA were larger compared to PBO, with no apparent dose dependence, and persisted up to 102 wk. No mean changes from BL in serum electrolytes (Na, K, HCO<sub>3</sub>, or Cl) were observed with DAPA and PBO in either analysis period; slight increases were seen in serum Mg and phosphorus at Wk 24 but not Wk 102.

**Conclusion:** DAPA treatment is not associated with increased risk of acute renal toxicity or deterioration of renal function. In addition to blood pressure lowering associated with DAPA, improved glycemic control and effects of weight reduction may support preservation of kidney function in patients with T2DM.

# Efficacy and safety of canagliflozin, a sodium glucose co-transporter 2 inhibitor, compared with sitagliptin in patients with type 2 diabetes on metformin plus sulphonylurea

G. Scherthaner<sup>1</sup>, J. Gross<sup>2</sup>, M. Fu<sup>3</sup>, J. Yee<sup>3</sup>, M. Kawaguchi<sup>3</sup>, W. Canovatchel<sup>3</sup>, G. Meininger<sup>3</sup>

<sup>1</sup>Rudolfstiftung Hospital-Vienna, Austria, <sup>2</sup>Hospital de Clinicas de Porto Alegre, Brazil, <sup>3</sup>Janssen Research & Development, L.L.C., Raritan, USA.

**Background and aims:** Canagliflozin (CANA) is an inhibitor of the sodium glucose co-transporter 2 being developed for the treatment of patients with type 2 diabetes mellitus (T2DM). This 52-week study evaluated the efficacy and safety of CANA 300 mg compared with sitagliptin (SITA) in subjects with T2DM inadequately controlled with metformin (MET) plus a sulphonylurea (SU).

**Materials and methods:** In this randomised, double-blind, active-controlled, Phase 3 study (N = 755), subjects with T2DM inadequately controlled with MET + SU received CANA 300 mg or SITA 100 mg once daily. Changes from baseline in glycaemic and other efficacy endpoints were assessed at Week 52. Adverse events (AEs) were recorded throughout the study.

**Results:** Mean baseline characteristics were similar across groups (age, 56.7 years; HbA<sub>1c</sub>, 8.1%; body weight, 88.3 kg; body mass index, 31.6 kg/m<sup>2</sup>). As shown in the Table, HbA<sub>1c</sub> was reduced from baseline at 52 weeks with CANA 300 mg and SITA 100 mg. CANA 300 mg demonstrated non-inferiority as well as superiority to SITA 100 mg in reducing HbA<sub>1c</sub> ( $P < 0.001$ ). CANA 300 mg provided consistently lower HbA<sub>1c</sub> values over 52 weeks while HbA<sub>1c</sub> increased with SITA 100 mg after Week 12. CANA 300 mg also showed greater reduction in body weight and improvement in fasting plasma glucose (FPG) and systolic blood pressure (BP) compared with SITA 100 mg. CANA 300 mg showed numerical improvement in high-density lipoprotein cholesterol (HDL-C) and was associated with a slight increase in low-density lipoprotein cholesterol (LDL-C) compared with SITA 100 mg.

Table. Summary of Efficacy Endpoints at Week 52 (LOCF)

Parameter <sup>a,b</sup>	CANA 300 mg (N = 377)	SITA 100 mg (N = 378)
HbA <sub>1c</sub> change, %	-1.03 (0.05)	-0.66 (0.05)
Difference vs SITA	-0.37 (-0.50, -0.25) <sup>c,d</sup>	
FPG change, mmol/L	-1.7 (0.1)	-0.3 (0.1)
Difference vs SITA	-1.3 (-1.7, -1.0) <sup>d,e</sup>	
Body weight % change	-2.5 (0.2)	0.3 (0.2)
Difference vs SITA	-2.8 (-3.3, -2.2) <sup>d,e</sup>	
Systolic BP change, mmHg	-5.1 (0.7)	0.9 (0.7)
Difference vs SITA	-5.9 (-7.6, -4.2) <sup>d,e</sup>	
Diastolic BP change, mmHg	-3.0 (0.4)	-0.3 (0.4)
Difference vs SITA	-2.7 (-3.8, -1.7)	
Triglycerides % change	9.6 (2.8)	11.9 (2.9)
Difference vs SITA	-2.3 (-9.8, 5.3) <sup>f</sup>	
LDL-C % change	11.7 (1.8)	5.2 (1.8)
Difference vs SITA	6.4 (1.7, 11.2)	
HDL-C % change	7.6 (0.9)	0.6 (0.9)
Difference vs SITA	7.0 (4.6, 9.3) <sup>g</sup>	
LDL-C/HDL-C % change	6.1 (2.0)	7.2 (2.0)
Difference vs SITA	-1.1 (-6.3, 4.2)	

LOCF, last observation carried forward; SE, standard error; CI, confidence interval; ANCOVA, analysis of covariance; NS, not significant. <sup>a</sup>Least squares mean (SE) change from baseline using ANCOVA and SITA-subtracted mean (95% CI) values; <sup>b</sup>P values are reported for pre-specified comparisons only; <sup>c</sup>Upper limit of 95% CI less than pre-specified non-inferiority margin of 0.3% for the comparison to SITA; <sup>d</sup>Upper limit of 95% CI <0.0% for the comparison to SITA; <sup>e</sup>P <0.001 vs SITA; <sup>f</sup>P = NS vs SITA; <sup>g</sup>Not significant due to multiplicity control.

The overall incidence of AEs was similar with CANA 300 mg (76.7%) and SITA 100 mg (77.5%). Rates of serious AEs (6.4% vs 5.6%) and AE-related discontinuations (5.3% vs 2.9%) were low and similar for CANA 300 mg and SITA 100 mg. Incidences of AEs consistent with superficial genital fungal infections were higher with CANA 300 mg than with SITA 100 mg in women (15.3% vs 4.3%) and men (9.2% vs 0.5%). No differences were observed between CANA 300 mg and SITA 100 mg in the incidences of urinary tract infections (4.0% vs 5.0%) and osmotic diuresis-related AEs (eg, pollakiuria; <3% per specific AE). The proportion of subjects with ≥1 hypoglycaemia episode were similar with CANA 300 mg (43.2%) and SITA 100 mg (40.7%).

**Conclusion:** CANA 300 mg showed improvements in glycaemic control, body weight reduction, and systolic BP over 52 weeks compared with SITA 100 mg, and was well tolerated in subjects with T2DM inadequately controlled with MET + SU.

# Canagliflozin lowers postprandial plasma glucose and insulin excursions by delaying intestinal glucose absorption in addition to increasing urinary glucose excretion

S. Mudaliar<sup>1</sup>, T.P. Ciaraldi<sup>1</sup>, S. Sha<sup>2</sup>, A. Ghosh<sup>2</sup>, D. Polidori<sup>2</sup>, R.R. Henry<sup>1</sup>

<sup>1</sup>University of California, San Diego, <sup>2</sup>Janssen Research & Development, L.L.C., Raritan, USA.

**Background and aims:** Canagliflozin (CANA), a potent sodium glucose co-transporter 2 (SGLT2) inhibitor, is also a low-potency SGLT1 inhibitor. During drug absorption, intestinal CANA levels post-dose may be sufficiently high to transiently inhibit intestinal SGLT1. This study tested the hypothesis that CANA 300 mg would delay intestinal glucose absorption in healthy subjects during a mixed-meal tolerance test (MMTT).

**Materials and methods:** A 2-period crossover study in 20 healthy subjects (mean ± standard deviation [SD] age = 26 ± 6 yr; body weight = 78 ± 10 kg) assessed the effects of a single 300-mg dose of CANA on intestinal glucose (G) absorption using a dual tracer method (IV <sup>3</sup>H-G and oral <sup>14</sup>C-G). Placebo (PBO) or CANA was given 20 min prior to a 600 kcal MMTT containing 75 g of G and 960 mg of acetaminophen. Plasma G, <sup>3</sup>H-G, <sup>14</sup>C-G, acetaminophen, and insulin were measured frequently for 6 h. These values were used to calculate the rate of appearance in plasma of oral G (R<sub>a</sub>G), endogenous G production, and G disposal; acetaminophen concentrations were used as an index of gastric emptying. Plasma glucose-dependent insulinotropic peptide (GIP), peptide YY (PYY), and glucagon like peptide-1 (GLP-1) were measured over the first 2 h and incremental areas under the curves (AUCs) were calculated.

**Results:** CANA was well tolerated. CANA delayed R<sub>a</sub>G (Figure A) and reduced cumulative R<sub>a</sub>G (AUC R<sub>a</sub>G) by 31% at 1 h (geometric mean PBO = 381 vs CANA = 264 mg/kg;  $P < 0.001$ ) and by 20% at 2 h (PBO = 723 vs CANA = 576 mg/kg;  $P = 0.002$ ); this was nearly matched by increased R<sub>a</sub>G over 2–6 h, so that AUC R<sub>a</sub>G over 0–6 h was only approximately 6% lower for CANA than PBO (PBO = 1018 vs CANA = 960 mg/kg;  $P = 0.003$ ), consistent with the lack of notable malabsorption. Plasma acetaminophen concentrations were reduced by approximately 10% over 0–2 h in CANA-treated subjects, suggesting a modest delay in gastric emptying. CANA also increased urinary glucose excretion (UGE) over 0–2 h (PBO <0.2 g; CANA = 6 ± 3 g;  $P < 0.001$ ) and 2–6 h (PBO <0.1 g; CANA = 12 ± 4 g;  $P < 0.001$ ). Total G disposal over 0–6 h was similar for PBO and CANA (PBO = 130 g vs CANA = 132 g;  $P = 0.78$ ). Treatment with CANA decreased plasma GIP (PBO = 63.5 vs CANA = 30.1 pM-h;  $P < 0.001$ ) and increased plasma PYY (PBO = 13.6 vs CANA = 21.9 pM-h;  $P = 0.01$ ) and total GLP-1 (PBO = 10.1 vs CANA = 13.7 pM-h;  $P = 0.07$ ).

**Conclusion:** CANA reduces postprandial plasma G and insulin excursions (Figures B and C) by both increasing UGE (due to renal SGLT2 inhibition) and delaying R<sub>a</sub>G (likely due to intestinal SGLT1 inhibition, with a possible additional contribution from delayed gastric emptying). The changes observed in the gut peptides in CANA-treated subjects (reduced GIP and increased PYY and GLP-1) suggest reduced G absorption from the upper intestine and increased absorption from the lower intestine, consistent with the hypothesis that CANA treatment transiently inhibits intestinal SGLT1.

## OP 44 Mechanisms of incretin action

### 245

#### Mechanisms of glucose lowering in type 2 diabetes patients treated with sitagliptin alone or in combination with metformin: a double tracer study

C. Solis-Herrera, C. Triplitt, J. Garduno-Garcia, J. Adams, R.A. DeFronzo, E. Cersosimo;  
Medicine/Diabetes, University of Texas, San Antonio, USA.

**Background and aims:** Little is known about glucose lowering mechanisms of sitagliptin and metformin in type 2 diabetes treatment. We examined glucose kinetics and hormonal changes in response to sitagliptin (S), metformin (M), used either as monotherapy or in combination (S+M).

**Materials and methods:** Sixteen T2DM (age~52yrs, 10F/6M, 1yr duration, BMI~32 kg/m<sup>2</sup>, HbA<sub>1c</sub>=8.4±1.2%) were randomized to 4 therapy periods (6wks + 2wk washout) with either Placebo (P), (M), (S) or (S+M) at maximum doses. After each 6wk period, they received a meal tolerance test (MTT, 600 kcal, 20g protein, 25g fat and 75g glucose) labeled with [<sup>14</sup>C-glu] to calculate oral glucose appearance rates (RaO); [<sup>3</sup>H-glu] IV infusion for glucose appearance rates (RaT) & disappearance (RdT). Endogenous glucose production (EGP) equals RaT-RaO. Fasting plasma glucose (FPG), insulin (FPI), glucagon (FPGn) and post-MTT levels were measured over 360 minutes. Plasma incretin levels (intact GLP-1 and GIP) and insulin secretory rate (ISR) (plasma C-peptide deconvolution) were also determined.

**Results:** FPG decreased from 165±10 (P) to 145±6 (M), to 149±9 (S), and to 125±5 mg/dl (S+M); mean post-MTT glucose levels in (P) of 208±15 mg/dl decreased to 181±11 (M), 182±13 (S), and 155±9 (S+M) [p<0.01]. Basal HGP fell from 2.1±0.1 (P) to 1.9±0.2 (M), 1.8±0.1 (S), and to 1.5±0.1 mg/kg.min (S+M) [p<0.05]. Mean RaT post-MTT was lower in (S)=2.5±0.1, (M)=2.7±0.1 and (S+M)=2.3±0.1 than in (P)=2.9±0.2 mg/kg.min [p<0.05]. RaO was similar after all therapies (~1.9-2.3 mg/kg.min), therefore the decline in RaT was due to a drop in HGP post-MTT from 0.8±0.1 (P) to 0.4±0.1 (M), 0.6±0.1 (S) and 0.4±0.1 (S+M) [p<0.05]. Mean RdT post-MMT was equal (~2.1-2.3 mg/kg.min). FPI did not change (~12 µU/ml) in any group but the peak ISR (~13 pmol/kg.min) during MTT was higher in (S+M) than (M)=11±1, (S)=11±1 and (P)=10±1, reflecting a greater rise in mean post-MTT insulin in (S+M)=76±9 vs. (P)=51±9, (S)=52±8 and (M)=56±3 µU/ml, [p<0.05]. FPGn did not change (~70 pg/ml) in any group but greater suppression in plasma glucagon post-MTT was seen in (S+M)=32±3% and (S)=26±3% vs. (P)=14±2% and (M)=13±4%, [p<0.05]. Fasting intact GLP-1 (pM) was higher in S (10.1±1.4) and S+M (16.9±2.2) than P (6.9±1.0) and M (5.5±0.6), and mean post-MMT levels also were higher in S (24.6±1.8) and S+M (32.6±1.6) than P (11.7±0.8) and M (13.7±1.0), [p<0.001]. Fasting plasma GIP (~38-49 pg/ml) and the 4-fold post-MMT increase (~153-163 pg/ml) were equal in all groups.

**Conclusion:** Our findings indicate that sitagliptin and metformin reduce fasting and post-meal hyperglycemia to the same extent, via different mechanisms. Metformin directly suppresses hepatic glucose production whereas sitagliptin exerts a comparable effect indirectly by increasing plasma GLP-1 with significant glucagon inhibition. In addition to these mechanisms both agents (S+M) exert greater glucose lowering effect by also stimulating post-meal insulin secretion.

### 246

#### Degree of DPP-4 inhibition after sitagliptin treatment estimated from intact and total GLP-1 and GIP responses to oral glucose in patients with type 2 diabetes

I. Vardarli<sup>1</sup>, E. Arndt<sup>1</sup>, C.F. Deacon<sup>2</sup>, J.J. Holst<sup>2</sup>, L.D. Köthe<sup>1</sup>, O. Baranov<sup>1</sup>, M.A. Nauck<sup>1</sup>;

<sup>1</sup>Diabeteszentrum Bad Lauterberg, Bad Lauterberg im Harz, Germany,

<sup>2</sup>Department of Biomedical Sciences, Panum Institute, Univ. of Copenhagen, Denmark.

**Background and aims:** Typically, intact GLP-1 concentrations are 15-20 % of total GLP-1 concentrations, but DPP-4 inhibitor treatment only increases intact GLP-1 concentrations by 2-3fold. This discrepancy can either be explained by other interferences (e.g., L cell feedback inhibition mediated by increased concentrations of intact GLP-1) or by an incomplete DPP-4 inhibition in the relevant compartment, e.g. the gut mucosa. The aim of the present

study was to estimate the degree of inhibition of DPP-4 activity in the gut mucosa from concentrations of intact and total GLP-1 (or GIP) determined with and without sitagliptin treatment.

**Materials and methods:** 20 patients with type 2 diabetes (age:  $59 \pm 7$  yrs., duration of diabetes  $5.1 \pm 2.7$  yrs.,  $HbA_{1c}$ :  $7.0 \pm 0.6$  %, BMI  $31.2 \pm 3.2$  kg/m<sup>2</sup>, means  $\pm$  SD, drug-naïve/OAD monotherapy, 6 weeks wash-out) entered a 4-period crossover trial with placebo, sitagliptin (S; 100 mg/d), metformin (M; escalation to 2000 mg/d), and M/S combination (order randomized). On day 5, an oral glucose challenge (75 g) was performed. GLP-1 and GIP (total and intact) were determined by specific RIA.

**Results:** Integrated incremental responses of GLP-1 and GIP are displayed in the table. With placebo treatment, responses of intact GLP-1 were 19.4 % of those for total GLP-1. Sitagliptin treatment induced a 1.71fold (monotherapy;MT) and 1.68fold (metformin background;MB) increment in intact GLP-1, taking the level to 33.3 % of the total GLP-1 under placebo conditions. Total GLP-1 was reduced by sitagliptin treatment (MT: -53.0 %; MB: -46.5 %), indicating L-cell feedback inhibition. Correcting the sitagliptin-induced rise in intact GLP-1 for the degree of feedback inhibition raised intact GLP-1 responses to 70.9 % of the total GLP-1 responses with placebo. With placebo treatment, responses of intact GIP were 30.9 % of those for total GIP. Sitagliptin treatment induced a 1.81fold (MT) and 2.39fold (MB) increment in intact GIP, taking the level to 55.9 % of the total GIP under placebo conditions. Total GIP was reduced by sitagliptin treatment (MT: -28.4 %; MB: -31.3 %), indicating K-cell feedback inhibition. Correcting the sitagliptin-induced rise in intact GIP for the degree of feedback inhibition raised intact GLP-1 responses to 77.8 % of the total GIP responses with placebo.

**Conclusion:** The increment in intact GLP-1 and GIP concentrations with DPP-4 inhibition (sitagliptin treatment) is limited by concurrent L- and K-cell feedback inhibition. A correction for this feedback inhibition does not lead to intact GLP-1 and GIP levels equal to total GLP-1 and GIP, respectively. This may indicate a lesser degree of inhibition of DPP-4 in the relevant compartment(s), e.g. the gut mucosa, than has previously been reported for serum DPP-4 inhibition (> 85 %).

Integrated incremental responses of GLP-1 and GIP (pmol.l<sup>-1</sup>.min) after oral glucose loads (75 g)

Parameter	Experimental conditions				p-values (ANCOVA)		
	Placebo	Sitagliptin	Metformin	Sitagliptin + Metformin	Sitagliptin	Metformin	Interaction
Intact GLP-1	200 $\pm$ 45	342 $\pm$ 89	295 $\pm$ 56	495 $\pm$ 126	0.044	0.14	0.73

## 247

### Effects of a xylose preload, with or without sitagliptin, on gastric emptying and postprandial glycaemia in type 2 diabetes

T. Wu, B.R. Zhao, M. Horowitz, K.L. Jones, C.K. Rayner;  
Discipline of Medicine, University of Adelaide, Australia.

**Background and aims:** Fat and protein 'preloads' taken before a meal can reduce postprandial glycaemic excursions in health and type 2 diabetes, at least in part, by slowing gastric emptying (GE) and stimulating GLP-1, but entail additional energy intake. It is not known whether the combination of a 'preload' with a dipeptidyl peptidase-4 (DPP-4) inhibitor would improve efficacy. We have evaluated the effects of a xylose preload, which yields relatively low energy, with or without sitagliptin, on postprandial glycaemia and GE in type 2 diabetes.

**Materials and methods:** 10 type 2 patients were studied on 4 occasions each in randomised, double-blinded, fashion. Subjects took either 100 mg sitagliptin or placebo the night before each study (~2200h). At 0830h after an overnight fast, they drank a 200 mL 'preload', containing either 50 g xylose, or 80 mg sucralose (control of equivalent sweetness) (i.e. the four treatments were sitagliptin + xylose (SX), sitagliptin + control (SC), placebo + xylose (PX), and placebo + control (PC)). 40min later, they ate a mashed potato meal labeled with 100  $\mu$ g <sup>13</sup>C-octanoic acid. Blood glucose and GE (breath test) were evaluated for 4h. Data are mean  $\pm$  SEM.

**Results:** Both the peak and range (i.e. maximum minus minimum value) of postprandial blood glucose concentrations were highest after PC (peak  $14.3 \pm 0.7$  mmol/L, range  $8.6 \pm 0.6$  mmol/L), and lowest after SX (peak  $11.9 \pm 0.5$  mmol/L, range  $5.4 \pm 0.5$  mmol/L) ( $P < 0.001$  for each), while there was no difference between SC (peak  $12.8 \pm 0.6$  mmol/L, range  $7.1 \pm 0.6$  mmol/L) and PX (peak  $12.8 \pm 0.7$  mmol/L, range  $6.3 \pm 0.6$  mmol/L). GE was slower after xylose than control (half-emptying time (T50) for PX  $223 \pm 28$  min and SX  $253 \pm 25$  min vs PC  $153 \pm 7$  min and SC  $167 \pm 13$  min,  $P < 0.0001$ ), without any effect of sitagliptin. The postprandial glycaemic range was inversely associated with the T50 ( $r = -0.50$ ,  $P = 0.001$ ).

**Conclusion:** The combination of a DPP-4 inhibitor with a low nutrient 'preload' represents a promising strategy for the management of type 2 diabetes.

### Reduced incretin effect in truncally vagotomised subjects

A. Plamboeck<sup>1,2</sup>, S. Veedfald<sup>1,3</sup>, C.F. Deacon<sup>2</sup>, A. Wettergren<sup>3</sup>, L.B. Svendsen<sup>3</sup>, S. Meisner<sup>4</sup>, C. Hovendahl<sup>5</sup>, J.J. Holst<sup>2</sup>, E.K. Knop<sup>1</sup>, T. Vilsbøll<sup>1</sup>;

<sup>1</sup>Diabetes Research Division, Department of internal medicine, Gentofte Hospital, University of Copenhagen, Hellerup, <sup>2</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, Department of Biomedical Sciences, Panum Institute, University of Copenhagen, <sup>3</sup>Department of Surgical Gastroenterology, and Liver Transplantation, Rigshospitalet, University of Copenhagen, <sup>4</sup>Department of Surgical Gastroenterology, Bispebjerg Hospital, University of Copenhagen, <sup>5</sup>Department of Surgical Gastroenterology, Odense University Hospital, University of Southern Denmark, Denmark.

**Background and aims:** Rapid degradation of glucagon-like peptide-1 (GLP-1) by dipeptidyl peptidase 4 suggests that GLP-1 may act locally (through vagal afferents) before being degraded. The aim of the current study was to clarify the role of vagal innervation on the incretin effect.

**Materials and methods:** Ten truncally vagotomised subjects (due to duodenal ulcer) with pyloroplasty (68 $\pm$ 2 years; fasting plasma glucose (FPG): 6.0 $\pm$ 0.2 mmol/l), 10 subjects treated for oesophageal cancer with cardia resection including truncal vagotomy/pyloroplasty (65 $\pm$ 2 years; FPG: 5.8 $\pm$ 0.3 mmol/l) and 10 control subjects (67 $\pm$ 1 years; FPG: 5.3 $\pm$ 0.1 mmol/l) underwent 4h 50 g-OGTT and isoglycaemic glucose infusion (IIGI).

**Results:** Isoglycaemia during the oral and iv glucose administration was obtained. Peak plasma GLP-1 levels were ~5-fold higher (109 $\pm$ 19 and 140 $\pm$ 40 vs. 24 $\pm$ 3 pmol/l,  $p < 0.02$ ) and gastric emptying faster (paracetamol  $T_{max}$ : 38 $\pm$ 7 and 33 $\pm$ 7 vs. 77 $\pm$ 8 min,  $p < 0.002$ ) in vagotomised subjects after OGTT compared to controls. Glucagon concentrations were suppressed similarly after both iv (total area under the curve (tAUC): 1184 $\pm$ 147 4h $\times$ pmol/l) and oral glucose (1292 $\pm$ 180 4h $\times$ pmol/l,  $p = NS$ ) in controls, whereas vagotomised subjects suppressed glucagon during IIGI and exhibited hyperglucagonemic responses following OGTT (vagotomy: 1374 $\pm$ 174 vs. 1891 $\pm$ 276 4h $\times$ pmol/l,  $p < 0.05$ ; cardia resection: 1125 $\pm$ 139 vs. 1608 $\pm$ 237 4h $\times$ pmol/l,  $p < 0.05$ ). The incretin effect was reduced in the vagotomised groups (48 $\pm$ 7% (vagotomy), 45 $\pm$ 5% (cardia resection,  $p = NS$ ) compared to the controls (64 $\pm$ 6%,  $p < 0.05$ ).

**Conclusion:** The incretin effect was diminished in vagotomised subjects despite 5-fold higher OGTT-induced GLP-1 levels. Furthermore, vagotomised subjects had inappropriate glucagon responses after an oral glucose load. These findings may indicate that an intact vagal innervation is important for the effect of GLP-1 and thereby maintenance of normal glucose homeostasis.

### Psychological impact of diabetes and clinical outcomes: do women with type 2 diabetes require more intense and specific support?

A. Nicolucci<sup>1</sup>, S. Gentile<sup>2</sup>, G. Lucisano<sup>1</sup>, G. Marra<sup>3</sup>, F. Pellegrini<sup>1</sup>, M.C. Rossi<sup>1</sup>, G. Vespasiani<sup>4</sup>, BENCH-D Study Group;

<sup>1</sup>Consorzio Mario Negri Sud, S. Maria Imbaro <sup>2</sup>Federico II University, Naples, <sup>3</sup>NovoNordisk Italia, Rome, <sup>4</sup>Madonna del Soccorso Hospital, S. Benedetto del Tronto, Italy.

**Background and aims:** Patient-centered outcomes are considered of primary importance in the management of chronic conditions. We evaluated the impact of gender on psychological well-being and diabetes related stress in type 2 diabetes (T2DM) patients.

**Materials and methods:** Overall, 28 Italian diabetes outpatient clinics identified a random sample of patients who filled in the WHO-5 well-being index and the Problem Areas in Diabetes (PAID-5) questionnaires. The WHO-5 score ranges between 0 and 100; a score  $\leq 28$  is an indication for testing for depression; the PAID-5 score ranges between 0 and 100, and higher scores indicate poorer adaptation to diabetes. Additional questionnaires were: Diabetes Empowerment Scale (DES), Barriers to Medications (BM), and Global Satisfaction for Diabetes Treatment (GSDT). Clinical data were extracted from computerized medical records. Multiple logistic regression models adjusted for socio-demographic and clinical characteristics were applied to investigate the likelihood to have a WHO-5 or a PAID-5 score in the worst quartile.

**Results:** Overall, 2434 patients were evaluated (mean age  $65.0 \pm 10.2$  years, diabetes duration  $13.8 \pm 15.2$  years, 59.9% males, 48.6% treated with OHA, 25.3% treated with insulin+OHA, 24.3% treated with insulin). Female patients showed lower levels of psychological well-being than males (WHO-5 score of  $50.8 \pm 23.2$  vs.  $62.0 \pm 21.6$ ;  $p < 0.001$ ) and worse adaptation to diabetes (PAID-5 score of  $49.0 \pm 29.0$  vs.  $41.0 \pm 29.0$ ;  $p < 0.001$ ). After adjusting for socio-demographic and clinical characteristics, the likelihood of having a WHO-5 score in the lowest quartile was two times higher in women than in men (OR=1.99; 95%CI 1.51–2.63). Similarly, the likelihood of having a PAID-5 score in the worst quartile was 57% higher in women than in men (OR=1.57; 95%CI 1.17–2.10). Significantly worse levels of PAID-5 score were found in women not reaching the HbA1c target  $\leq 7\%$  as compared with those reaching the target ( $52.9 \pm 27.4$  vs.  $45.4 \pm 27.5$ ;  $p = 0.0003$ ); no association between PAID-5 score and HbA1c target was found in men. Higher levels of diabetes related stress and lower levels of psychological well-being were associated with lower levels of satisfaction with treatment (GSDT) ( $R = -0.30$ ;  $p < 0.0001$  for PAID-5 and  $R = 0.22$ ;  $p < 0.0001$  for WHO-5), lower levels of diabetes empowerment (DES) ( $R = -0.25$ ;  $p < 0.0001$  for PAID-5 and  $R = 0.28$ ;  $p < 0.0001$  for WHO-5), and higher levels of perception of barriers to medication (BM) ( $R = 0.22$ ;  $p < 0.0001$  for PAID-5 and  $R = -0.21$ ;  $p < 0.0001$  for WHO-5).

**Conclusion:** Female gender is associated with poorer psychological well-being and adaptation to diabetes, which in turn are associated with patient attitudes and the achievement of the desired target. These findings suggest the need for enhanced psychological support and specific education in women with T2DM.

### Lifetime depression and type 2 diabetes: the Fremantle diabetes study phase II

W.A. Davis<sup>1</sup>, T.M.E. Davis<sup>1</sup>, S.E. Starkstein<sup>2</sup>, D.G. Bruce<sup>1</sup>;

<sup>1</sup>School of Medicine and Pharmacology, <sup>2</sup>School of Psychiatry & Clinical Neurosciences, University of Western Australia, Fremantle, Australia.

**Background and aims:** There is a bi-directional association between depression and type 2 diabetes (T2DM). Depression occurring after diabetes diagnosis may reflect the burden of disease and/or its complications and have different causes, clinical features and management than depressive illness that develops before diagnosis. Our aim was to compare the characteristics of T2DM in patients in which depression pre-dated diabetes (Group 1) with those of patients developing depression after diabetes diagnosis (Group 2) in a large representative cohort.

**Materials and methods:** The longitudinal observational Fremantle Diabetes Study Phase II recruited 1,551 patients with T2DM from an urban Australian

community between 2008 and 2011. The 9-item Patient Health Questionnaire (PHQ9) was part of detailed baseline assessment. The PHQ9 was modified to assess lifetime depression and age at first depressive episode (PHQ9 Lifetime), and was validated against DSM-IV criteria in a sub-group of patients. The standard PHQ9 questionnaire, which defined the presence and severity of any (major or minor) current depression, was completed by 1443 (93%) and the PHQ9 lifetime questionnaire by 1,384 (89%).

**Results:** In the 1,384 with complete data (mean age 66.2 years; 52.9% males), 288 (20.8%) had a history of depression of whom 193 (67.0%) were in Group 1 and 95 (33.0%) in Group 2. The onset of first depression occurred a median of 13.6 years before diabetes diagnosis at a mean age of 37.3 years in Group 1 and a median of 7.1 years after diabetes diagnosis at a mean 58.4 years of age in Group 2. Compared with Group 1 participants, those in Group 2 were significantly more centrally obese, younger at diabetes diagnosis, and had longer diabetes duration, worse glycaemic control, more intensive blood glucose-lowering treatment, a greater burden of microvascular complications and a higher prevalence of self-reported intermittent claudication ( $P \leq 0.05$ ). Similar proportions of participants in the two groups were currently depressed (24.9% vs 34.7% in Groups 1 and 2, respectively,  $P = 0.10$ ) and taking antidepressant medications (26.4% vs 31.6%,  $P = 0.40$ ), but the percentage of Group 1 patients with controlled depression (no current PHQ9 depressive symptoms on treatment) was significantly greater than that in Group 2 (41.5% vs 23.3%,  $P = 0.050$ ). The prevalence of untreated depression was similar (37.8% vs 30.2%,  $P = 0.44$ ). Compared with participants without a lifetime history of depression, both Groups reported significantly lower compliance with taking diabetes medications (both  $P \leq 0.01$ ).

**Conclusion:** The lifetime risk of depression in patients with T2DM is very high. Depression precedes the development of diabetes in most cases. Depression occurring after diabetes diagnosis is associated with an earlier onset and longer duration of diabetes, more complex treatment and an increased risk of vascular complications. These patients appear to be relatively resistant to antidepressive therapy, suggesting a distinct underlying pathophysiology. The temporal relationship between depression and diabetes may have important implications for clinical management.

### The reach of screening for and treating of subsyndromal depression in type 2 diabetic patients

M. Pibernik-Okanovic<sup>1</sup>, M. Sekerija<sup>2</sup>, D. Ajdukovic<sup>1</sup>, N. Hermanns<sup>3</sup>;

<sup>1</sup>Vuk Vrhovac University Clinic for Diabetes, <sup>2</sup>Croatian National Institute of Public Health, Zagreb, Croatia, <sup>3</sup>Research Institute of the Diabetes Academy Mergentheim (FIDAM), Bad Mergentheim, Germany.

**Background and aims:** Elevated depressive symptoms, common in diabetic patients, have suboptimal recognition and treatment rates. This study aimed to assess the reach of depression screening followed by treatment programmes for subsyndromal depression in a large sample of type 2 diabetic patients, and determine predictors of patients' participation in treatment.

**Materials and methods:** A sample of 4196 type 2 patients (44% female, aged  $56 \pm 8$  yrs, educated for  $12 \pm 3$  yrs, with diabetes duration of  $10 \pm 7$  yrs, BMI of  $30 \pm 5$  kg/m<sup>2</sup> and HbA1C of  $7.2 \pm 1.4$ ) was screened for depressive symptoms. They were sent the two-item Patient Health Questionnaire-Depression scale (PHQ-2) accompanied by an additional question inquiring into the need to receive professional help in mood-related issues. Disease-related data (BMI, diabetes duration, HbA1C, total cholesterol, LDL, HDL, triglycerides and creatinine) were extracted from the electronic files. Patients with positive screening results were phoned to collect personal data (professional, economic and family status, and self-reported acute and chronic stress) and to assess the severity of depressive symptoms by a structured clinical interview (SCID-I). Patients classified as having subclinical depressive symptoms were invited to be randomized to a psychoeducational, physical exercise or diabetes re-education treatment group. The reach of the screening procedure was evaluated based on the total response rate, the proportion of positive depression screenings, and the proportion of eligible patients who entered the treatment programmes. Demographic and disease-related characteristics were explored in patients with elevated depressive symptoms vs. depression-free patients by using chi-square and t-tests. Multivariate logistic regression analysis was used to determine which demographic and disease-related factors differentiated between individuals who entered the treatment and those who declined to participate.

**Results:** Of the 34% of patients who returned the questionnaire ( $n = 1420$ ), 40% reported elevated depressive symptoms and a need for professional help

( $n=581$ ). One-half (48%,  $n=282$ ) were considered eligible for treatments, with 191 (68%) entering the treatment programmes and 91 declining to do so. Responsiveness to screening, reporting depressive symptoms and expressing a need for help were comparable in female and male respondents (all  $p$ 's  $>0.05$ ). Treatment participants in comparison with non-participants had lower BMI ( $29 \text{ kg/m}^2 \pm 4.3$  vs.  $31 \text{ kg/m}^2 \pm 4.9$ ,  $p=0.02$ ) and triglycerides ( $1.9 \text{ mmol/L} \pm 0.9$  vs.  $2.4 \text{ mmol/L} \pm 2.9$ ,  $p=0.02$ ). Female gender reached borderline significance (chi-square=3.62,  $p=0.057$ ), and no differences were detected in other personal and disease-related variables. In multivariate analysis, gender (Wald  $\chi^2=3.84$ ,  $p=0.05$ ), education (Wald  $\chi^2=3.81$ ,  $p=0.05$ ) and BMI (Wald  $\chi^2=5.96$ ,  $p=0.01$ ) were shown to predict participation in treatment.

**Conclusion:** One-third (34%) of type 2 patients responded to postal screening for depression, 40% of them reporting elevated symptoms and a need for professional help. Two-thirds (68%) of eligible individuals were willing to enter treatment programmes. Women, better-educated persons and those with lower BMI were more likely to agree to participate in treatment programmes for subsyndromal depression.

### Effects of physical activity on quality of life, depressive symptoms and emotional well-being in type 2 diabetes mellitus: a systematic review

M.M.P. van der Heijden, F.E.P. van Dooren, V.J.M. Pop, F. Pouwer;  
Department of Medical Psychology and Neuropsychology, Tilburg University, Netherlands.

**Background and aims:** Achieving and/or maintaining an appropriate level of physical activity is an important goal in type 2 diabetes management, since physical inactivity is known to be one of the major risk factors for type 2 diabetes related complications. Systematic reviews and meta-analysis regarding the effects of physical activity in type 2 diabetes, so far mainly focused on biomedical outcomes. However, type 2 diabetes is also associated with psychological problems, concerning -but not limited to- depressive symptoms, decreased quality of life and decreased emotional well-being, which appear also to be related to the level of physical activity. The aim of this study is to conduct a systematic review in order to assess the effects of physical activity on depressive symptoms, quality of life and emotional well-being in type 2 diabetes patients.

**Materials and methods:** MEDLINE, PSYCHINFO, EMBASE and Clinicaltrials.gov databases were searched. The search comprised the terms type 2 diabetes mellitus, physical activity, randomized controlled trial, quality of life, depression, well-being, and related entry terms. Randomized controlled trials of at least 4 weeks' duration in type 2 diabetes patients, that evaluated the effect of a physical activity intervention on depressive symptoms and/or quality of life and/or emotional well-being compared to a control group with no or minimal intervention, were included. Risk of bias was assessed in accordance with the PRISMA statement.

**Results:** Of 1224 retrieved articles, 20 RCTs were included with a total of 1086 participants. 10 RCTs contained an aerobic activity, 5 RCTs a resistance activity and 10 RCTs a combined activity intervention. Intervention frequencies varied between 1x/week to 5x/week, session durations varied between 10 and 60 minutes. Program duration varied between 4 weeks and 6 months. Quality of life was assessed in 16 studies. Between group comparisons showed no significant results for aerobic activity and mixed results for resistance and combined interventions on quality of life. Depressive symptoms were assessed in 4 studies of which only one resistance intervention showed significant results. Emotional well-being was evaluated in 8 studies, also showing mixed results. Adequate random sequence generation was performed in 16 studies, adequate allocation concealment in 8 studies (unclear in 12 studies), blinding of outcome assessment was performed in 3 studies (unclear in 17 studies), losses and exclusions were adequately described in 16 studies and intention to treat analysis was performed in 5 studies (unclear in 7 studies).

**Conclusion:** Physical activity interventions that consist of resistance exercise or combined exercise may improve quality of life in patients with type 2 diabetes, although the results were mixed. Effects of physical activity interventions on depressive symptoms and emotional well-being are unclear. The large heterogeneity of the current interventions, heterogeneity of tests used to evaluate these psychological parameters and the limited number of studies evaluating depressive symptoms and well-being, limited the ability to draw conclusions. There is a need for higher quality RCTs evaluating the effect of physical activity interventions on psychological parameters in type 2 diabetes patients.

## OP 46 Foot ulceration: Can we do better?

### 253

#### Decreasing incidence of foot ulcers among patients with type 1 and type 2 diabetes

A. Rasmussen, T. Almdal, K.E. Nielsen, U.B. Christensen, A.A. Nielsen, P. Holstein;

Steno Diabetes Center, Gentofte, Denmark.

**Background and aims:** Foot ulcers are costly complication among diabetes patients. Figures of incidence of foot ulcers varies and there are only limited information in relation the change of incidence over time. The aim was to study the development in incidence of first foot ulcers in two large cohort of type 1 and type 2 diabetes followed for 10 years.

**Methods:** In Denmark all patients with type 1 diabetes (T1D) are followed lifelong in hospitals outpatients clinics, patients with type 2 diabetes (T2D) are only followed in hospitals clinics if they have advanced disease. Our clinic is a specialized diabetes clinic and is an integrated part of the public health care system. App 3500 patients with T1D and app 2000 patients with complicated T2D are followed. All patients are offered yearly feet inspection and education including determination of vibration threshold. Patients with high risk and/or abnormal vibration threshold ( $>40 \text{ mV}$ ) are seen by a chiropodist for instruction. When a foot ulcer is observed the patients is seen by the chiropodist immediately and if necessary a specialist in orthopedic surgery within at max 1 week. At the initial visit it is determined whether etiology of the ulcer is predominantly neuropathic or ischemic. All information in relation to the patients are housed in an electronic patient's record system. We determined the yearly incidence of the 1st registered foot ulcer among all T1D and T2D patients followed regularly in the clinic. Clinical characteristics of patients developing an incident foot ulcer in 2002 and 03 and 2010 and 11 are given.

**Results:** Changes in incidence over a 10 year period among patients with type 1 and type 2 diabetes appear in the figure. Among patients with T1D and first ulcers diagnosed in 2002 and 03,  $N=71$ , compare to those with first ulcer diagnosed in 2010 and 11,  $N=85$ , mean HbA1c were 9,2/8,8%, in T2D corresponding figures for 2002 and 03,  $N=135$ , and 2010 and 2011,  $N=92$ , mean HbA1c were 8,3%/8,3%. Proportion with diabetic retinopathy / microalbuminuria / macroalbuminuria in 2002 and 03 among in T1D patients were 72/29/28% and in 2010 and 11 62/ 39 /19%. The corresponding figures among T2D patients were 2002 and 03 58 / 32 / 21% and in 2010 and 2011 64/ 38 /15. Patients with T1D had a mean disease duration at time of first foot ulcer of 34,5 years in 2002 and 03 compared to 35 years in 2010 and 1. The corresponding figures for T2D patients were in 2002 and 03 15 years and in 2010 and 11 17 years.

**Conclusion:** The present study demonstrate that the incidence of 1 st foot ulcers have decreased in both patients with T1D and T2D, most pronounced in T2D. Patients developing ulcers have long disease duration and a high proportion of diabetes complications.

Incidence of first footulcer pr 100 patients pr patientyear

## 254

**Circulating pro-angiogenic cell number and growth factor profile may be altered in type 2 diabetes with/without diabetic foot syndrome**W.N. Nowak<sup>1</sup>, S. Borys<sup>2</sup>, K. Kusinska<sup>1</sup>, P. Witek<sup>2</sup>, T. Koblik<sup>2</sup>, A. Jozkowicz<sup>1</sup>, M. Malecki<sup>2</sup>, J. Dulak<sup>1</sup>;<sup>1</sup>Department of Medical Biotechnology, Jagiellonian University,<sup>2</sup>Department of Metabolic Diseases, Jagiellonian University Medical College, Krakow, Poland.

**Background and aims:** Type 2 diabetes mellitus (T2DM) is often complicated by diabetic foot syndrome (DFS). DFS pathogenesis may be associated not only with metabolic abnormalities, but also with alterations in stem and progenitor cell mobilization as well as with growth factor levels. It has been shown that both the functionality and the number of endothelial progenitor cells circulating in peripheral blood (PB) are altered in diabetic patients. However, some other stem cell populations potentially involved in wound healing and regeneration have never been examined in T2DM. Here, we analyze several populations of circulating proangiogenic progenitor cells (PACs) and growth factors in T2DM patients with/without different forms of DFS.

**Materials and methods:** We examined patients with four different forms of DFU: a) infected ulceration (DFU-I, n=10), b) non-infected ulceration (DFU, n=11), c) healed ulceration (DFU-H, n=6), and d) Charcot peripheral osteoneuropathy (ChPON, n=10). In addition, we included 17 healthy controls (H) and 10 T2DM patients without DFS. We used flow cytometry to evaluate the presence of the following stem cell populations based on their surface markers: CD45dimCD31+CD133+ and CD45dimCD31+CD34+KDR+ endothelial progenitor cells (EPCs), CD45-CD105+STRO-1+ and CD45-CD29+CD90+ mesenchymal stem cells (MSC), Lin-CD45+CD133+ hematopoietic stem cells (HSC), and Lin-CD45-CD133+ stem cells (SC). Furthermore, we evaluated serum levels of SCF, LIF, TPO, EGF, FGF-2, Flt3-L, G-CSF, TNF $\alpha$ , VEGF, SDF1 $\alpha$ + $\beta$  using Milliplex FlexMap 3D.

**Results:** Numbers of circulating CD45dimCD31+CD133+ were significantly decreased in diabetic patients without (but not with) foot ulceration (T2DM, ChPON) in comparison to healthy controls (T2DM: 584 $\pm$ 85, ChPON: 548 $\pm$ 64 vs. H: 872 $\pm$ 93 cells/1ml of peripheral blood,  $p < 0.05$ ). Similarly, the CD45-CD29+CD90+ MSC population was decreased in patients with T2DM and ChPON foot ulceration (T2DM: 47 $\pm$ 6, ChPON: 51 $\pm$ 18 vs. H: 156 $\pm$ 59 cells/1ml of PB,  $p < 0.05$ ). Number of circulating Lin-CD45-CD133+ SC was decreased ( $p < 0.001$ ) in DFU-I (10 $\pm$ 3 cells/1ml of PB) and ChPON (13 $\pm$ 5 cells/1ml of PB) groups in comparison to the T2DM group (39 $\pm$ 7 cells/1ml of PB). Patients with T2DM had significantly lower levels of serum EGF than healthy controls (T2DM 7.49 $\pm$ 2.16 vs. H: 81.10 $\pm$ 22.28, pg/ml  $p < 0.05$ ). Interestingly, the level of EGF in the group with healed foot ulcers (DFU-H: 93.45 $\pm$ 50.14 pg/ml) was comparable to that of healthy controls. Furthermore, the level of G-CSF was significantly higher in DFU (286.62 $\pm$ 63.65 pg/ml) than in the healthy group (77.15 $\pm$ 13.09 pg/ml;  $p < 0.05$ ).

**Conclusion:** Patients with T2DM and different forms of DFS have a decreased number of circulating pro-angiogenic progenitor cells. In addition, T2DM may be associated with a changed serum growth factor profile. Altogether, some of these factors can contribute to the pathogenesis of T2DM complications such as different forms of DFS.

## 255

**Relation between angiogenic cytokines and clinical effect of stem cell therapy in diabetic patients with no-option critical limb ischaemia**M. Dubsky<sup>1</sup>, A. Jirkovská<sup>1</sup>, L. Pagacová<sup>2</sup>, R. Bem<sup>1</sup>, V. Fejfarová<sup>1</sup>, B. Sixta<sup>3</sup>, V. Wosková<sup>1</sup>, J. Skibová<sup>1</sup>, S. Langkramer<sup>4</sup>, E. Sykova<sup>4</sup>;<sup>1</sup>Diabetes Centre, Institute for Clinical and Experimental Medicine,Prague, <sup>2</sup>Autotransfusion Unit, Institute for Clinical and ExperimentalMedicine, Prague, <sup>3</sup>Clinic of Transplant Surgery, Institute for Clinical and Experimental Medicine, <sup>4</sup>Institute of Experimental Medicine, Czech Academy of Science, Prague, Czech Republic.

**Background and aims:** The effect of angiogenic cytokines during the stem cell therapy is probably paracrine, but the exact role of serum levels of these cytokines in assessment of clinical effect and systemic vasculogenesis remains unclear. The release of pro-angiogenic cytokines such as vascular endothelial growth factor (VEGF), basic fibroblast growth factor (b-FGF), Angiopoietin-1 (Ang-1), Platelets-derived factors (PDGF-AA and PDGF-BB) and decrease of endogenous inhibitor of angiogenesis (Endostatin) can reflect both local and possibly systemic vasculogenesis after stem cell treatment. The aim

of our study was to assess the levels of angiogenic cytokines and their relation to clinical effect evaluated by changes of transcutaneous oxygen tension (TcPO<sub>2</sub>) in patients with diabetic foot ulcers (DFU) and no-option critical limb ischemia (NO-CLI).

**Materials and methods:** Systemic angiogenesis was evaluated by serum levels of VEGF, b-FGF, Ang-1, Endostatin, PDGF-AA and PDGF-BB after 1, 6 and 30 days from treatment and visualization was assessed by eye fundus examination before and 6 months after therapy. Clinical effect was evaluated by changes of TcPO<sub>2</sub> after 6 months. We included twenty five patients with NO-CLI (defined by TcPO<sub>2</sub> < 30 mm Hg) and DFU (mean age 61.9  $\pm$  9.9 years, mean diabetes duration 21.5  $\pm$  10.6 years) treated in our foot clinic from January 2008 to September 2011. Stem cell treatment was performed by two methods - bone marrow mononuclear cells (14 patients) or peripheral blood progenitor cells obtained by apheresis of peripheral blood stimulated by granulocyte-colony stimulating factor (11 patients). Cell suspension was concentrated, centrifuged and injected into the muscles of the affected limb.

**Results:** No significant correlation between clinical effect and levels of any of tested angiogenic cytokines was observed. Clinical effect measured by increase of TcPO<sub>2</sub> was significantly improved from 15.8  $\pm$  9.7 to 41.8  $\pm$  10.6 mmHg ( $p < 0.001$ ) after 6 months. We did not observe any significant increase of serum levels of pro-angiogenic cytokines in any of the follow-up control visits up to 30 days from procedure. PDGF-AA and PDGF-BB decreased significantly after 30 days ( $p = 0.034$  and  $p = 0.023$ , respectively). Levels of angiogenic inhibitor Endostatin increased significantly after 1 day ( $p = 0.029$ ) and 30 days ( $p = 0.0003$ ). No changes in eye fundus examination after 6 months from the treatment were seen.

**Conclusion:** Our study showed no relation between serum levels of angiogenic cytokines and clinical effect of stem cell therapy measured by TcPO<sub>2</sub>, but the effectiveness of this procedure was confirmed by significant increase of TcPO<sub>2</sub> in patients with NO-CLI. No increase of serum levels of pro-angiogenic cytokines during first month and no changes on eye fundus after 6 months may indicate safety of autologous stem cell treatment in terms of systemic angiogenesis.

## 256

**Does negative wound pressure therapy have a similar acute antimicrobial effect as maggot and ozone therapy on diabetic foot ulcer infection?**

R. Bem, A. Jirkovská, M. Dubsky, V. Fejfarová, V. Wosková, L. Rezaninová, J. Skibová;

Diabetes Centre, Institute for Clinical and Experimental Medicine, Prague, Czech Republic.

**Background and aims:** Previous studies showed that maggot debridement therapy (MDT) acutely eliminated most of the bacterial strains in patients with infected diabetic foot ulcers (DFU). Ozone is well known antimicrobial agent with broad-spectrum of medical indications. Negative wound pressure therapy (NWPT) was also reported as a useful method, which may improve infection resolution and wound healing. The aim of our study was to compare the acute antimicrobial effect of ozone therapy, MDT and NWPT with standard local therapy in patients with infected DFU.

**Materials and methods:** 120 patients with infected DFU (Texas 2-3; B and D) hospitalized in our Diabetes Department were enrolled in the present study between January 2010 and February 2012. All patients were treated with parenteral antibiotics appropriate to microbial findings and standard therapy (offloading, surgical intervention, etc.). In addition to standard treatment, 30 patients were treated by gaseous ozone once daily (ozone group), 30 patients by sterile free-range larvae of the green bottle fly *Lucilia sericata* (MDT group) and 30 patients by NWPT (NWPT group). 30 patients received standard local treatment, mainly disinfectant solutions (Controls). There was no significant difference between groups in age, gender, type and duration of diabetes, diabetes control, C-reactive protein, Texas score and presence of osteomyelitis. Swabs or tissue specimens for culture were taken from deep structures of the wound after debridement immediately before and after intervention or in comparable time in Controls. Groups did not differ in the mean therapy duration (ozone 3.3 $\pm$ 1 vs. maggots 3.6 $\pm$ 0.7 vs. NWPT - first dressing 3.4 $\pm$ 0.7 vs. Controls 3.8 $\pm$ 0.6 days; NS). The individual bacterial species in positive swabs were determined by standard microbiological methods.

**Results:** There were no significant differences between groups in the numbers of bacteria strains per specimen before treatment. After the treatment, significant reductions in the numbers of bacteria strains in ozone group (before 2.3 $\pm$ 1.1 vs. after 0.7 $\pm$ 0.7;  $p < 0.0001$ ), in MDT group (2.6 $\pm$ 0.9 vs. 0.7 $\pm$ 0.5;  $p < 0.0001$ ) and in NWPT group (2.2 $\pm$ 0.9 vs. 1.1 $\pm$ 0.9;  $p < 0.0001$ ) were seen, but

there was no significant reduction in Controls ( $2.2 \pm 0.9$  vs.  $1.9 \pm 0.6$ ). All study methods significantly reduced the number of bacteria strains in comparison with Controls (all  $p < 0.01$ ). NWPT reduced the number of bacteria strains significantly less than maggots ( $p < 0.01$ ) and ozone ( $p < 0.05$ ). Ozone was effective especially against *Enterococcus* and *Staphylococcus* sp. (both  $p < 0.05$ ), MDT against *Enterococcus* sp., *Escherichia coli* and *Proteus* sp. (all  $p < 0.05$ ) and NWPT against *Streptococcus* sp. ( $p < 0.05$ ).

**Conclusion:** Our study demonstrated that both ozone therapy or MDT and NWPT added to standard treatment may help influence polymicrobial infection in the DFU in comparison with standard local therapy. NWPT was slightly less effective than both maggot and ozone therapy.

## OP 47 Tuning into the rhythm of clock genes in diabetes

257

**The effects of adiponectin on free-running locomotor activity rhythm and circadian expression of core clock genes in model mice for metabolic syndrome**

K. Yamada, T. Hashinaga, N. Wada, S. Otabe, H. Nakayama, Y. Tajiri; Endocrinology and Metabolism, Kurume University, Japan.

**Background and aims:** Alterations of circadian rhythms through genetic and environmental influences on the molecular clock are pivotal in the pathogenesis of obesity, type 2 diabetes and cardiovascular disease. The disturbed circadian rhythm in obese subjects can be restored at least partly by weight loss with low-calorie diet or bariatric surgery. However, the mechanism by which excess adipose tissue accumulation affects circadian clock is still largely unknown. In this study we assessed the effect of adiponectin on the circadian rhythm disturbances associated with metabolic syndrome using adiponectin-transgenic mice.

**Materials and methods:** We generated a KK/Ta mouse line expressing the human adiponectin transgene in the liver. Although KK/Ta mice had hypoadiponectinemia, serum adiponectin levels of transgenic KK/Ta mice were higher than those of control C57BL/6 mice. Spontaneous locomotor activity under 12-h light/12-h darkness cycle and free-running rhythm under constant darkness were analyzed using digital counters. The expression of core clock genes was measured by quantitative real-time RT-PCR.

**Results:** Locomotor activity of C57BL/6 mice was highest during the beginning of the dark period and low during the light period. Under constant darkness, the length of locomotor activity rhythm of control mice was slightly shorter than 24 h. In KK/Ta mice the peak of locomotor activity was blunted and significant activity was observed during the light period. Furthermore, KK/Ta mice showed shorter average period length of free-running locomotor activity rhythm. However, the transgenic expression of adiponectin in the liver significantly restored the circadian rhythm of locomotor activity and the length of free-running rhythm of KK/Ta mice. In the liver and skeletal muscles from control mice, mRNA levels of *Arntl* and *Cry1* were increased during the dark period, whereas those of *Dbp*, *Cry2*, *Per1* and *Per2* were elevated during the light period. KK/Ta mice exhibited phase advances in circadian rhythms of *Arntl*, *Dbp*, *Cry2* and *Per2* in both tissues. The phase shifts in the liver were corrected in adiponectin-transgenic mice.

**Conclusion:** The restoration of circadian rhythm was not attributable to weight loss, because there was no significant difference in body weight between KK/Ta mice and adiponectin-transgenic KK/Ta mice. Adiponectin has two different signaling pathways: one mediated by peroxisome proliferator-activated receptor- $\alpha$  (PPAR- $\alpha$ ) and the other mediated by 5'-AMP-activated protein kinase (AMPK). PPAR- $\alpha$  has been shown to bind to the *Arntl* promoter and up-regulate its expression. On the other hand, AMPK phosphorylates and destabilizes *Cry1*. Furthermore, adiponectin down-regulates TNF- $\alpha$ , which suppresses several clock genes in the liver. Although further studies were required to elucidate the detailed molecular mechanism by which adiponectin modified circadian rhythm of the metabolic syndrome model animal, adiponectin may be a peripheral regulator of the circadian clocks in the brain and peripheral organs, and may be a novel target for the treatment of obesity-associated disorders of circadian rhythms.

258

**Diabetic complications and circadian rest-activity rhythmicity**

M. Kadono, G. Hasegawa, T. Sennmaru, N. Nakamura; Endocrinology and Metabolism, Kyoto Prefectural University of Medicine, Japan.

**Background:** Emerging evidence from a variety of studies indicates that circadian rhythmicity is associated with aging process. Diabetes is considered to be a premature aging process. In particular, diabetic complications, neuropathy and angiopathy, are critical factors for the disease prognosis, accelerating patients' physical aging. Therefore, it is possible that the progression of these complications could involve disruption of circadian rhythmicity. In this study, we investigated the association between actigraphic estimates of the rest-activity rhythm and diabetic complications.

**Materials and methods:** Seventy-two outpatients in our diabetes clinic wore an actigraph for consecutive 7 days (men /women 30/42, age  $68.5 \pm 8.2$

yrs, BMI<25kg/m<sup>2</sup>, type2/type1 diabetes 69/3). Patients with depression, dementia, liver cirrhosis, renal failure, blindness, and shift work were excluded. Activity profiles were analyzed using nonparametric variables, including dichotomy indices, interdaily stability (IS), intradaily variability (IV), relative circadian amplitude (RA), nocturnal awakening (fNA (22:00–1:00), INA (1:00–4:00)), and morning activities (MoA). To cluster diabetic clinical characteristics and determine the clusters predicting circadian rhythms disruption, principal factor analysis (PFA) was applied.

**Results:** BMI was positively correlated with IV and INA ( $P=0.006$  and  $.004$ ), and negatively correlated with IS and RA ( $P=0.007$  and  $=0.008$ ), while diabetic duration was associated with IS ( $P=0.01$ ). Patients with progressive diabetic retinopathy had significantly lower RA, compared to those without retinopathy ( $p=0.02$ ). Patients with symptomatic neuropathy had significantly lower IS, higher fNA, and lower MoA ( $P=0.02$ ,  $.03$ , and  $.02$ , respectively). The levels of urinary albumin excretion were positively correlated with IV and INA ( $P=0.005$  and  $=0.004$ ), and negatively correlated with IS and RA ( $P=0.004$  and  $=0.003$ ). The significance remained after adjusting for BMI. Next, PFA identified two factors that explained 24 and 14 % of the variance in the variance in the dataset of diabetic clinical characteristics, respectively. These factors were interpreted as 1) a “duration” factor (DF) with positive loadings of diabetic duration, tripathic parameters, and the history of cardiovascular diseases, and 2) a “metabolic” factor (MF) with positive loadings of BMI, HbA<sub>1c</sub>, TG, and HDL. Multivariate analysis with a model including DF and MF showed that both factors were independent predictors of IV ( $p=0.04$ , and  $.04$ ), and of IS ( $p=0.02$ , and  $.006$ ).

**Conclusion:** Diabetic complications, angiopathy and neuropathy, were associated with disruption of circadian rest–active rhythm. The current results indicate a key common regulator of circadian rhythms and neurovascular function. In addition, metabolic factors and duration factors were independently associated with disruption of circadian rest–activity rhythms. It can be speculated that lifestyles with irregular circadian rhythmicity will cause difficulty metabolic control including weight and daily blood sugar control, and thus hasten the development of these complications, resulting in a vicious cycle. Taken together, chronobiological approach, especially, circadian rhythms entrainment should be considered as a possible therapy for diabetes.

## 259

### Robust circadian clocks are ticking in beta and non-beta cells of human pancreatic islets

C. Dibner<sup>1</sup>, T. Mannic<sup>1</sup>, D. Sage<sup>2</sup>, S. Lemeille<sup>1</sup>, D. Bosco<sup>1,3</sup>, P. Salmon<sup>3</sup>, C. Bauer<sup>3,2</sup>, M. Unser<sup>2</sup>, P. Halban<sup>3</sup>, J. Philippe<sup>1</sup>

<sup>1</sup>Endocrinology, Diabetes and Nutrition, University Hospital of Geneva,

<sup>2</sup>EPFL, Lausanne, <sup>3</sup>University of Geneva, Switzerland.

**Background and aims:** Due to the emerging evidence of the pancreas clock impact on the islet function and on type 2 diabetes development as shown in rodents, we aimed to tackle the circadian clockwork in human islets. The oscillator properties were assessed in the intact islets, and as well as in  $\beta$ -cells.

**Materials and methods:** We established a system for long term bioluminescence recording in cultured human islets, employing lentivector gene delivery.  $\beta$ -cells were stably labeled by rat insulin2 promoter (RIP) fluorescent construct. Single islet/ cell oscillation profiles were measured by combined bioluminescence - fluorescence time lapse microscopy.

**Results:** Human islets exhibited robust self-sustained circadian oscillations of *Bmal1-luciferase* expression at the both populations and single islet levels, with the oscillation period of 23.6 and 23.9 hours respectively. Moreover, endogenous *Bmal1* transcript expression was circadian in synchronized islets over 48 hours, and antiphasic to *Reverba*, *Per2* and *Dbp* transcript circadian profiles. Importantly, single  $\beta$ - and non- $\beta$  cells revealed oscillatory profiles well synchronized with each other.

**Conclusion:** We provide for the first time a compelling evidence for a robust cell autonomous clock ticking in human islets. Moreover,  $\beta$ -cells possess their own clocks oscillating in synchrony with non- $\beta$ -cells in primary human islet cell culture.

### An isocaloric high fat diet modulates daily expression profiles of clock genes, LPS response and fat metabolism genes in human monocytes

O. Pivovaro<sup>1,2</sup>, S. Hornemann<sup>1,2</sup>, L. Ye<sup>1,2</sup>, S. Möckel<sup>1</sup>, M. Kruse<sup>1,2</sup>, J. Mazuch<sup>3</sup>, A. Kramer<sup>3</sup>, A. Busjahn<sup>4</sup>, A.F.H. Pfeiffer<sup>1,2</sup>

<sup>1</sup>Department of Clinical Nutrition, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, <sup>2</sup>Department of Endocrinology, Diabetes and Nutrition, Campus Benjamin Franklin, Charité University Medicine, Berlin, <sup>3</sup>Laboratory of Chronobiology, Institute for Medical Immunology, Charité University Medicine, Berlin, <sup>4</sup>HealthTwist GmbH, Berlin, Germany.

**Background and aims:** The circadian clock coordinates various behavioural and physiological processes including feeding, energy metabolism and inflammation response. In turn, metabolic processes feed back onto the circadian clock as shown in recent human and animal studies. However, there is little to no information about the effect of nutrition on circadian mechanisms in humans. To address this, we provided the analysis of daily expression profiles of clock genes, LPS response and fat metabolism genes in human blood monocytes before and after the high-fat diet intervention.

**Materials and methods:** Daily gene expression profiles were determined by real-time PCR in 30 non obese healthy individuals in terms of NUTriGenomics Analysis in Twins (NUGAT) study. Gene expression was measured at three time points (in the morning, in the middle of the day and afternoon) during three investigation days. The blood sampling was carried out before the beginning of the high-fat isocaloric diet (HFD, 45 % kcal from fat) and after one and six weeks of intervention.

**Results:** We demonstrated that clock genes (*PER1*, *PER2*, *PER3*, *BMAL1*, *REV-ERB $\alpha$* , *DBP* and *TEF*) as well as genes contributing to LPS response (*CD14*, *IKB $\alpha$* , *CD180*, *ERK1*, *IL1 $\beta$* , *IL10*, *TNF $\alpha$* , *CCl3*) and fat metabolism (*FASN*, *CPT1a*) exhibited significant daily variation in human monocytes. The HFD induced the increase of the expression of the *Period* genes *PER1*, *PER2* and *PER3* and *TEF* after one and six weeks of intervention ( $p<0.05$ ) and alterations of synchronisation state within clock gene system. Moreover, the HFD effected the expression of LPS response genes *CD14*, *IKB $\alpha$*  and *IL8* and fat metabolism genes *ACOX3* and *IDH3A*. Furthermore, the expression levels of *Period* genes and *TEF* significantly correlated with blood cholesterol levels and with the *ACOX3* and *IDH3A* expression in monocytes.

**Conclusion:** Our results suggest that the consumption of an isocaloric HFD can influence the circadian clock as well as circadian expression of genes contributing to LPS response and fat metabolism in humans already after the short time intervention. This emphasizes the role of nutrition-clock interaction in the regulation of human metabolism and inflammation response.

## OP 48 Imaging beta cell mass in vivo

### 261

**In vivo imaging of beta cell mass by [<sup>11</sup>C]5-hydroxy-tryptophan PET**  
**O. Eriksson**<sup>1</sup>, D. Espes<sup>2</sup>, R. Selvaraju<sup>1</sup>, J. Sörensen<sup>3</sup>, M. Lubberink<sup>3</sup>, G. Antoni<sup>3</sup>, L.A. Johansson<sup>3,4</sup>, J. Eriksson<sup>4</sup>, P.-O. Carlsson<sup>2,5</sup>, B. Eriksson<sup>5</sup>, O. Korsgren<sup>6</sup>;  
<sup>1</sup>Preclinical PET Platform, Uppsala, <sup>2</sup>Dept. of Medical Cell Biology, Uppsala, <sup>3</sup>Department of Radiology, Oncology and Radiation Sciences, Uppsala, <sup>4</sup>AstraZeneca, Mölndal, <sup>5</sup>Dept. of Medical Sciences, Uppsala, <sup>6</sup>Dept. of Immunology, Genetics and Pathology, Uppsala, Sweden.

**Background and aims:** The ability to undertake repeated non-invasive monitoring of pancreatic beta cell mass (BCM) in subjects with T1D and T2D would be of immense importance. The PET tracer [<sup>11</sup>C]5-hydroxy-tryptophan ([<sup>11</sup>C]5-HTP) rapidly accumulates in cells using serotonin. As serotonin is present in beta cells, but not in exocrine pancreas, we hypothesized that [<sup>11</sup>C]5-HTP could be used as a biomarker for BCM.

**Materials and methods:** Islet specificity of [<sup>11</sup>C]5-HTP was assessed by IHC staining for serotonin on pancreatic sections from T1D and healthy controls, and by incubation of human islet cell preparations. Control and STZ-treated rats were administered [<sup>11</sup>C]5-HTP and the pancreatic uptake was determined by organ distribution. In vivo specificity was assessed in a non-human primate model. Pancreatic uptake was investigated in healthy controls and subjects with T1D or T2D in clinical studies.

**Results:** IHC staining showed co-localization of serotonin with insulin in healthy pancreas, and serotonin positivity diminished in parallel with insulin in T1D. Incubation of isolated human islets mixed in different ratios with exocrine cells showed strong positive linear correlation ( $R^2 > 0.9$ ,  $p < 0.05$ ) between islet purity and [<sup>11</sup>C]5-HTP uptake. Pancreatic uptake in diabetic rats was decreased (Standard Uptake Value; SUV  $2.6 \pm 0.4$ ,  $p < 0.05$ ) compared to non-diabetic controls (SUV  $5.0 \pm 0.2$ ), and correlated to decrease in beta cell mass as assessed by IHC. PET/CT of non-human primates showed that 80% of the pancreatic uptake was dependent on the serotonin biosynthesis pathway as it could be inhibited by iv administration of carbidopa. Retrospective data in non-diabetic patients showed a distinct pancreatic uptake (SUV  $= 2.9 \pm 0.4$ ), while uptake in two T2D patients was decreased by 33 and 56%, respectively. In one of the patients, repeated [<sup>11</sup>C]5-HTP PET measurements showed gradual reduction in parallel with the progression of T2D from diagnosis to insulin requirement. An ongoing prospective [<sup>11</sup>C]5-HTP PET study demonstrated accumulation of tracer in pancreas of controls ( $n=3$ ), whereas tracer uptake in the pancreas of T1D patients ( $n=2$ ) decreased towards background within 60 min (figure).

**Conclusion:** We show both experimental and clinical results demonstrating the feasibility of [<sup>11</sup>C]5-HTP PET as novel method for quantifying human BCM, allowing monitoring of disease progression as well as evaluation of new therapies.

**Fig.** Distinct uptake of [<sup>11</sup>C]5-HTP in the pancreas of a healthy subject (pancreas in origo; left panel), whereas low uptake is seen in the pancreas of a c-peptide negative T1D patient (right panel). Tracer excreted into urine causes the kidney signal.

**Multimodality non-invasive imaging of the functional beta cell mass using various formats of the beta cell surface specific monoclonal autoantibody IC2**

**C.-H. Brogren**<sup>1</sup>, I.D. Pedersen<sup>1</sup>, K.L. Jensen<sup>1</sup>, A. Briat<sup>2</sup>, L. Bronsart<sup>3</sup>, M.H. Bachmann<sup>3</sup>, L. Renaut<sup>4</sup>, P. Mondon<sup>4</sup>, W. Petersen<sup>5</sup>, S. Manohar<sup>5</sup>, B. Hesse<sup>6</sup>, A. Kjær<sup>6</sup>, K. Buschard<sup>1</sup>, D. Christiaen<sup>2</sup>, C.H. Contag<sup>3</sup>;  
<sup>1</sup>The Bartholin Institute, Rigshospitalet, Copenhagen, Denmark, <sup>2</sup>Animascope, Grenoble, France, <sup>3</sup>Molecular Biophotonics and Imaging Laboratory, Stanford School of Medicine, Palo Alto, USA, <sup>4</sup>Millegen, Toulouse, France, <sup>5</sup>University of Twente, Enschede, Netherlands, <sup>6</sup>Department of Biomedical Sciences, University of Copenhagen, Denmark.

**Background and aims:** For more than a decade multiple tracers have been used in an attempt to quantitatively and specifically image the  $\beta$ -cell mass (BCM) in vivo. However, none of the drugs and only one of the antibody based tracers applied have shown sufficient specificity and affinity, which is the rat monoclonal autoantibody IC2. This autoantibody raised from a newly diabetic BB-rat has been shown to have a unique specificity for the surface of insulin secreting pancreatic  $\beta$ -cells from multiple animal species and humans. The autoantibody has no diabetogenic or cytotoxic effects in vivo. The first in vivo attempt as biomarker for BCM, but not fully noninvasive, was done by SPECT and <sup>111</sup>In-labelled IC2-IgM. However such a large IgM tracer molecule will not easily be excreted if in excess, so attempts have been made to use either the pepsin fragments F(ab')<sub>2</sub> and Fab, or alternatively recombinant and chimeric formats, which in size span from 50–150 kDa, to enable a faster excretion. The pancreas is high vascularised, which ensure a fast and easy delivery of all tracers formats to targeted islets.

**Materials and methods:** First fully noninvasive imaging trials were done on rats with a 2-head SPECT and <sup>111</sup>In-labelled IC2 as tracer, which were followed up by both rat and mice biodistribution studies using <sup>125</sup>I Iodogen-labeled IC2-IgM, F(ab')<sub>2</sub>, and Fab, two other monoclonal antibodies, K14D10, A2B5, and a rat isotype IgM control. Our second imaging modality uses Gaussian luciferase-IC2-diabody format in noninvasive BLI on mice. The third modality applies gold nanorods labeled with IC2 in animal photoacoustic imaging, and our fourth modality will be near-infrared fluorescence-mediated tomography using Vivotag-680nm and VivoTag-750nm labeled pepsin fragments of F(ab')<sub>2</sub> and Fab plus a newly engineered recombinant chimeric rIC2-hIgG1 format applied in mice BCM imaging.

**Results:** The first fully proof-of-concept for in vivo BCM-imaging was obtained with a Gaussian luciferase linked diabody fusion protein in mouse bioluminescent imaging (BLI). The pancreatic homing and specificity was further confirmed by rat and mice biodistribution studies with radioiodinated IC2, F(ab')<sub>2</sub> and Fab fragments. Recently we have transferred these into formats for NIR noninvasive imaging. Fluorescence-mediated tomography (FMT-NIR) gives the second proof-of-concepts for animal BCM noninvasive imaging using the unique functional beta-cell specificity of IC2.

**Conclusion:** It seems likely to conclude, that IC2 fragments or chimeric engineered formats with an appropriate size potentially could be applied in clinical noninvasive imaging of functional BCM, either with SPECT or PET. Our fifth modality forward in our preclinical trials will be a 4-head NanoSPECT-CT to explore the new chimeric rIC2-hIgG1 and diabody formats further as clinical tracers. The ultimate goal is a full clinical method used for diabetes diagnostic, to follow effects of beta-cell growth promoting drugs, in stem-cell therapy and in islet transplantation.

**Longitudinal imaging of transplanted islets in a rat model with SPECT**  
**K.M. Andralojc**, M. Brom, L. Joosten, D.L. Bos, W.J.G. Oyen, O.C. Boerman, M. Gotthardt;  
 Department of Nuclear Medicine, Radboud University Nijmegen Medical Center, Netherlands.

**Aim:** Pancreatic islet transplantation is a promising clinical modality to restore normoglycemia in diabetic patients. However, patients still experience an islet loss immediately after transplantation as well as on the long term. Therefore, there is an urgent need for a method that would non-invasively monitor beta cell mass (BCM) after transplantation *in vivo*. Such a method could give more insight into rejection and could aid to further improve treatment of diabetic patients. We have developed a non-invasive imaging technique that specifically visualizes beta cells *in vivo*. This method is based

on targeting the glucagon-like peptide1 receptor (GLP-1R). The GLP-1R is expressed at high levels on pancreatic beta cells. Our radiolabelled tracer, In-111-labeled Exendin-3, specifically binds to the GLP-1R. We examined whether intramuscularly transplanted islets in rats could be visualized by microSPECT after i.v. injection with radiolabeled Exendin-3.

**Materials & methods:** Islets of Langerhans were isolated from Wag/Rij rats. Various numbers of islets (25–1000) were transplanted into the left thigh muscle of Wag/Rij rats ( $n=20$ ), while vehicle was injected in the right muscle as a control. Rats were monitored up to 14 weeks post-transplantation. SPECT was performed every 1–2 weeks, one hour after i.v. injection of In-111-labeled Exendin-3, using a U-SPECT II microSPECT scanner. After acquiring the last SPECT, the rats were euthanized and the radioactivity in the transplant and other relevant tissues was measured. The muscle with engrafted islets was embedded in paraffin for microautoradiography and immunohistochemistry.

**Results:** The transplanted islets were clearly visualized with SPECT (Fig. 1) at every time-point. Images could be analysed quantitatively. Transplantation of varying numbers of islets revealed an excellent, linear correlation between the SPECT signal and the number of transplanted islets (Pearson  $r=0.99$ ). In rat model, the high sensitivity of the method allowed reliable longitudinal monitoring of the graft during at least 3 months. *Ex vivo* microautoradiography and immunohistochemistry of anti-insulin and anti-GLP-1R staining performed on consecutive histological slices showed high accumulation of In-111-exendin-3 in the beta cells. Anti-insulin staining confirmed that islets after transplantation were viable and produced insulin.

**Conclusion:** In-111-exendin-3 accumulated efficiently in transplanted islets after i.v. injection and targeted insulin producing beta cells via GLP-1 receptor. Transplanted islets could be clearly delineated by microSPECT, allowing long time follow-up. The method is sensitive (25 islets could be visualized) and quantitative as radioactivity in the grafts correlated linearly with the number of transplanted islets. This novel method is reliable, reproducible and robust and holds great potential for non-invasive monitoring of BCM after transplantation in humans.

**Figure 1** 3D volume rendering display of a SPECT/CT of 1,000 islets transplanted in the left hind leg, acquired 1 hour after injection of 15 MBq of In-111-exendin-3 (red arrow indicates 1,000 islets). SPECT/CT was performed 4 weeks post transplantation.

### Quantitative assessment of vascular remodelling in a subcutaneous site following islet transplantation

R. Storrs<sup>1</sup>, R. Krishnan<sup>2</sup>, R. Arora<sup>2</sup>, H. Dogar<sup>2</sup>, M. Lamb<sup>2</sup>, S. White<sup>3</sup>, C. Foster III<sup>2</sup>, E. Botvinick<sup>3</sup>, B. Choi<sup>3</sup>, J.R. Lakey<sup>2</sup>

<sup>1</sup>Islet Sheet Medical LLC, San Francisco, <sup>2</sup>Surgery, University Of California, Irvine, Orange, <sup>3</sup>Beckman Laser Institute and Medical Clinic, University Of California, Irvine, Irvine, USA.

**Background and aims:** Islet transplantation is hampered by a scarcity of human islet donors, inconsistent islet yields and poor function, a problem which may be addressed by xenotransplantation. Islet xenografts require prolonged immunosuppression or biomaterial encapsulation to evade immune-mediated destruction. Although prolonged islet survival with encapsulation has been documented, insufficient oxygen delivery results in suboptimal islet function. Existing models cannot evaluate and quantify the vascular remod-

elling that occurs in response to subcutaneous biomaterial implantation and islet transplantation, non-invasively. We address this problem by employing the mouse dorsal window-chamber model (DWM), Laser Speckle Imaging (LSI) and analyzed changes in subcutaneous functional vascular density (FVD) longitudinally post transplantation.

**Materials and methods:** DWMs were implanted in C57BL/6 albino mice. Host vascular response to introduction of a high guluronate alginate sheet with or without islets (porcine and syngeneic murine) encapsulated within (Fig. 1), was studied over a 7-day period. LSI was performed on days 0 and 7 to map changes in blood flow within. The images obtained were analyzed to evaluate changes in functional vascular density.

**Results:** Vasodilatation and arteriovenous connection formation (Fig. 1D), an increase in the relative rate of blood flow (Fig. 1E) and an increase in the density of functioning capillaries is noted by day 7 (Fig. 1H). The increase in Functional Vascular Density was 45.03%, 43.73% and 65.86% in blank sheets (from  $3.1 \pm 0.11$  to  $4.5 \pm 0.2$ ), sheets containing pig Islets (from  $3.8 \pm 0.15$  to  $5.5 \pm 0.25$ ) and sheets containing mouse Islets (from  $2.7 \pm 0.17$  to  $4.4 \pm 0.13$ ) respectively. The rate of change of Functional Vascular Density is higher in windows containing islet implants ( $1.70 \pm 0.04$ ) as compared to blank sheets ( $1.41$ ).

**Conclusion:** We postulate that all these findings suggest that biomaterial implants can induce angiogenesis which is expected to redound favorably on islet survival. Future experiments will attempt to correlate these findings with islet viability and function as well as extending post transplantation monitoring.

**Fig. 1** DWM Implanted with an alginate sheet containing porcine islets. Lateral view (A). Schematic (B) Bright field Microscopy: Days 0 (C) & 7 (D). LSI performed at 100 ms exposure was used to construct Speckle Flow Index Maps (Day 0) & (Day 7) and Speckle Contrast Maps (not shown). The latter were processed to get Functional Vascular Density Maps (Days 0 (G) & 7 (H)). Black arrows indicate increased blood flow. White arrow heads denotes the islets encapsulated within the sheet.

#### Vitamin D intake during childhood and advanced beta cell autoimmunity in young children with HLA-conferred susceptibility to type 1 diabetes

S.M. Virtanen<sup>1,2</sup>, H.-M. Takkinen<sup>2</sup>, L. Uusitalo<sup>1,2</sup>, S. Niinistö<sup>1</sup>, S. Ahonen<sup>2</sup>, J. Nevalainen<sup>3</sup>, M.G. Kenward<sup>4</sup>, R. Veijola<sup>5</sup>, J. Ilonen<sup>6,7</sup>, O. Simell<sup>8</sup>, M. Knip<sup>9,10</sup>,  
<sup>1</sup>Life Style and Participation, National Institute for Health and Welfare, Helsinki, <sup>2</sup>School of Health Sciences, University of Tampere, <sup>3</sup>Social Research, Statistics, University of Turku, Finland, <sup>4</sup>Epidemiology and Population Health, London School of Hygiene and Tropical Medicine, London, UK, <sup>5</sup>Pediatrics, University of Oulu, <sup>6</sup>Virology, University of Eastern Finland, Kuopio, <sup>7</sup>Virology, University of Turku, <sup>8</sup>Pediatrics, University of Turku, <sup>9</sup>the Children's Hospital, University of Helsinki, <sup>10</sup>Pediatrics, University Hospital of Tampere, Finland.

**Background:** Evidence for the role of vitamin D during childhood in the development of beta-cell autoimmunity and clinical diabetes is inconsistent.

**Materials and methods:** Two hundred seventy-four children with repeated positivity for antibodies against islet cells (ICA), together with positivity for at least one of the other three antibodies analyzed or clinical type 1 diabetes (a composite endpoint of advanced beta-cell autoimmunity) were identified from a prospective birth cohort of 7787 infants with HLA-DQB1-conferred susceptibility to type 1 diabetes born in 1996–2004. Three-day food records were completed by the families and day care personnel at 3 to 12 month intervals. Four birth date, gender, area and genetic risk matched controls having been in the follow-up at least until the age when the case became a case were randomly selected for each case.

**Results:** The mean dietary intakes of vitamin D from diet and supplements for 3 and 6 month, 1, 2, 3, 4 and 6 year-olds were 10.4, 12.1, 11.1, 7.9, 5.9, 5.1 and 6.3 µg/day, respectively. Vitamin D intake either from food (OR 1.08, 95% CI 0.97–1.20), supplements (OR 0.96, 95% CI 0.86–1.07) or the total dietary intake (OR 0.96, 95% CI 0.83–1.11) were not associated with advanced beta-cell autoimmunity.

**Conclusion:** In relation to the nutrition recommendations the average intake of vitamin D was suboptimal among these children with HLA-conferred susceptibility to type 1 diabetes. The longitudinal vitamin D intake was not, however, related to the development of advanced beta-cell autoimmunity.

#### Serum levels of soluble receptors for advanced glycation end products decline at seroconversion to autoantibody positivity in prediabetic children

K.M. Salonen<sup>1</sup>, S. Ryhänen<sup>1</sup>, J.M. Forbes<sup>2</sup>, J. Ilonen<sup>3,4</sup>, P.-H. Groop<sup>5,6</sup>, M. Knip<sup>1,5</sup>;

<sup>1</sup>Children's Hospital, University of Helsinki and Helsinki University Hospital, Finland, <sup>2</sup>Baker IDI Heart & Diabetes Institute, Melbourne, Australia, <sup>3</sup>Immunogenetics Laboratory, University of Turku, <sup>4</sup>Department of Clinical Microbiology, University of Eastern Finland, Kuopio, <sup>5</sup>Folkhälsan Research Center, Helsinki, <sup>6</sup>Department of Nephrology, Department of Medicine Helsinki University Central Hospital, Biomedicum Helsinki, Finland.

**Background and aims:** The receptor for advanced glycation end products (RAGE) is a multiligand receptor involved in inflammatory and immune responses. RAGE is suggested to play a role both in the pathogenesis of type 1 diabetes (T1D) and in the development of its complications. The circulating concentrations of soluble RAGE (sRAGE) may be reduced during acute autoimmune processes. This study set out to assess the dynamics of sRAGE during the preclinical T1D disease process.

**Materials and methods:** Serum levels of sRAGE were analyzed in 110 children who progressed to T1D during prospective observation. Samples analyzed were taken at four different time points: (1) before seroconversion to autoantibody positivity; (2) at the time of seroconversion to positivity for one autoantibody; (3) at the time of seroconversion to positivity for multiple ( $\geq 2$ ) autoantibodies; and (4) close to the diagnosis of T1D. Samples of 110 autoantibody-negative controls matched for age, sex, HLA-genotype and place of birth were analyzed for sRAGE at corresponding time points.

**Results:** The progressors had higher levels of sRAGE at all four time points, but the difference was significant only in the first and last sample [mean difference 172 pg/ml,  $p=0.01$  and 164 pg/ml,  $p=0.02$ , respectively (t-test)]. There was a decline in the sRAGE levels in the progressors between the first sample and the second sample [mean sRAGE 1400 pg/ml vs. 1251 pg/ml,  $p=0.001$  (paired t-test)]. A difference in the sRAGE concentrations was also seen when the first sample was compared to the third sample (mean sRAGE 1402 pg/ml vs. 1232 pg/ml,  $p<0.001$ ). There was no such difference in sRAGE levels between the samples taken from the matched controls at corresponding time points. There were no significant differences between the sRAGE levels at seroconversion and the concentrations at T1D diagnosis.

**Conclusion:** Prediabetic children seem to have higher circulating concentrations of sRAGE when compared to controls. A reduction in the circulating sRAGE concentrations coincides with the appearance of diabetes-predictive autoantibodies in children progressing to overt T1D. Whether this reflects a damaging or attempted protective mechanism remains to be defined.

### 267

#### Screening for IA-2 and zinc transporter 8 antibodies identifies relatives of type 1 diabetic patients with a high and age-independent progression rate to clinical onset

E.V. Balti<sup>1</sup>, S. Demeester<sup>1</sup>, A. Van Dalem<sup>1</sup>, O. Costa<sup>1,2</sup>, H. Dorchy<sup>3</sup>, S. Tenoutasse<sup>3</sup>, T. Mouraux<sup>3,4</sup>, C. De Block<sup>5</sup>, P. Gillard<sup>6</sup>, K. Decocchez<sup>1,7</sup>, J.M. Wenzlau<sup>8</sup>, J.C. Hutton<sup>8</sup>, D.G. Pipeleers<sup>1</sup>, I. Weets<sup>1,2</sup>, F.K. Gorus<sup>1,2</sup>;  
<sup>1</sup>Diabetes Research Center, Brussels Free University, <sup>2</sup>Department of Clinical Chemistry and Radio-immunology, University Hospital Brussels, <sup>3</sup>Diabetology Clinic, Queen Fabiola Children's University Hospital, Brussels, <sup>4</sup>Department of Pediatrics, University Hospital Mont-Godinne, Yvoir, <sup>5</sup>Department of Endocrinology, Diabetology and Metabolism, University of Antwerp, <sup>6</sup>Department of Endocrinology, University Hospital Leuven, <sup>7</sup>Department of Diabetology, University Hospital Brussels, Belgium, <sup>8</sup>Barbara Davis Center for Childhood Diabetes, University of Colorado at Denver, Aurora, USA.

**Background and aims:** In first-degree relatives of type 1 diabetic patients, we investigated whether diabetes risk assessment solely based on IA-2 and zinc transporter 8 antibody status (IA-2A, resp. ZnT8A) is as effective as screening for autoantibodies (Abs) against insulin (IAA), GAD (GADA) and IA-2 (with or without ZnT8A) in identifying children, adolescents and adults who rapidly progress to diabetes (within 5 years) in the perspective of constituting homogeneous risk groups for immune interventions before diabetes onset.

**Materials and methods:** Abs were determined by radiobinding assays during follow-up of 6444 siblings and offspring aged 0–39 years at inclusion and consecutively recruited by the Belgian Diabetes Registry.

**Results:** We identified 394 persistently IAA<sup>+</sup>, GADA<sup>+</sup>, IA-2A<sup>+</sup> and/or ZnT8A<sup>+</sup> relatives (6.1%). After a median follow-up time of 52 months, 132 relatives developed type 1 diabetes. In each age category tested (0–9 years, 10–19 years and 20–39 years) progression to diabetes was significantly quicker in the presence of IA-2A and/or ZnT8A than in their joint absence. The 5-year progression rate was age-independent if IA-2A and/or ZnT8A were present at baseline but decreased with age if only GADA and/or IAA were detected ( $P = 0.008$ ). Screening for IA-2A and ZnT8A alone identified 74% of the rapid progressors (vs. 65% if positive for  $\geq 2$  Abs among IAA, GADA and IA-2A) and reduced the group of high-risk Ab<sup>+</sup> relatives to be followed by 63%. Positivity for IA-2A and/or ZnT8A was as sensitive as positivity for at least 2 out of 4 antibodies in individuals aged 10–39 years but less sensitive under age 10, an age group generally not considered for immune interventions until now.

**Conclusion:** Screening for IA-2A and ZnT8A alone allows to identify the majority of rapidly progressing prediabetic siblings and offspring regardless of age and is more cost-effective to select participants for intervention trials than conventional screening.

## 268

**Erythrocyte membrane docosapentaenoic acid levels are associated with islet autoimmunity but not progression to type 1 diabetes. The diabetes autoimmunity study in the young**J.M. Norris<sup>1</sup>, M. Kroehl<sup>1</sup>, T.E. Fingerlin<sup>1</sup>, M. Clare-Salzler<sup>2</sup>, G. Eisenbarth<sup>3</sup>, M. Rewers<sup>3</sup><sup>1</sup>Colorado School of Public Health, Aurora, <sup>2</sup>University of Florida, Gainesville, <sup>3</sup>Barbara Davis Center, Aurora, USA.

**Background and aims:** We previously reported that lower omega-3 fatty acid intake and levels in erythrocyte membranes were associated with increased risk of islet autoimmunity (IA) but not progression to type 1 diabetes (T1D) in children at increased risk for T1D. In the current study, we investigated whether specific fatty acids and genetic markers contributed to this increased risk of IA in the Diabetes Autoimmunity Study in the Young (DAISY).

**Materials and methods:** DAISY is following over 2400 children at increased genetic risk for T1D for the development of persistent IA, as defined as being positive for GAD-65, IA-2, or insulin autoantibodies on two consecutive visits, and then for the development of T1D, as diagnosed by a physician. Using a case-cohort design, erythrocyte membrane fatty acids were measured (as a percent of total lipid) prospectively in 109 children who developed IA, with a mean age at onset of 5.8 years, and in 356 children who remained autoantibody negative. Sixty-five of the IA positive children developed T1D over a mean of 4.7 years of follow-up. Fatty acid levels were analyzed as time-varying covariates using Cox regression.

**Results:** Of the membrane omega-3 fatty acids, docosapentaenoic acid (DPA) was strongly inversely associated (HR: 0.23; 95% CI: 0.09–0.55) with IA risk, while alpha-linolenic acid (ALA), eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA) were not, adjusting for HLA-DR status and family history of T1D. None of the membrane omega-6 fatty acids, ie, linoleic acid, gamma linolenic acid, arachidonic acid, were associated with risk of IA. Moreover, none of the omega-3 nor omega-6 fatty acid membrane levels were associated with progression to T1D, adjusting for HLA-DR status, family history of T1D and age at first IA positivity. We cannot examine DPA intake as it is uncommon in the diet. Because membrane DPA levels are determined by endogenous conversion from precursor fatty acids by consecutive desaturation and chain elongation (ALA→EPA→DPA), we hypothesized that omega-3 fatty acid intake would interact with fatty acid desaturation and elongation gene variants to affect risk of IA. We examined 11 variants in *FEN1*, *FADS1*, *FADS2*, *ELOVL2*, *SLC26A10*, *HRH4*, and *SPARC* and total omega-3 fatty acid intake, as determined by annual food frequency questionnaires, on risk of IA. None of the variants were individually associated with risk of IA. However, interactions were detected between omega-3 intake and *FADS1* (rs174556) (interaction  $p=0.037$ ), and *FADS2* (rs174570) (interaction  $p=0.014$ ), adjusting for HLA, family history of T1D, ethnicity, and total energy intake. In children with 1 or 2 *FADS1* minor alleles, increased omega-3 intake is associated with a larger decreased IA risk (HR: 0.60, CI: 0.37–0.97) compared to those without the minor allele (HR: 0.95, CI: 60–1.50), and similarly for children with *FADS2* minor alleles, increased omega-3 intake is associated with a larger decrease in IA risk (HR: 0.42, CI: 0.26–0.69) compared to those with no minor allele (HR: 0.88, CI: 0.60–1.29). Similar interactions were seen for ALA intake alone.

**Conclusion:** The putative protective effect of omega-3 fatty acids on IA may be the result of a complex interaction between intake and genetically-controlled fatty acid desaturation and elongation.

Clinical Trial Registration Number: NIH R01 DK49654, NIH R01 DK32493

## 269

**Analysis of clinical markers for implementation of clinical tool to identify LADA subjects**S. Zampetti<sup>1</sup>, M. Spoleitini<sup>1</sup>, M. Capizzi<sup>1</sup>, G. Campagna<sup>1</sup>, C. Venditti<sup>1</sup>, S. Genovese<sup>2</sup>, A. Giaccari<sup>3</sup>, F. Giorgino<sup>4</sup>, R. Buzzetti<sup>1</sup>, NIRAD Study Group;

<sup>1</sup>Department of Internal Medicine and Medical Specialties, Sapienza, University of Rome, <sup>2</sup>UOC Diabetologia, IRCCS, Sesto San Giovanni, Milano, <sup>3</sup>Department of Endocrinology, University Cattolica, Policlinico Gemelli, Rome, <sup>4</sup>Department of Endocrinology, University of Bari, Italy.

**Background and aims:** Latent autoimmune diabetes of adults (LADA) is characterized by the presence of specific antibodies for autoimmune diabetes, not requiring insulin at diagnosis but having a high risk of progression to insulin dependency. Early diagnosis could have important treatment implications when new therapies to preserve beta-cell function will become avail-

able. The aim of the present study was to develop a clinical screening tool to identify a subpopulation of patients with type 2 diabetes mellitus (T2DM) at high risk of LADA who required GAD antibodies testing.

**Materials and methods:** N=191 LADA subjects and n=382 T2DM patients matched for gender and age, selected from the Non Insulin Requiring Autoimmune Diabetes (NIRAD) study cohort of 4,250 T2DM subjects, were recruited. In all subjects: age at diagnosis, body mass index (BMI), fasting glucose, glycated hemoglobin (HbA1c), waist circumference (WC), total cholesterol, HDL cholesterol, triglycerides and uric acid were evaluated. Statistical analysis was performed using ROC curves (Relative Operating Characteristic) (SPSS v.18). ROC curves allowed us to identify optimal cut-off value indicative for probable presence of GAD antibodies. The cut-off value is that value which corresponds to a point on the ROC curve nearest to the upper left corner of the ROC graph. The area under the ROC curve (AUC) is a scalar measure gauging one facet of performance. Only clinical and biochemical variables whose area under the curve was higher than 0.6 (AUC) were considered for the evaluation of the cut-off.

**Results:** Age at diagnosis, BMI, WC and HbA1c showed an AUC higher than 0.6. These parameters have, therefore, been considered for the evaluation of the cut-off value indicative for the presence of GAD antibodies. The optimal cut-off values were: age of diagnosis <53 years, WC <98.5 cm (males) and <95.5 cm (females), BMI <28.5 kg/m<sup>2</sup> and HbA1c >7.15%. The presence of two or more of these parameters had a 80% sensitivity and 45% specificity with an 0.633 AUC for identifying LADA patients.

**Conclusion:** It is possible to develop a clinical screening tool to increase the probability of identifying LADA patients, however, the analysis of further parameters is essential in order to increase the instrumental clinical prediction specificity.

**Influence of environment, lifestyle, and genes on the risk of LADA (latent autoimmune diabetes in adults) and type 2 diabetes - the ESTRID study**J. Åberg Löfvenborg<sup>1</sup>, M. Dorkhan<sup>2</sup>, L. Groop<sup>2</sup>, B. Rasouli<sup>1</sup>, S. Carlsson<sup>1</sup>;

<sup>1</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm,

<sup>2</sup>Department of Clinical Sciences, Lund University, Malmö, Sweden.

**Background and aims:** The prevalence of autoimmune diabetes is, in similarity with type 2 diabetes mellitus (T2DM), increasing worldwide. Latent autoimmune diabetes in adults (LADA) may be the most common form of autoimmune diabetes and yet the risk factors are to a large extent still unknown. With the aim to shed light on common risk factors, the ESTRID study began in 2010. By collecting data on health and lifestyle as well as genetic and clinical information, we aim to identify modifiable environmental and lifestyle factors that could help in preventing autoimmune diabetes.

**Materials and methods:** ESTRID has a case-control design with information collected through questionnaires and blood samples (DNA, anti-GAD, C-peptide). The cases are recruited through the ANDIS and ANDIU (starting 2012) registries, where all incident cases of diabetes in two Swedish provinces (~1 500 000 inhabitants) are registered. LADA cases are distinguished from T2DM cases by measures of anti-GAD. ESTRID recruits all incident cases of LADA, and for each case four T2DM cases and six randomly selected population controls are recruited. The intention is to have gathered information from 800 cases of LADA and 3000 cases of T2DM, together with 3400 controls, by the end of 2014. ESTRID will be the largest population-based study on LADA to date and have enough power to detect even moderately increased risks. With this data we aim at studying the risk of LADA/T2DM in relation to diet, alcohol, tobacco, physical activity, sleep, infections, psychosocial and socioeconomic factors. For the cases, questionnaire data is collected in close proximity to diagnosis since the information should reflect lifestyle factors that may have affected diabetes onset. Genetic information of > 130 gene variants is available from ANDIS and ANDIU. Controls for the genetic analyses will be obtained from the ongoing epidemiological studies EIRA (rheumatoid arthritis) and EIMS (multiple sclerosis). By using cases from ESTRID and controls from EIRA/EIMS, we will study gene-environment interaction in relation to LADA and T2DM.

**Results:** Since the start in 2010, 672 cases of diabetes (159 LADA and 513 T2DM) together with 768 healthy controls have been recruited, with high response rate in both cases (80.1%) and controls (69.9%). Mean BMI (kg/m<sup>2</sup>) did not differ between LADA cases and controls (27.7 vs. 26.1) but was higher in T2DM (30.6),  $p<0.0001$ . We also find that both LADA and T2DM were more common in men (57.7% and 59.9% of cases were men, as compared to 47.9% of controls). Thus, the risk is markedly lower for women (OR

for LADA=0.58, 95% CI=0.35–0.96). With regard to risk factors, preliminary findings based on a very limited number of cases and a crude assessment of diet indicate that consumption of whole grain bread may reduce the risk of LADA (OR=0.77, 95% CI=0.40–1.50) as well as T2DM (OR=0.57, 95% CI=0.3–1.09). Similar findings are seen for LADA regarding daily consumption of muesli (OR=0.60, 95% CI=0.23–1.56).

**Conclusion:** Being the largest study of its kind, ESTRID provides unique opportunities to study the etiology of LADA. We aim to identify environmental and lifestyle factors affecting disease onset, as well as to contribute to the currently limited knowledge of gene-environment interaction in relation to LADA and T2DM, with the overall goal to find ways to prevent autoimmune diabetes.

## 271

### Study of phenotypic characteristics of patients with latent autoimmune diabetes in adults (LADA) in a Danish population

M. Wod<sup>1</sup>, A. Brandstorp-Boesen<sup>2</sup>, J.Ø. Rathe<sup>3</sup>, K.B. Yderstræde<sup>1</sup>, H. Beck-Nielsen<sup>1</sup>, K. Højlund<sup>1</sup>

<sup>1</sup>Department of Endocrinology, Odense University Hospital, Denmark,

<sup>2</sup>Dermatology, Oslo Universitets sykehus, Rikshospitalet, Oslo, Norway,

<sup>3</sup>Research Unit of General Practice, University of Southern Denmark, Odense, Denmark.

**Background and aims:** Latent autoimmune diabetes in adults (LADA) is the second most common form of diabetes and is considered less understood than its much better characterized counterparts of type 1 diabetes (T1D) and type 2 diabetes (T2D). There is still little agreement on the diagnostic criteria for LADA and therefore it is important to characterize this large subgroup of diabetic patients. A database of newly referred diabetic patients to Odense University Hospital, Denmark tested for anti-GAD65 positivity between 1997 and 2011 is in the process of being established with the aim to investigate phenotypic differences between patients with LADA, T1D and T2D, respectively. This study reports preliminary data from the period 1997–2001.

**Materials and methods:** Anti-GAD65 titer was positive in 226 of 1332 diabetic patients tested between 1997 and 2001. This study includes 54 anti-GAD65 positive diabetic patients, for whom 1) diabetes duration was less than 5 years, and relevant anthropometric and biochemical data were readably available. Thirty-three patients with age at diagnosis > 35 years were defined as LADA, and the others as T1D (n=19). A random group of anti-GAD65 negative diabetic patients with age at diagnosis > 35 years, for whom data were available, was selected among the 1056 anti-GAD65 negative patients, and defined as T2D (n=44). Data included age, gender, BMI, blood pressure, anti-GAD65 levels, HbA1C, and fasting levels of glucose, C-peptide, and lipid profile and are given as mean ± SD.

**Results:** No differences in age (50.9 ± 10.4 vs. 50.8 ± 7.3 years), BMI (27.3 ± 5.5 vs. 29.8 ± 7.9 kg/m<sup>2</sup>), HbA1c, blood pressure, fasting glucose or cholesterol levels were seen between patients with LADA and T2D. Patients with LADA had lower levels of fasting C-peptide (608 ± 403 vs. 918 ± 593 pmol/l; p<0.01) and plasma triglyceride (1.94 ± 1.50 vs. 2.92 ± 2.16 mmol/l; p<0.05) than T2D patients. Compared with the younger (26.6 ± 5.4 years) T1D patients, BMI (27.3 ± 5.5 vs. 23.9 ± 4.43 kg/m<sup>2</sup>; p<0.05) and fasting C-peptide I (608.1 ± 403.4 vs. 280.5 ± 224.5 pmol/l; p<0.01) were higher in LADA patients. Moreover, anti-GAD65 titers were almost 2-fold lower (p<0.01) in LADA than in T1D patients.

**Conclusion:** These preliminary results indicate that LADA patients differ from age-matched type 2 diabetic patients in terms of lower fasting C-peptide and triglyceride levels, and from younger T1D patients by higher BMI, higher fasting C-peptide levels and lower anti-GAD65 titers. Further establishment of a database for the remaining anti-GAD65 positive diabetic patients in the period 1997–2001 and the expected approximately 450 anti-GAD65 positive diabetic patients in the period 2002–2011 will offer the opportunity to search for clinical diagnostics tools to improve the discrimination between patients with LADA, T1D and T2D.

## 272

### Hyperbolic product, cardiometabolic profile and thyroid autoimmunity in phenotypic type 2 diabetics with GAD65 antibodies

Y. Mahadeb, D. Gruson, M. Buysschaert, M.P. Hermans; Endocrinology, Saint-Luc University Clinics, Brussels, Belgium.

**Introduction:** Type 2 diabetes (T2DM) usually results from a combination of insulin resistance and β-cell deficiency, while T1DM results from β-cell destruction associated with islet autoantibodies, including those directed against glutamate decarboxylase (GAD<sub>65</sub> antibodies [GADA]). The clinical impact of low GADA positivity (<10 U/ml) in T2D is debated, especially since screening is rarely performed in routine clinical care and, in addition, there exists a slight subclinical GADA positivity titer in the general population.

**Aims:** To determine the prevalence and the cardiometabolic/autoimmune phenotype of GADA[+] in 524 T2DM patients. Glucose homeostasis determinants were assessed by HOMA: insulin sensitivity (HOMA S); β-cell function (HOMA B); the hyperbolic product [BXS]; and the annualized loss in [BXS].

**Results:** GADA prevalence was 6% (n=30). GADA[+] patients were compared to n=494 GADA[-] controls. There were no differences between groups for age, diabetes duration, and family history of diabetes. There was a higher proportion of women (33 vs. 53%) in GADA[+]. There were no differences between groups in BMI, waist circumference, body fat or visceral fat. HOMA S (mean±1 SD) was lower than normal, with no difference between groups. HOMA B was 52 (38)% (GADA[+]) vs. 61 (43)% (GADA[-]; NS) and the hyperbolic product [BXS] was 29 (19)% (GADA[+]) vs. 27 (17)% (GADA[-]; NS). The annualized rate of [BXS] loss was 1.26 (0.46)%/year (GADA[+]) vs. 1.34 (0.51)%/year (GADA[-]; NS). A metabolic syndrome was present in 83% (GADA[+]) vs. 80% (GADA[-]; NS). There were no differences between groups for classes of oral antidiabetic agents or intensity of glucose-lowering therapy: an OAD mono-, bi- and tri-therapy (± insulin) was prescribed to 20; 10; and 0% (GADA[+]) vs. 17; 24; and 2% (GADA[-]; NS). Insulin, combined with OAD or as monotherapy was prescribed to 36 and 27% of GADA[+] vs 32 and 17% of GADA[-] (NS). Duration of diabetes before insulin therapy was 9 (9) (GADA[+]) vs. 9 (7) years (GADA[-], NS). HbA<sub>1c</sub> was 7.8 (1.5)% (GADA[+]) vs. 7.6 (1.5)% (GADA[-]; NS). In the whole group, prevalence of autoimmune thyroid disease (AITD, anti-TG and/or TPO) was 10%. In GADA[+], this prevalence was significantly increased and equally affected the two sexes: 29% (men), and 25% (women), while for GADA[-] the prevalence was 5% (men) vs. 18% (women; p<0.0001). Micro- and macroangiopathic complications did not differ between groups.

**Conclusion:** The presence of low-titer GADA autoimmunity among unselected T2DM patients was not associated with accelerated β-cell function, nor with any distinctive cardiometabolic phenotype, but for a markedly increased prevalence of autoimmune thyroid disease, especially among men.

## 273

### Zinc transporter type 8 (ZnT8) autoantibodies: prevalence and phenotypic associations in diabetic patients diagnosed >35 years

M.K. Andersen<sup>1,2</sup>, T. Härkönen<sup>3</sup>, P.-H. Groop<sup>2,4</sup>, M. Knip<sup>2,3</sup>, T. Tuomi<sup>1,2</sup>,

<sup>1</sup>Department of Medicine, University of Helsinki, <sup>2</sup>Folkhälsan Research Center, Helsinki, <sup>3</sup>Children's Hospital, University of Helsinki and Helsinki University Central Hospital, <sup>4</sup>Division of Nephrology, Helsinki University Central Hospital, Finland.

**Background and aims:** ZnT8 is an antigen in type 1 diabetes. The ZnT8 protein is encoded by *SLC30A8* where the C-allele of the R325W variant is associated with type 2 diabetes and reduced beta-cell function in non-diabetic subjects. The aim of this study was to assess the prevalence of ZnT8 autoantibodies (ZnT8A) in adult-onset diabetic patients, and to characterize associations between ZnT8A and phenotype, as well as *SLC30A8* and *HLA-DQB1* genotype.

**Materials and methods:** The R and the W isoforms of the ZnT8A were measured in Finnish diabetic patients diagnosed after the age of 35 years (type 1 diabetes: n=274; Latent autoimmune diabetes in adults (LADA): n=273). All patients and 537 non-diabetic control subjects were genotyped for the R325W variant in *SLC30A8* (rs13266634) as well as risk and protective alleles in the *HLA-DQB1* region.

**Results:** ZnT8A were significantly more prevalent in LADA (31.0%) compared with adult-onset type 1 diabetic patients (18.7%, p=0.001). Among the LADA patients, ZnT8A were associated with higher age [ZnT8A posi-

tive vs. ZnT8A negative: 67.4 (19.4) vs. 61.3 (13.0) years,  $p=0.001$ ], higher age at diagnosis [60.0 (17.0) vs. 52.0 (15.3) years,  $p=0.001$ ], and lower insulin secretion during OGTT [incremental AUC S-C-peptide: 1.92 (1.66) vs. 3.60 (2.73) nmol/l,  $p=0.021$ ], whereas no association was observed with duration. Among the adult-onset type 1 diabetic patients, ZnT8A were associated with lower age [47.2 (14.3) vs. 52.9 (11.9) years,  $p=0.003$ ], and shorter duration [4.4 (6.0) vs. 10.8 (11.2) years,  $p<0.0001$ ]. The CC genotype of the R325W variant was associated with LADA with GADA levels below the median [*SLC30A8* CC: OR (95% CI): 1.55 (1.06 - 2.27),  $p=0.024$ ]. No association was observed between the variant and LADA with GADA levels above the median or adult-onset type 1 diabetes. Among the non-diabetic subjects and the LADA patients the C-allele of the R325W variant was associated with reduced insulin secretion [incremental S-C-peptide: *SLC30A8* CC/CT vs. TT: 2.37 (2.40) vs. 3.67 (3.47) nmol/l,  $p=0.007$ ]. ZnT8A prevalence was non-significantly higher in carriers of protective (40.5%) compared to neutral (27.8%) and risk (31.9%) associated *HLA-DQB1* genotypes.

**Conclusion:** The prevalence of ZnT8A was higher, and the autoantibodies did not disappear with longer duration to the same degree in LADA compared with adult-onset type 1 diabetic patients. The *SLC30A8* CC genotype was associated with LADA with low GADA levels. In LADA patients in general, both *SLC30A8* genotype and the presence of ZnT8A affected insulin secretion.

## PS 002 Genetics of type 1 diabetes

### 274

#### Association analysis of 31 type 1 diabetes susceptibility loci in Finnish families

A.P. Laine<sup>1</sup>, J. Ilonen<sup>1,2</sup>, M. Knip<sup>3,4</sup>, The Finnish Paediatric Diabetes Register; <sup>1</sup>University of Turku, <sup>2</sup>University of Eastern Finland, Kuopio, <sup>3</sup>University of Helsinki and Helsinki University Central Hospital, <sup>4</sup>Folkhälsan Research Center, Helsinki, Finland.

**Background and aims:** In addition to the HLA-region conferring major genetic determinants of risk and protection, more than 50 confirmed non-HLA T1D susceptibility loci have been identified in candidate gene studies or in genome wide association studies. The association evidence for many of these loci is based solely on findings in large admixed European and/or North American populations. To investigate the role of these loci in a less heterogeneous population, we have analyzed 36 SNP markers in 31 independent loci for association with T1D in 1761 T1D trio families from Finland. 25 of these loci are considered confirmed, while the evidence for the remaining six loci is sporadic. To explore the possible heterogeneity of effect, the data set was split up based on the affected child's HLA-haplotypes, age at diagnosis and sex.

**Materials and methods:** All subjects with T1D were diagnosed under the age of 15 years according to the WHO criteria. SNP markers were genotyped using the Sequenom platform. The CCR5 delta 32 deletion (rs333) was genotyped using fluorescently labelled PCR primers and automated sequencer. All statistical testing was carried out in the PLINK v1.07 software. Transmission/disequilibrium test (TDT) was used for testing association. TDT p-values were adjusted for multiple testing using a false discovery rate step-up procedure. We consider p-values  $<0.05$  significant for the confirmed loci and adjusted p-values  $<0.05$  for the non-confirmed loci. Breslow-Day (BD) test was used for testing heterogeneity of odds ratio (OR) between subgroups.

**Results:** 17 of the 31 loci showed significant association in our data set. The strongest effect was seen with INS, PTPN22 and IL2RA (respective ORs of 0.44, 1.79 and 0.61), while the rest of the loci ranged from OR=1.31 to no effect. We did not observe any conspicuous differences in effect size compared to the latest meta-analyses, and the direction of effect for each allele was consistent with prior findings. 14 loci did not show association in our study. Five of them were non-confirmed loci and six lacked power to detect their respective discovery effects. Three confirmed loci with good power (assuming discovery effect and our observed allele frequency) were not detected. One of them, CD226, still showed significant association in the 0-4 years subgroup based on age at diagnosis, but CYP27B1 and PRKCQ failed to show any T1D association in the current data set. Significant OR heterogeneity was seen with PTPN22, CTSB and FUT2 (HLA, respective BD p-values of 0.0069, 0.031 and 0.0037) and with LOC150577, INS and CD226 (age at diagnosis, respective BD p-values of 0.046, 0.039 and 0.022) and with LOC646538 and CD69 (sex, respective BD p-values of 0.0090 and 0.035).

**Conclusion:** Our association findings in the Finnish population corresponded well to those reported in the latest meta-analyses using large admixed European and/or North American populations. Lack of population specific susceptibility is not surprising since the confirmed T1D loci have been discovered and replicated mostly in diverse populations and are therefore likely to be universal. The observed significant effect modifications by subgrouping could be an indication of underlying complexity of T1D susceptibility although they need independent confirmation before any claims can be made about their importance.

### 275

#### Genetic risk score predicts beta cell function in children with new onset type 1 diabetes

L. Nielsen<sup>1</sup>, M.M. Andersen<sup>1</sup>, S. Poerksen<sup>1</sup>, C. Brorsson<sup>2</sup>, S. Fredheim<sup>1</sup>, L. Hansen<sup>1</sup>, F. Pociot<sup>2</sup>, H.B. Mortensen<sup>1</sup>;

<sup>1</sup>Department of Pediatrics, Herlev Hospital & University of Copenhagen, Herlev, <sup>2</sup>Glostrup Research Institute, Glostrup Hospital & University of Copenhagen, Glostrup, Denmark.

**Background and aims:** The natural course of type 1 diabetes in newly diagnosed children is characterized by a substantial diversity between individuals. Some children experience a relatively mild onset with limited need of exogenous insulin, while others are more aggressively attacked and require intensive insulin treatment from onset. This variation in disease severity is

poorly understood. The aim of this study is to investigate if the inter-individual variation in disease manifestation can be explained by the patient's genetic background. Therefore, we have investigated the combined impact of several risk alleles of SNPs in type 1 or type 2 diabetes susceptibility genes on the residual beta-cell function and glycaemic control during disease progression in children with new onset type 1 diabetes.

**Materials and methods:** The study is a multicenter longitudinal investigation with 18 participating paediatric centres from 15 countries in Europe and Japan (84% Caucasians). 275 children and adolescents less than 16 yr were included in the study. The residual beta-cell function was estimated by a meal-stimulated C-peptide test 1, 6 and 12 months and capillary samples for centrally determined HbA<sub>1c</sub> were collected 1, 3, 6, 9 and 12 months after disease onset at each center and insulin regimens were recorded. Insulin dose-adjusted HbA<sub>1c</sub> (IDAA1c) was calculated as HbA<sub>1c</sub> % + (4 x insulin dose (units per kilogram per 24 h)). Genotyping of common SNPs in the following genes: *INS*, *TNFAIP3*, *ERBB3*, *IL2RA*, *WFS1*, *HHEX-IDE*, *PPARG* and *SLC30A8* were done by KBioscience using an in-house KASPar assay. The criterion for the SNPs to be included into the risk score model was an individual genotype effect ( $p < 0.05$ ) on stimulated C-peptide during disease progression. The eight qualified SNPs were analyzed for association with disease progression. Main outcome measures for disease progression were described by glycaemic control as assessed by HbA<sub>1c</sub>/ IDAA1c or residual beta-cell function as assessed by stimulated C-peptide.

**Results:** In a multiple regression analyses adjusting for age, sex and HLA risk groups we found a highly significant negative association between numbers of risk alleles and stimulated C-peptide at 1, 6 and 12 months after onset ( $p < 0.0001$ ). In line with this we found a positive significant association between numbers of risk alleles and IDAA1c from 3 until 12 months after onset ( $p = 0.0003, 0.004, 0.007$  and  $0.003$  for 3, 6, 9 and 12 months visits, respectively) when adjusted for age, sex and HLA risk groups. This effect was not seen for the individual SNPs.

**Conclusion:** This study demonstrates large differences in the residual beta-cell function and glycaemic control during disease progression depending on individual genetic background. Thus, it seems we might have different diabetic phenotypes suggesting diabetes management should be individualized already at disease onset where some children may need an insulin pump or other intensified treatment regimens. Furthermore, a combined genetic risk score instead of individual SNPs might improve the association to clinical endpoints and could be considered an important tool when evaluating the pharmacogenetic effect after intervention studies.

## 276

### Baseline patterns and genetic fingerprints related to residual beta cell function and ZnT8 autoantibody profiles in Danish children with new onset type 1 diabetes

S. Pörksen<sup>1</sup>, M.L.M. Andersen<sup>1</sup>, M.A. Rasmussen<sup>2</sup>, J. Svensson<sup>1</sup>, N.T. Hertel<sup>3</sup>, F. Pociot<sup>4</sup>, J.S. Petersen<sup>5</sup>, L. Hansen<sup>1</sup>, H.B. Mortensen<sup>1</sup>, L.B. Nielsen<sup>1</sup>; <sup>1</sup>Pediatrics, Herlev University Hospital, <sup>2</sup>Food Science, Quality and Technology, University of Copenhagen, <sup>3</sup>Pediatrics, Odense University Hospital, <sup>4</sup>Biochemistry, Diagnostic Unit, Glostrup University Hospital, <sup>5</sup>Diabetes Biology & Pharmacology, Novo Nordisk A/S, Måløv, Denmark.

**Background and aims:** The natural history of type 1 diabetes (T1D) disease progression is complex. The purpose of the present remission phase study in a Danish cohort of children with new onset T1D is to explore the natural history of T1D the first 12 months after diagnosis by use of latent factor models which describe unique dynamic profiles of clinical biomarkers related to baseline characteristics and genetic profiles of T1D and T2D related SNPs.

**Material and methods:** We followed 129 children aged < 17 years 12 months after onset of T1D. The data are organized as three individual data blocks: A) Characteristics registered at onset (sex, age, duration of symptoms, HbA<sub>1c</sub>, blood glucose, std. bicarbonate and HLA risk groups); B) Clinical and para-clinical markers (stimulated C-peptide and proinsulin, autoantibodies, HbA<sub>1c</sub>, stimulated blood glucose, daily insulin dose and BMI) collected 1, 3, 6, 9 and 12 months after diagnosis and C) Genotyping of 52 SNPs associated with T1D or T2D in GWA studies. The aim of the statistical analysis is to extract and relate biologically intuitive patterns common between the different data blocks using a multiblock procedure (Coupled Matrix Tensor Factorization). To confirm the validity of the final model, the same patterns of clinical and laboratory characteristics were investigated in the international Hvidoere Remission Phase cohort - an independent, similar cohort of newly diagnosed children.

**Results:** The model with lowest residual variation was chosen and by use of this model two components of relevance, explaining 21.6% of the total variation in the dataset, was identified. The first component assigned 'beta-cell function', described a decrease in stimulated C-peptide and proinsulin levels in combination with an increase in stimulated blood glucose, glucagon and daily insulin dose per kg bodyweight during the first 12 months after onset. Furthermore this component was positively associated with the number of risk alleles of *WFS1*, *CDKN2A/2B* and *RNLS* ( $p = 0.0004$ ), and in addition positively associated with baseline characteristics such as young age, presence of DKA and long duration of disease symptoms ( $p = 0.006$ ). The second component assigned 'ZnT8 autoantibodies (ZnT8Ab)' indicated that high ZnT8Ab, which is related to better residual beta-cell function, and low postprandial glucagon levels are associated with a combined genetic profile of risk alleles from SNPs in type 1 diabetes related genes: *IFIH1*, *TCF2*, *TAF5L*, *IL2RA* and *PTPN22* and protective alleles from the *ERBB3* gene ( $p = 0.0005$ ). The derived patterns where found replicable in the independent Hvidoere Remission Phase Cohort.

**Conclusion:** In conclusion, complex latent factor analysis on data from a clinically well characterised Danish Remission Phase Cohort can describe patterns present at diagnosis which is associated to residual beta cell function and glycaemic control during the first 12 months of clinical disease and identify humoral immune responses and genetic interacting factors that were not recognised by classical univariate analyses

## 277

### Polymorphisms in the INS and IKZF4 genes are associated with insulin autoantibodies at the diagnosis of type 1 diabetes

J. Lempainen<sup>1</sup>, A.P. Laine<sup>1</sup>, M. Knip<sup>2,3</sup>, J. Ilonen<sup>1,4</sup>, The Finnish Paediatric Diabetes Register;

<sup>1</sup>University of Turku, <sup>2</sup>University of Helsinki and Helsinki University Central Hospital, <sup>3</sup>Folkhälsan Research Center, Helsinki, <sup>4</sup>University of Eastern Finland, Kuopio, Finland.

**Background and aims:** More than 50 loci outside the HLA region have been confirmed to affect type 1 diabetes (T1D) risk. However, their effect on the beta-cell autoimmunity is poorly described. We analysed the association of 35 SNP markers from 31 independent loci previously associated with T1D with the presence of T1D-associated autoantibodies at the time of T1D diagnosis.

**Materials and methods:** The study cohort comprised 1556 children from the Finnish Paediatric Diabetes Register. All subjects were diagnosed with T1D before 15 years of age between years 1998 and 2009. Serum samples were collected within 14 days after the T1D diagnosis (mean 5.2 days). SNPs were genotyped using the Sequenom platform. The association between various genotypes and positivity for antibodies against islet cells, insulin (IAA), glutamic acid decarboxylase, islet antigen 2 and zinc transporter-8 (ZnT8A) were analysed using Chi Square test and corrected for multiple testing (31 loci).

**Results:** INS gene polymorphism rs689 was strongly associated with IAA positivity at the time of T1D diagnosis ( $p = 0.00012$ ) but not with positivity to other autoantibodies tested. In addition, the IKZF4 C/A polymorphism (rs1701704) and rs2292239 in the nearby ERBB3 gene showed association with IAA ( $p = 0.014$  and  $0.031$ , respectively) but were not associated with other autoantibodies. rs6546909 in the DQX1 gene showed borderline association with ZnT8A ( $p = 0.031$ ). The other SNPs analysed showed no significant association with any autoantibodies tested. The presence of T1D risk associated INS AA genotype was associated with IAA, 544 (44.8%) subjects with AA genotype were IAA positive compared to 89 (29.4%) and 7 (30.4%) with AT and TT genotypes, respectively. In contrast, the presence of the T1D-risk associated C allele of the IKZF4 marker was inversely associated with IAA. 66 (34.0%) subjects homozygous for the disease associated C allele and 286 (38.5%) subjects with the heterozygous CA genotype were IAA positive compared to 278 (47.4%) with the AA genotype.

**Conclusion:** While the INS gene risk genotype was associated with the presence of IAA, the IKZF4 T1D risk allele was inversely associated with IAA. In the same cohort, the OR for the T1D risk effect of the C allele was 1.3, and its effect was strongest among subjects diagnosed between 10 to 15 years of age. These results suggest that the IKZF4 risk allele is more important among subjects with beta-cell autoimmunity initiated later during childhood. The IKZF4 gene encodes a zinc finger protein specifically expressed in lymphocytes and is implicated in the control of lymphoid development. Our results suggest that the IKZF4 polymorphism is included in a pathway of beta-cell autoimmunity alternative for the route characterized with IAA and development of T1D during early childhood.

## 278

# Immunogenetic determinants of childhood type 1 diabetes in European and non-European immigrants to Sweden in the Better Diabetes Diagnosis Study

A.J. Delli<sup>1</sup>, B. Lindblad<sup>2</sup>, A. Carlsson<sup>3</sup>, H. Elding-Larsson<sup>1</sup>, G. Forsander<sup>2</sup>, S.A. Ivarsson<sup>1</sup>, J. Ludvigsson<sup>4</sup>, I. Kockum<sup>5</sup>, C. Marcus<sup>6</sup>, U. Samuelsson<sup>7</sup>, E. Örtqvist<sup>8</sup>, L. Groop<sup>1</sup>, Å. Lernmark<sup>1</sup>;

<sup>1</sup>Department of Clinical Sciences, Lund University, Malmö, <sup>2</sup>Department of Pediatrics, Sahlgrenska Academy, University of Gothenburg, <sup>3</sup>Department of Pediatrics, Lund University, Lund, <sup>4</sup>Department of Clinical and Experimental Medicine, Linköping University, <sup>5</sup>Department of Clinical Neurosciences, Karolinska Institute, Stockholm, <sup>6</sup>Department of Clinical Science, Intervention and Technology, Karolinska Institute, Stockholm, <sup>7</sup>Diabetes Research Center, Linköping University Hospital, <sup>8</sup>Department of Woman and Child Health, Karolinska Institute, Stockholm, Sweden.

**Background and aims:** We examined whether non-Europeans compared to European and Swedish patients, present different genetic determinants associated with their T1D and whether these determinants affected the types and frequencies of islet autoantibodies and metabolic indicators at diagnosis.

**Materials and methods:** We recruited 2538 newly diagnosed T1D patients (<18y, 55% male) from the Better Diabetes Diagnosis (BDD) study. Country of birth of all parents and grandparents identified three subgroups; non-Europeans (148; 5.8%) and Europeans (86; 3.5%) and Swedes (2304; 90.7%)

**Results:** The HLA-DQ2/x (where x is any other haplotype except DQ8) predominated the non-Europeans (46%), compared to Europeans (26%;  $p=0.002$ ) and Swedes (15%;  $p=0.0005$ ). Furthermore, the none-DQ2-non-DQ8 (x/x) was more prevalent in non-Europeans (26%) compared to Europeans (23%;  $p=0.68$ ) and Swedes (14%;  $p=0.0005$ ) who had more DQ8/x (41%;  $p=0.0005$ ) and DQ2/8 (31%;  $p=0.0005$ ), compared to non-Europeans and Europeans. The PTPN22 (R620W) risk T allele (CT+TT) was extremely uncommon (5%) in the non-Europeans, compared to 14% in Europeans and 35% in Swedes ( $p=0.0005$ ). The T2D-associated zinc transporter 8 gene (SLC30A8) CC genotype dominated the non-Europeans (72%), compared to 50% in Europeans and 46% in Swedes ( $p=0.0005$ ). The FTO AA risk genotype was slightly more frequent in non-Europeans (24%) than Europeans (14%;  $p=0.12$ ) and Swedes (17%;  $p=0.051$ ). Overall, the FTO AA genotype was negatively associated with multiple autoantibodies ( $p=0.003$ ) and ZnT8-Tryptophan (W) antibodies ( $p=0.015$ ). The frequencies and types of islet autoantibodies were closely related to the genetic determinants. Consequently, non-Europeans were more likely to be autoantibody negative than Europeans and Swedes (11%, 8% and 6% respectively;  $p=0.07$ ) and less likely to develop multiple ( $\geq 2/6$ ) autoantibodies (64%, 81% and 79% respectively;  $p=0.005$ ). In the immigrant group (non-Europeans and Europeans), higher levels of mean HbA1c (mmol/mol) (105; SD=26 and 108; SD=25 respectively) than Swedes (94; SD=27) were observed in females ( $p=0.0005$ ) but not males ( $p=0.85$ ). Although the prevalence of DKA at diagnosis was less in Swedes (15%) than non-Europeans (22%) and Europeans (23%),  $p=0.009$ ; Swedish patients who develop DKA were older ( $p=0.0005$ ).

**Conclusion:** Our findings showed a gradient-like pattern in presence of immunogenetic markers of T1D. Non-Europeans, compared to Europeans and Swedes, develop diabetes with less T1D risk genes and more T2D-associated genes and therefore they had lesser islet autoantibodies suggesting a possibility of shared T1D and T2D pathways in their susceptibility to develop diabetes.

# ACE genotype and phenotype and 12-year all-cause mortality in type 1 diabetes

L.H. Færch<sup>1</sup>, A.-S. Sejlind<sup>1</sup>, U. Pedersen-Bjergaard<sup>1</sup>, B. Thorsteinnsson<sup>1,2</sup>;

<sup>1</sup>Dept. of Cardiology Nephrology and Endocrinology 0652, Hypoglycaemia research group, Hillerød, <sup>2</sup>Faculty of Health, Copenhagen, Denmark.

**Background and aims:** The D allele of the ACE I/D polymorphism, which confers the phenotype of high ACE activity, is implicated in increased morbidity in type 1 diabetes. D-allele carriage is associated with faster progression of diabetic nephropathy, development of cardiac hypertrophy, and hypertension. Diabetic nephropathy is associated with increased mortality. In both type 1 diabetes and in general cardiac hypertrophy and hypertension are associated with increased mortality. We studied whether D-allele carriage and high serum ACE activity are as-

sociated with overall mortality after 12 years in a type 1 diabetic cohort. **Materials and methods:** A cohort of 265 adult patients with type 1 diabetes was recruited in 1999 to 2000 and classified according to ACE I/D polymorphism, serum ACE activity and treatment with RAS blocking agents. After 12 years the cohort was followed up for all-cause mortality. All patients were included in the genotype analysis, whereas only subjects not treated with any RAS blocking agents ( $n=166$ ) - and thus with un-modified spontaneous ACE activity - were included in the phenotype analysis. The cohort consisted of 157 men, with a median diabetes duration of 20 years. Nephropathy was present in 25 percent and 20 percent of the cohort were on ACE inhibitors. We used Kaplan-Meier method to evaluate the mortality rate for both genotype and ACE activity.  $P<0.05$  (two-sided) was considered to be significant. **Results:** A total of 39 patients (15 %) died during follow-up. Mortality rate was lower in II-carriers compared to the D-carriers, 6.6 % vs. 17.2 % ( $p=0.048$ ). This is depicted in the Kaplan-Meier plot below. Thirteen of the patients not on RAS blocking treatment (7.8 %) died during follow-up. The mortality rate of zero in the lowest ACE quartile was lower than that of the three upper ACE quartiles 10.6% ( $p=0.029$ ). **Conclusion:** In type 1 diabetes carriage of the D-allele of the ACE I/D polymorphism - and correspondingly high spontaneous serum ACE activity - is associated with increased long-term all-cause mortality in a Kaplan-Meier survival plot.

# The promoters of genes associated with type 1 and type 2 diabetes seem to have some specific features

C. Ionescu-Tirgoviste<sup>1</sup>, P. Gagniuc<sup>2</sup>, C. Guja<sup>1</sup>;

<sup>1</sup>1st Clinic of Diabetes, National Institute of Diabetes, Nutrition and Metabolic Diseases, <sup>2</sup>Institute of Genetics, Bucharest, Romania.

**Background and aims:** Genome-wide association studies (GWAS) made in the last decade raised the number of genes associated with type 1 (T1D) and type 2 (T2D) diabetes to about 50 genes for each. The environmental factors seem to play an important role in the expression of these genes through transcription factors that act on promoters. For this reason in this paper we tried to analyze by using an original method the promoter sequences (about 500 pb) of various genes associated with the two main phenotypes of diabetes, which may shed a new light on the diabetogenic mechanisms.

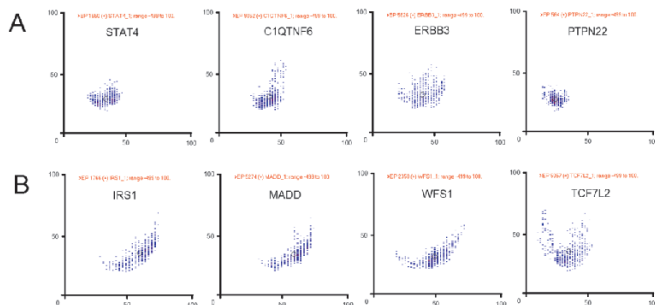

**Materials and methods:** Using available databases we analyzed a total of 25 promoters of genes associated with T1D and T2D. In order to measure the structural features of promoters sequences, we used our original method of analysis based on Kappa Index of Coincidence (Kappa IC). Kappa IC is a cryptographic method not implemented so far in DNA sequence analysis.

Our method measures the degree of randomization of a DNA sequence. Unlike sequence alignment algorithms, our method uses a comparison between the frequency and the nucleotide content of a promoter sequence. Among the analyzed promoters of genes associated with T1D, we mention the C1QTNF6, CD55, ERBB3, PTPN22 and STAT4 gene promoters (Figure 1A) and for T2D the CAMK1D, CDC123, CDKAL1, CDKN2AIP, DUSP9, HHEX, HMG2A, HNF1B, IRS1, NOTCH2, PPARG, PROX1, TCF7L2, THADA, TLE4, TP53INP1, TSPAN8, VPS13C, WFS1 and ZFAND6 gene promoters (Figure 1B).

**Results:** Our analysis shows that the promoters associated with T1D contain similar patterns that may suggest common mechanisms of action in their biological pathways. Furthermore, all genes involved in autoimmunity may have promoters with such common characteristics. In contrast, promoters of genes associated with T2D seem to be similar in variability to those found in our genome-wide analysis of promoters. This suggests that the mechanisms involved in T2D are more numerous and less specific.

**Conclusion:** In the future of great interest will be if the same patterns found in T1D will be identified also in other autoimmune diseases. Also, a separate study of obesity associated vs. not associated T2D could further clarify the relationship between these two metabolic disorders.

### Genetic and expressional evidence for involvement of post-translational modifications as potential triggers of immune intolerance in human islets

A.J. Overgaard<sup>1</sup>, F. Piva<sup>2</sup>, C.A. Brorsson<sup>1</sup>, C.H. Bang-Berthelsen<sup>1</sup>, J. Nerup<sup>1</sup>, F. Pociot<sup>1</sup>, J. Størling<sup>1</sup>

<sup>1</sup>Glostrup Research Institute, Glostrup University Hospital, Denmark,

<sup>2</sup>Polytechnic University of Marche, Ancona, Italy.

**Background and aims:** The loss of immune tolerance to the insulin-producing beta-cells leading to type 1 diabetes (T1D) is unclear. Although several auto-antigens are known, none of these except for insulin are beta-cell-specific and do therefore not explain the specific T-cell-mediated destruction of the beta-cells. We hypothesize that the inflammatory environment in the islets in the initiation phase of T1D pathogenesis induces post translational modifications (PTMs) of beta-cell proteins leading to creation of new antigenic epitopes that are non-immune-tolerant and thus stimulate T-lymphocyte reactivity. We further suggest that part of the genetic susceptibility to T1D may be explained by variation in genes that encode enzymes involved in PTM processes. The aim of this study was to identify genes encoding PTM enzymes in islets that may play a role for induction of beta-cell immune intolerance in T1D.

**Materials and methods:** A comprehensive bioinformatics survey was used to identify all potential proteins involved in selected PTM categories (acetylation, amidation, citrullination, glycosylation, nitrosylation and sumoylation). Genome-wide association scan (GWAS) data was used to map T1D-associated single nucleotide polymorphisms (SNPs) to the genes encoding the identified PTM enzymes. Gene expression of candidates was examined by micro array analysis of human islets exposed for 48 hours to pro-inflammatory cytokines (IL-1+IFN+TNF).

**Results:** We identified a total of 292 genes that encode proteins involved in the six PTM categories. Impressively, 120 of these genes were found to contain T1D-associated SNPs ( $p < 0.05$ ). A Q-Q plot of the results demonstrated a strong enrichment of T1D-associated SNPs in these genes as compared to expected by random chance. Human islet gene expression analysis revealed that 19 of the genes that harboured significant SNPs also were significantly

regulated by cytokines ( $n=4$ ,  $p < 0.05$ ) highlighting that these genes may be of particular interest in the context of regulating PTMs in the islets and beta-cells during inflammatory stress.

**Conclusion:** These observations strongly support a genetic component in T1D risk related to control of PTMs and suggest that the roles of these specific enzymes in islets and pancreatic beta-cells should be further investigated.

### Reduced gene expression of killer cell lectin-like receptor subfamily C, member 3, an activating receptor of natural killer cells, in patients with fulminant type 1 diabetes

S. Nakata<sup>1</sup>, A. Imagawa<sup>1</sup>, Y. Miyata<sup>1</sup>, A. Yoshikawa<sup>1</sup>, K. Okita<sup>1</sup>, T. Funahashi<sup>1,2</sup>, S. Nakamura<sup>3</sup>, K. Matsubara<sup>3</sup>, H. Iwahashi<sup>1</sup>, I. Shimomura<sup>1</sup>

<sup>1</sup>Department of Metabolic Medicine, <sup>2</sup>Department of Metabolism and

Atherosclerosis, Graduate School of Medicine, Osaka University, Suita,

<sup>3</sup>DNA Chip Research Inc., Yokohama, Japan.

**Background and aims:** Fulminant type 1 diabetes is an independent subtype within type 1 diabetes that is characterized by the remarkably rapid destruction of pancreatic beta cells. This subtype accounts for approximately 20% of acute-onset type 1 diabetes in Japan and has been reported worldwide, particularly in East Asia. The accumulating lines of evidence suggest that viral infection would contribute to beta cell death, however, the detailed pathophysiology has not been understood. In this study, we tried to clarify the mechanisms involved in the development of fulminant type 1 diabetes by a comprehensive approach using gene expression microarray analysis in peripheral blood cells.

**Materials and methods:** Thirty-two patients with type 1 diabetes (16 fulminant type 1 and 16 classical type 1A) and 9 non-diabetic control subjects were enrolled in this study. All patients had recovered from ketosis at disease onset and had been receiving intensive insulin injection therapy, which means that all patients and controls were free from of metabolic derangements at the time of blood sampling. We performed gene expression microarray (Agilent Whole Human Genome Oligo Microarray 44k (Design ID: 014850), Agilent Technologies, USA) analysis using peripheral blood cells in a small group of subjects, then performed a volcano plot analysis to determine the genes that were differentially expressed between fulminant type 1 diabetes and type 1A diabetes or control. We performed real-time RT-PCR using peripheral blood cells and natural killer (NK)-enriched cells isolated from peripheral blood mononuclear cells (PBMCs). We also determined the proportion of NK cells in PBMCs using flow cytometry.

**Results:** Gene expression microarray analysis revealed that killer cell lectin-like receptor subfamily C, member 3 (KLRC3), which is known as a NK cell activating receptor, reduced expression in fulminant type 1 diabetes compared with both control and type 1A diabetes. Next, we confirmed that the expression of KLRC3 was significantly lower in fulminant type 1 diabetes compared with the controls using peripheral blood cells (i.e., the relative gene expression was  $0.55 \pm 0.26$  and  $1.00 \pm 0.78$  for 16 patients with fulminant type 1 diabetes and 9 controls, respectively;  $p = 0.0412$ ) and NK-enriched cells isolated from PBMCs (i.e., the relative gene expression as  $0.38 \pm 0.30$  and  $1.00 \pm 0.78$  for 15 patients with fulminant type 1 diabetes and 9 controls, respectively;  $p = 0.0108$ ) by real-time RT-PCR. Further study revealed that the proportion of NK cells in PBMCs was significantly lower in fulminant type 1 diabetes than in controls using flow cytometry. The proportion of NK cells in PBMCs correlates with the duration of the onset of fever to hyperglycemic symptoms in fulminant type 1 diabetes.

**Conclusion:** Our study suggests that impairment of NK cell activity is caused by reduced NK activating receptor gene expression and reduced proportion of NK cells in fulminant type 1 diabetes. Impairment of NK cell activity would be associated with the insufficient viral inactivation leading to rapid destruction of pancreatic beta cells in fulminant type 1 diabetes.

## 283

**Transcriptome analysis of the murine type 1 diabetes locus Idd6.3**U.C. Rogner<sup>1</sup>, B. Lebaillly<sup>1</sup>, C. He<sup>1,2</sup>, P. Avner<sup>1</sup>;<sup>1</sup>URA2578 GMM, Institut Pasteur, <sup>2</sup>Inserm, Paris, France.

**Background and aims:** Our study aims at the characterization of type 1 diabetes loci (Idd) on mouse chromosome 6 in the nonobese diabetic mouse. Idd6 is a locus that controls diabetes development via the activity of CD4 T cells. C3H alleles at Idd6 are protective in diabetes transfer assays. This phenotype has been recently localised to the 700 kb interval of Idd6.3, containing about 10 genes. These include the candidate Aryl hydrocarbon receptor nuclear translocator-like 2 (Arntl2), a homologue of the Arylhydrocarbon receptor. Our current experiments were designed to identify putative downstream targets of Idd6.3 and Arntl2.

**Material and methods:** CD4 T cells were isolated by MACS from three spleens of NOD.C3H congenic females 6.VIIIa (NOD alleles at Idd6.3) and 6.VIIIc (C3H alleles at Idd6.3), pooled and activated for 24 h in the presence of anti-CD3, anti-CD28, and IL2. Three independent biological samples of RNA were then used for microarray analysis (Affymetrix Exon 1.0 ST). Genes with expression differences ( $p < 0.05$  in BH-FDR test) were considered for further analysis using the Database for Annotation, Visualization and Integrated Discovery (DAVID) v6.7.

**Results:** The comparison of the transcriptome of CD4 T cells between two the two Idd6.3 strains showed differences in expression of 99 genes. 69 genes were downregulated in the strain 6.VIIIc compared to 6.VIIIa, whilst 30 genes were upregulated in 6.VIIIc versus 6.VIIIa. Clustering analysis using DAVID at medium stringency revealed 12 functional clusters. These included, in order, ribosomal proteins, cytokines, positive regulation of the immune system, immune defense response, cell migration, hemopoiesis, protein transport, cell fraction, membrane proteins, apoptosis, ion binding, and DNA binding. Interestingly, several immune relevant genes in the interferon pathway appear to be deregulated (see table).

**Conclusion:** These results suggest an implication of the 700 kb Idd6.3 region in the regulation of the expression of several cytokines and antigens. Their deregulation may be associated with decreased diabetogenic activity of the 6.VIIIc derived splenocytes. The data of the transcriptome experiments will also be combined with the NOD and C3H sequence analysis in the Idd6.3 region.

**Immune relevant genes influenced by Idd6.3**

gene	fold change (6.VIIIc/a)	function
IFNg	-1,48	interferon-gamma, immunoregulatory cytokine
IL24	-1,49	interleukin 24, controls cell survival and proliferation
CCL22	-1,41	C-C motif chemokine 22
CD24a	-1,42	CD24 antigen, signal transducer
CD55	-1,56	decay-accelerating factor (DAF), regulates the complement system
LCP2	-1,72	lymphocyte cytosolic protein 2, T cell development and activation
IFITM3	-1,49	interferon-induced transmembrane protein 3, immune defense
CCL19	+1,37	C-C motif chemokine 19, role in lymphocyte recirculation
IFNz	+1,61	interferon zeta/limitin, immunomodulatory cytokine

**Parent-of-origin effect of GRB10 variant on insulin and glucose levels during OGTT in the pathogenesis of type 2 diabetes**W. Poon<sup>1</sup>, P. Almgren<sup>1</sup>, A. Stančáková<sup>2</sup>, Y.-C. Cheng<sup>3</sup>, K.D. Silver<sup>3</sup>, A.R. Shuldiner<sup>3</sup>, M. Laakso<sup>2</sup>, L. Groop<sup>1</sup>, V. Lyssenko<sup>1</sup>, for the MAGIC investigators;<sup>1</sup>Department of Diabetes & Endocrinology, Institution for Clinical Sciences in Malmö, Lund University, Malmö, Sweden, <sup>2</sup>Department of Medicine, University of Eastern Finland and Kuopio University Hospital, Kuopio, Finland, <sup>3</sup>Division of Endocrinology, Diabetes and Nutrition, University of Maryland School of Medicine, Baltimore, USA.

**Background and aims:** Growth factor receptor-bound protein 10 (GRB10) is a negative regulator of insulin receptor signaling and has previously been implicated in the type 2 diabetes (T2D) pathogenesis. Recently, in the GWAS meta-analysis for insulin secretion traits (MAGIC), we identified a *GRB10* SNP associating with insulin secretion during OGTT. *GRB10* is an imprinted gene and has been shown to have tissue- and isoform-specific expression. Imprinted genes often show different parental transmissions. The aim of our study was to evaluate the parent-of-origin effect (POE) of the *GRB10* variant on insulin and glucose levels during OGTT.

**Materials and methods:** The *GRB10* variant was genotyped in a total of about 2300 trios (child/mother/father) from the Swedish-Finnish Trios, Amish Family Diabetes and EUGENE2 studies. Offspring were grouped according to parental allele transmission (e.g. ApGm = A paternal / G maternal). POE on insulin traits and glucose levels was studied using linear regression analysis.

**Results:** In the combined analyses, the maternally transmitted A-allele was associated with ~15% lower early insulin response to glucose at 30 min (CIR,  $p = 0.015$ ), ~15% lower CIR adjusted for insulin sensitivity index ( $p = 0.013$ ), ~13% lower insulin at 30 min during OGTT ( $p = 0.012$ ), ~14% lower insulin at 30 min adjusted for BMI ( $p = 0.006$ ), ~11% lower area under the insulin curve during OGTT ( $p = 0.007$ ) and ~12% lower total insulin response to glucose (AUCIns/AUCGluc,  $p = 0.002$ ). In the Swedish-Finnish Trios, the maternal A-allele was associated with ~19% lower fasting plasma glucose during OGTT ( $p = 0.001$ ). Preliminary data in the Swedish-Finnish ( $-0.193 \pm 0.059$ ,  $p = 0.001$ ) and EUGENE Trios ( $-0.019 \pm 0.014$ ,  $p = 0.17$ ) also suggest lower fasting plasma glucose level in the offspring with maternal A-allele compared to maternal G-allele.

**Conclusion:** These results demonstrate that the expected effect of reduced insulin secretion on increase in glucose levels was not seen suggesting that the effect of the risk A-allele of the *GRB10* variant could also include other regulators of glucose like glucagon.

**Differential effects of type 2 diabetes and fasting glucose/insulin associated loci on insulin secretion stimulated by glucose, GLP-1 or arginine as measured by hyperglycaemic clamps**N. van Leeuwen<sup>1</sup>, G. Nijpels<sup>2</sup>, T.W. van Haeften<sup>3</sup>, P.E. Slagboom<sup>4</sup>, E.J. de Geus<sup>5</sup>, J.M. Dekker<sup>2</sup>, D.I. Boomsma<sup>5</sup>, A. Fritsche<sup>6</sup>, E.M. Eekhoff<sup>7</sup>, L.M. 't Hart<sup>1,4</sup>;<sup>1</sup>Molecular Cell Biology, Leiden University Medical Center, Netherlands,<sup>2</sup>The EMGO institute for Health and Care Research, VU University Medical Center, Amsterdam, Netherlands, <sup>3</sup>Department of Internal Medicine, Utrecht University Medical Center, Netherlands, <sup>4</sup>Section Molecular Epidemiology, Department of Medical Statistics and Bioinformatics, Leiden University Medical Center, Netherlands, <sup>5</sup>Biological Psychology, VU University, Amsterdam, Netherlands, <sup>6</sup>Department of Internal Medicine, Eberhard-Karls University of Tübingen, Germany, <sup>7</sup>Diabetes Center, Department of Internal Medicine, VU University Medical Center, Amsterdam, Netherlands.

**Background and aims:** Currently approximately 65 loci associate with type 2 diabetes, fasting glucose and/or fasting insulin in GWAS and several of these have been associated with beta-cell function and/or insulin resistance, calculated as HOMA-B and HOMA-IR from OGTT. We assessed whether these loci are associated with glucose, glucagon-like peptide 1 (GLP-1) or arginine stimulated insulin secretion during hyperglycaemic clamps, the gold standard for assessment of beta cell function.

**Materials and methods:** Four hundred and fifty volunteers (260 NGT; 190 IGT) underwent a 2-h hyperglycaemic clamp at 10 mmol/l glucose. First- and second-phase glucose-stimulated insulin secretion (GSIS), insulin sensitivity index and disposition index were calculated. A subset had an extended clamp with additional GLP-1 and arginine stimulation ( $n=228$ ). Genetic variation in the 65 loci was assessed using the Cardio-Metabochip. Data from linear regression (GEE) represent results for the best associated SNP in the 50 loci that are well represented on the Cardio-Metabochip. Associations between genetic variation and glucose, GLP1 or arginine stimulated insulin secretion were regarded significant if at least one beta cell measure reached the study wide significance threshold of  $p < 2 \times 10^{-4}$  and for the other beta cell measures at least  $p < 2 \times 10^{-3}$ .

**Results:** Nine T2D and/or fasting glucose/insulin loci were significantly associated with beta cell function. Gene variants in *GIPR*, *CDKAL1*, *ADAMTS9*, *SLC2A2* and *PROX1* showed the largest association with the disposition index and a nominal ( $p < 2 \times 10^{-3}$ ) association with first phase GSIS but not with 2nd phase GSIS, GLP-1 or arginine stimulated insulin secretion. *JAZF1* was associated with both 1st and 2nd phase GSIS but not with the other stimuli. Interestingly, the effect of *FADS1* was only present after arginine stimulation while *DGKB* affected both arginine and GLP-1 stimulated insulin secretion but none was associated with glucose stimulated insulin secretion. Finally *HLA-DQB1* affected the insulin sensitivity index but not beta cell function. Furthermore, another 20 loci showed nominal significant associations with insulin response to one or more of the secretagogues.

**Conclusion:** T2D and fasting glucose/insulin loci are in this study associated with different and specific aspects of beta-cell function measured by hyperglycaemic clamp and three different stimuli. These findings provide further insight into the mechanisms involved in proper functionality of the pancreatic beta-cells and the development of T2D.

### New insights on the involvement of the intronic SNP rs7903146 on alternative splicing of TCF7L2

M. Pradas-Juni<sup>1,2</sup>, N. Nicod<sup>1,3</sup>, E. Fernández-Rebollo<sup>1,2</sup>, J. Valcárcel<sup>4</sup>, R. Gomis<sup>1,2</sup>;

<sup>1</sup>Diabetes and Obesity Laboratory, IDIBAPS, Barcelona, <sup>2</sup>CIBERDEM, Barcelona, <sup>3</sup>Instituto IMDEA, Madrid, <sup>4</sup>Centre de Regulació Genòmica, Barcelona, Spain.

**Background and aims:** The etiology of type 2 diabetes mellitus (T2D) is complex and involves an interplay between environmental risk factors and susceptible genetic background. To date, several GWAS have strongly correlated the single nucleotide polymorphism, SNP rs7903146 (reference/alternative: C/T) in intron 3 of the transcription factor-7-like 2 (TCF7L2) gene, with an increased risk of T2D. TCF7L2 is a Wnt signaling transcription factor encoded by 17 identified exons, with a complex splicing pattern, giving rise to several isoforms expressed differentially in several tissues including pancreas. One of these isoforms has been associated to a protective effect on  $\beta$ -cell function and survival whereas some others to  $\beta$ -cell apoptosis. Our hypothesis is that T2D individuals carrying the T/T risk genotype express different spliced TCF7L2 transcripts. The main goal was to characterize TCF7L2 spliced variants in immortalized B-lymphocytes, more precisely to study the expression of the different spliced transcripts, to determine the promoter methylation, the possibility of an extra exon in intron 3 and the protein levels.

**Materials and methods:** We used immortalized B-lymphocytes from 8 subjects, 4 controls and 4 diabetic, each group with 2 individuals homozygous for each genotype. To characterize and measure the different transcripts expression, we designed a set of primers covering the spliced transcripts. To determine the promoter methylation we performed a COBRA assay. To analyze the possibility of an extra exon within intron 3, we interrogated the surrounding genomic area of the SNP using two different databases: the Server Developer by Gil Ast (<http://ast.bioinfo.tau.ac.il>) and a database by Hagen Tilgner (CRG); and then we analyzed the predicted acceptor and donor splice sites using NetGene2 software. Finally we studied the total protein levels by immunoblotting.

**Results:** The expression of total mRNA shows differences between T/T controls and diabetic ( $1.57 \pm 0.06$  vs  $0.73 \pm 0.17$ , respectively). Otherwise, our results did not show differences on exons 3-4-5 splicing. We found a decreased expression, in T/T diabetic patients, of the transcripts including the extra nucleotides in exon 7 ( $0.66 \pm 0.13$ , ctrl:  $0.93 \pm 0.39$ ) and exon 9 ( $0.51 \pm 0.05$ , ctrl:  $0.78 \pm 0.07$ ). Finally, we did not find evidence for the expression of the spliced transcript on exons 12-13-17. Because of that, we checked whether a change

in promoter methylation could be related to the expression results, but none were detected. We found that T/T genotype contains motifs that have been associated as splicing repressors, correlating with a skipped exon. On the other hand, the C/C genotype has different motifs identified as splicing enhancers. Therefore, to rule out these predicted exons, we performed qRT-PCR experiments, but we did not find any of the predicted extra exons. Finally, we found lower TCF7L2 total protein levels in individuals carrying the T/T genotype (T/T:  $0.34 \pm 0.08$ ; C/C:  $1.00 \pm 0.16$ ), supporting our hypothesis that this SNP may generate different splicing isoforms and it could induce changes in protein folding and/or function.

**Conclusion:** Our results show that in T2D patients, there is no preference in the splicing pattern of exon 3-4-5, and the inclusion of extra nucleotides at exons 7 and 9 in T/T diabetic patients is correlated with a reduction in total protein levels.

### A novel cis-regulatory SNP in the GCK locus

M. Claussnitzer<sup>1,2</sup>, M. Fugmann<sup>1</sup>, H. Hauner<sup>1,2</sup>, H. Laumen<sup>1,2</sup>;

<sup>1</sup>Else Kröner-Fresenius-Centre for Nutritional Medicine, Technical University Munich, Freising, <sup>2</sup>Clinical Cooperation Group Nutrigenomics and type 2 diabetes, IEG, Helmholtz Zentrum München, Neuherberg, Germany.

**Background and aims:** The glucokinase (GCK) enzyme is a glucose sensor which is involved in maintaining blood glucose homeostasis. Common variants in the GCK locus have been associated with elevated fasting plasma glucose. The corresponding linkage disequilibrium (LD) block encloses several non-coding SNPs. The aim of this work was to identify a cis-regulatory SNP which might explain the increased risk of elevated fasting plasma glucose at transcriptional level.

**Materials and methods:** NPs located in high LD were bioinformatically analyzed using Genomatix software. Electrophoretic mobility shift assay (EMSA) and reporter gene experiments in the INS1  $\beta$ -cell and the Huh7 hepatocyte cell line were performed to proof the cis-regulatory potential.

**Results:** All SNPs in strong LD ( $R^2 = 0.7$ ; 500 kb) with the GCK tagSNP rs4607517 were bioinformatically analysed. The SNP rs2908289C/T ( $R^2 = 1.0$ ), which is located 4.5 kb upstream of the  $\beta$ -cell specific GCK promoter, was predicted to be cis-regulatory. A differential allele-specific binding of nuclear proteins was shown by EMSA. We proved the cis-regulatory function by reporter gene assays in the INS1  $\beta$ -cell line. The minor T allele revealed a significantly lower luciferase activity compared to the major C allele. In contrast, no allele-specific difference was observed in the Huh7 hepatocyte cell line, pointing to the cell type-specificity in pancreatic  $\beta$ -cells. Moreover, we demonstrated a glucose-dependent regulation of the luciferase constructs in the INS1  $\beta$ -cell line, supporting the physiological relevance of the regulatory element.

**Conclusion:** We identified a novel cis-regulatory SNP in the GCK LD block. The SNP may regulate expression of the endogenous GCK gene in  $\beta$ -cells, and thus confer a higher risk of increased fasting plasma glucose observed in association studies.

### Association between rs2943641 polymorphism near IRS1 locus and incident type 2 diabetes is modified by macronutrient intake and sex

U.C. Ericson<sup>1</sup>, G. Rukh<sup>1</sup>, I. Stojkovic<sup>1</sup>, E. Sonestedt<sup>1</sup>, B. Gullberg<sup>2</sup>, E. Wirfält<sup>2</sup>, M. Orho-Melander<sup>1</sup>;

<sup>1</sup>Diabetes and Cardiovascular disease, Genetic Epidemiology, <sup>2</sup>Nutrition Epidemiology, Department of Clinical Sciences in Malmö, Lund University, Malmö, Sweden.

**Background and aims:** The minor T-allele of rs2943641 near IRS1 has been associated with decreased risk of type-2-diabetes, insulin resistance and adiposity in genome-wide association studies. Dietary intake may influence IRS1 phosphorylation and insulin signaling. Studies have indicated sex-specific associations between IRS1 and adiposity, and between carbohydrate intake and incident type-2-diabetes. We aimed to examine interaction between the IRS1rs2943641 polymorphism and macronutrient intakes on body fat% and incident type-2-diabetes in the Malmö Diet and Cancer cohort, and to investigate if such interaction is sex-specific.

**Materials and methods:** In total 15 227 women and 9 614 men, 45–74 years with dietary data and IRS1 genotypes, and without prevalent diabetes, were included. Dietary data was collected with a modified diet history method. During 12 years follow-up, 1567 incident type-2-diabetes cases were identified.

**Results:** The T-allele associated with lower incidence of type-2-diabetes (P for trend=0.003), and in men, with higher body fat% (P for trend=2×10<sup>-5</sup>). We observed 3-way interaction between sex, IRS1 and carbohydrate intake (P=0.01), as well as between sex, IRS1 and fat intake (P=0.01), on incident type-2-diabetes. Among women the T-allele was only associated with decreased risk in the lower tertiles of carbohydrate intake (P for trend=0.01; P for interaction=0.01). In contrast, among men the T-allele was associated with decreased risk in the lowest tertile of fat intake (P for trend=0.01; P for interaction=0.02).

**Conclusion:** Our results indicate sex-specific interactions between IRS1 and macronutrient intakes on incident type-2-diabetes. The IRS1 T-allele associated with decreased risk of type-2-diabetes in women at low carbohydrate intakes, but in men at low fat intakes.

### Dietary fat intake and the L162V polymorphism at the PPARA locus modulate glycaemia and type 2 diabetes risk in the D.E.S.I.R. prospective study

A. Lamri<sup>1,2</sup>, I. Porchay-Baldérelli<sup>1,2</sup>, N. Emery<sup>1,2</sup>, N. Bellili<sup>1,2</sup>, O. Lantieri<sup>3</sup>, B. Balkau<sup>4,5</sup>, M. Marre<sup>1,2</sup>, F. Fumeron<sup>1,2</sup>, D.E.S.I.R. study group; <sup>1</sup>Inserm U695, Paris, <sup>2</sup>Université Paris Diderot, Paris, <sup>3</sup>Institut inter Régional Pour la Santé (IRSA), La Riche, <sup>4</sup>Inserm U1018, Villejuif, <sup>5</sup>Université Paris-Sud 11, Villejuif, France.

**Background and aims:** PPARα is a transcription factor involved in lipid metabolism and energy homeostasis. The rare allele V of the L162V polymorphism has been associated with an increased risk of conversion from impaired glucose tolerance to type 2 diabetes. The V allele has a lower transcriptional activity than the frequent allele L in low ligand concentration, and a higher transcriptional activity in high ligand concentration, suggesting an interaction between the L162V genotype and dietary fat intake. Our aim was to study the effect of this interaction on glycaemia and the risk of incident type 2 diabetes in a 9-year prospective cohort drawn from the French general population, the D.E.S.I.R. (Data from an Epidemiological Study on the Insulin Resistance Syndrome) study.

**Materials and methods:** A food frequency questionnaire was completed by each participant to assess the intake of main nutrients including dietary fat. Statistical analyses included logistic regression and analysis of covariance with adjustment for confounding variables.

**Results:** Among low fat consumers, type 2 diabetes incidence was higher in V carriers than in LL homozygotes (OR [CI95%] = 3.12 [1.64–5.88] P = 0.0005, P interaction = 0.005). A higher fat intake was associated with an increased type 2 diabetes risk in LL homozygotes (OR=1.30 [1.03–1.63] P = 0.02) but not in V carriers. Similar interaction effects were found on glycaemia and HbA1c during the follow up. There was also an interaction between L162V genotype and fibrate treatment (P = 0.05): fibrates significantly reduced glycaemia in V carriers only (P = 0.005). Conversely, V carriers tended to have a lower glycaemia than LL homozygotes among subjects treated with fibrates (P = 0.06).

**Conclusion:** The L162V polymorphism of PPARA modulates the effects of dietary fat or fibrate treatment on glycaemia and type 2 diabetes risk.

## 290

### TCF7L2 rs7903146 interacts with dietary fibre intake modifying LDL- and total cholesterol levels

G. Hindy, U. Ericson, E. Sonestedt, M. Orho-Melander; Department of Clinical Sciences, Lund University, Malmö, Sweden.

**Background and aims:** The type 2 diabetes (T2D) susceptibility variant TCF7L2 rs7903146 has previously been reported to interact with dietary fibre and whole grain on incidence of T2D. TCF7L2 is expressed in high levels in intestinal cells and may be involved in GLP-1 secretion. Recently, short-chain fatty acids (colonic fermentation products of fibre), were shown to trigger secretion of GLP-1 from colonic cultures *in vitro*. As in some studies TCF7L2 variant has been associated with cholesterol levels and as dietary fibre

has been associated with lower cholesterol levels, we hypothesized that fibre intake level could interact with TCF7L2 variant and modify association between fibre intake, TCF7L2 and cholesterol levels.

**Materials and methods:** From the Malmö Diet and Cancer Cardiovascular (MDCCV) cohort we included 5,069 individuals (aged 45–73 years) without T2D and cardiovascular disease at baseline. The diet data was based on a 7-day food diary, a 168-items diet questionnaire and a 1-h diet-history interview. Fasting total cholesterol (TC), high density lipoprotein cholesterol (HDL), and triglycerides (TG) were measured and low density lipoprotein cholesterol (LDL) was calculated by Friedewald's formula. Linear regression was used to analyse association between TCF7L2 genotype and the different components of lipid profile in tertiles of dietary fibre adjusting for age, sex, and BMI. Interaction between TCF7L2 genotypes and dietary fibre intake level on components of the lipid profile was analysed by introducing a multiplicative factor in addition to both of these variables to the equation with further adjustment for season, dietary method, and total energy intake.

**Results:** The TCF7L2 T-allele did not associate with any component of the lipid profile in MDCCV. After stratification by fibre intake tertiles, the TCF7L2 T-allele associated with significantly higher TC and LDL in the highest fibre intake tertile (beta = 0.10 and 0.023 mmol/L, p = 0.026 and 0.017, respectively). High fibre intake associated with lower TG levels (beta = -0.02 mmol/L, p = 0.02), but not with TC, LDL or HDL in MDCCV. Association between high fibre intake and lower TG was driven by a significant association among CC genotype carriers (p = 0.009) but not among T-allele carriers. In addition, high fibre intake associated with higher TC and LDL levels among TT genotype carriers (p = 0.03 and 0.004, respectively) but not among C-allele carriers. A formal test of interaction between TCF7L2 genotype and tertiles of fibre intake on TC and LDL revealed significant interactions (p = 0.022 and 0.021, respectively). No significant interactions were observed on HDL and TG levels.

**Conclusion:** Our results suggest that the association between dietary fibre intake and TC, LDL and TG levels is dependent on the TCF7L2 genotype; high fibre intake associated with lower TG among CC genotype carriers but with higher TC and LDL among TT genotype carriers. Interaction between fibre intake and TCF7L2 was significant on TC and LDL levels. Although the mechanism of such interaction remains unknown, our results provide some further evidence that the mechanism by which TCF7L2 rs7903146 affects TCF7L2 function may be modified by dietary fibre intake.

### The Krüppel-like factor 6-IVS1-27A (KLF6) polymorphism is associated with more favourable postprandial glucose metabolism in subjects at high risk of type 2 diabetes

G.A. Daniele<sup>1</sup>, H.L. Reeves<sup>2</sup>, L. Agius<sup>3</sup>, M. Gaggini<sup>4</sup>, M. Comassi<sup>1</sup>, R. Miccoli<sup>1</sup>, S. Del Prato<sup>1</sup>, A. Gastaldelli<sup>5</sup>; <sup>1</sup>Department of Endocrinology and Metabolism, Pisa University, Italy, <sup>2</sup>Northern Institute for Cancer Research, Newcastle University, UK, <sup>3</sup>Institute of Cellular Medicine, Newcastle University, UK, <sup>4</sup>Department of Surgery, Pisa University, Italy, <sup>5</sup>Institute of Clinical Physiology, National Research Council, Pisa, Italy.

**Background and aims:** We have previously shown that the KLF6-IVS1-27A polymorphism is associated with better hepatic insulin sensitivity and delayed histological progression of non-alcoholic fatty liver disease (NAFLD). We have proposed that KLF6 acts on glucokinase (GCK) by antagonizing GCKR, its negative regulator in liver. The aim of this study was to evaluate the *in vivo* effects of the KLF6-IVS1-27A polymorphism on postprandial hepatic glucose metabolism.

**Materials and methods:** We studied 35 genotyped subjects (Group 1: 29 wild-type GG and Group 2: 6 carriers of AG allele for the polymorphism, KLF6-IVS1-27A, of KLF6 transcription factor gene) by mixed meal test (MMT) with the use of tracers. All subjects were previously screened for glucose tolerance (OGTT). We evaluated fasting and MMT hepatic glucose production, hepatic insulin resistance index (Hep-IR=EGPxINS), oral glucose absorption, MMT glucose clearance and insulin secretion.

**Results:** All subjects were at high risk for type 2 diabetes (either with family history of type 2 diabetes and/or impaired glucose regulation) but had similar OGTT screening fasting and 2h plasma glucose (5.2±0.6 vs 5.1±0.5 mmol/l and 6.2±2.2 vs 5.6±0.9 mmol/l, mean±SD, GG vs. AG, p=ns). The two groups were similar for age (55±12 vs. 56±14 years, z), BMI (28±4 vs. 26±5, Kg/m<sup>2</sup>), HbA1c (6.0±0.4 vs. 5.9±0.5 %), total cholesterol (10.1±3.4 vs. 10.1±2.1

mmol/l), LDL ( $3.2 \pm 1.3$  vs.  $2.9 \pm 0.7$  mmol/l), HDL cholesterol ( $1.5 \pm 0.3$  vs.  $1.6 \pm 0.5$  mmol/l), triglycerides ( $1.2 \pm 0.9$  vs.  $1.5 \pm 1.3$  mmol/l), creatinine ( $61 \pm 7$  vs.  $61 \pm 15$  micromol/l), (GG vs. AG all  $p = \text{ns}$ ). Fasting Hep\_IR was lower in AG as compared to GG ( $304[171]$  vs  $482[545]$   $\mu\text{mol/min/kg}\cdot\text{pmol/l}$ , median [IQR],  $p < 0.05$ ). During MMT, postprandial glucose profiles were lower in AG carriers than GG group due to better peripheral glucose clearance ( $3.5 \pm 1.7$  vs.  $2.6 \pm 0.8$  ml/kg/min<sup>-1</sup>;  $p < 0.05$ , AG vs GG) since mean postprandial insulin and C-peptide concentrations were similar (mean 0–240 min.:  $291 \pm 193$  vs.  $300 \pm 149$  pmol/l and  $2.7 \pm 1.0$  vs.  $2.5 \pm 0.6$  nmol/l;  $p = \text{ns}$ , AG vs GG) as well as mean EGP ( $2.9 \pm 1.5$  vs.  $3.0 \pm 1.3$   $\mu\text{mol/kg}\cdot\text{min}$ ;  $p = \text{ns}$ , AG vs GG) and post hepatic rate of appearance of ingested glucose ( $15.4 \pm 5.3$  vs.  $13.1 \pm 3.5$   $\mu\text{mol/kg}\cdot\text{min}$   $p = \text{ns}$ ; AG vs GG).

**Conclusion:** AG carriers of KLF6-IVS1-27A polymorphism are characterized by lower postprandial glucose levels, better glucose clearance and hepatic insulin sensitivity.

## 292

### Description of haemoglobin variants among a diabetic population in Portugal

M.G. Barata, Z. Peerally, M.A. Silva, J.F. Raposo;  
Diabetes Portugal, Lisbon, Portugal.

**Background and aims:** Haemoglobin variants are the result of mutations in the globin genes which affect the amino acids of the globin protein. Although hundreds of variants have been identified, only a small number of variants are common and have clinical significance. Haemoglobin variants are inherited in an autosomal recessive manner. Therefore, people who are heterozygous for a given variant are said to have a trait or to be carriers and are usually asymptomatic. Those who are homozygous generally have a disease condition. The accuracy of several glycohaemoglobin measurements methods can be adversely affected by the presence of haemoglobin variant trait. An inaccurate value of HbA<sub>1c</sub> may result either in more aggressive treatment (falsely high) leading to increased episodes of hypoglycaemia, or in a under treatment of diabetes (falsely low). Because of the above, when selecting the assay method, laboratories should take into consideration the characteristics of the population being served. The aim of this study was to identify and evaluate the prevalence of haemoglobin variants in patients from an outpatient diabetes centre in Portugal. And by doing so, confirm the suitability of the equipment present in the laboratory, for the determination of haemoglobin A<sub>1c</sub>.

**Materials and methods:** In 2011, 12213 people with diabetes attended the laboratory at APDP to measure their HbA<sub>1c</sub>. The analyses were performed in a HPLC conventional system, which uses principles of ion-exchange high-performance liquid chromatography (HPLC). In partnership with “Centro Hospitalar e Universitário de Coimbra” in Portugal, the samples with haemoglobin variants were analysed in the conventional system  $\beta$ -thalassaemia short program for identification and then confirmed by isoelectric focusing (IEF) or/and solubility test. If necessary for the determination of uncommon variants, were performed sequencing of  $\alpha$  and  $\beta$  globin chains.

**Results:** This study detected 141 patients with haemoglobin variants. Among this variants, Hb S was the more frequent (76%), followed by Hb D (8%), Hb C (5%) and Hb E (1%). Only 2 samples out of the 12213 had an haemoglobin variant for which the equipment was unable to determine the accurate value of HbA<sub>1c</sub>.

**Conclusion:** In 2011 the prevalence of haemoglobin variants in APDP's laboratory was 1,15%. Moreover the equipment proved to be adequate to the population it serves since for only 0,02% of this population it was unable to measure an accurate value of HbA<sub>1c</sub>. This study also allowed to determine the prevalence of haemoglobin variants by regions (in Portugal) and by country birthplace (in immigrants) of the people who attended APDP in 2011. As expected, there is a marked difference between North and South of Portugal. The immigrants with Africa as birthplace, gave a major contribution to the rise of the prevalence, being these variants essentially of the Hb S type.

## 293

### Detection of haemoglobin variants through the analysis of HbA<sub>1c</sub> by HPLC

J.A. Lopez Medina<sup>1</sup>, M. Cortes Rodriguez<sup>2</sup>, B. Perez Nevot<sup>2</sup>, M. Mayor Reyes<sup>2</sup>, A. Peña Agüera<sup>2</sup>, J.M. Garcia Almeida<sup>1</sup>, F. Tinahones Madueño<sup>1</sup>;  
<sup>1</sup>Endocrinología y Nutrición, <sup>2</sup>Laboratory, Hospital Virgen de la Victoria, Malaga, Spain.

**Introduction:** Measurement of glycated hemoglobin (HbA<sub>1c</sub>) in a single blood sample is considered a reliable measure of long-term metabolic control in diabetic subjects. Determination of glycated hemoglobin is superior to glucose measurements and clinical judgment in evaluating diabetic control. Hemoglobinopathies often interfere with HbA<sub>1c</sub> results. Among the different assays, automated liquid-chromatographic (HPLC) techniques have been widely applied. Hb F and others variants (Hb S, HbC, HbD, HbE, HbJ,...) may interfere with the analysis. Nevertheless, improved HPLC techniques have potential advantages over other methods for determining HbA<sub>1c</sub>.

**Objective:** The objective of our study is to detect haemoglobin variants interfering with haemoglobin A<sub>1c</sub> measurements.

**Materials and Methods:** HbA<sub>1c</sub> measurements were performed on ethylenediamine tetra-acetic acid (EDTA) blood samples using cation-exchange HPLC. Chromatograms of samples run in the months of September to December 2011, were checked by a computer program and visually inspected for abnormal patterns suggesting the presence of hemoglobin variants (additional peaks besides Hemoglobin (Hb) A peak or elevated Hb F peak > 10%). The presence of abnormal patterns on the chromatograms were cross-checked using another cation-exchange HPLC.

**Results:** From 5149 diabetic patients, a total of 18 (0,35%) were identified to have hemoglobin variants: 9 (50%) patients were classified as “unknown variants”; 5 patients elevated Hb F (28%), and 4 (22%) patients heterozygous Hb C.

**Conclusion:** Various factors may affect HbA<sub>1c</sub> measurements according to the assay method used, of which hemoglobin variants are one of them. More than 1000 hemoglobin variants have been identified, with many of them being clinically silent. Therefore, a falsely high or low HbA<sub>1c</sub> value caused by the presence of a clinically silent hemoglobin variant may lead to over- or under-treatment of diabetic patients. Cation-exchange high performance liquid chromatography (HPLC) is one of the methods that is vulnerable to the effect of hemoglobin variants on HbA<sub>1c</sub> measurements. A new software used in our hospital allows the detection of a high number of hemoglobine variants and gives notice to doctors automatically in case this happens. Therefore, the laboratory has considered including the the following statement in the results report as a strategy to adopt: “Possible appearance HbA<sub>1c</sub> variation that can alter the results of HbA<sub>1c</sub>”, thereby alerting the clinician to monitor the diabetic patient; and sending unclassified variants for identification by sequencing, for the physician and patient knowledge.

## PS 004 “Omics” in type 2 diabetes

### Gene expression data from a genome-wide transcriptomics study improve the prediction of type 2 diabetes: KORA S4/F4 cohort

C. Herder<sup>1</sup>, M. Carstensen<sup>1</sup>, S. Landwehr<sup>2</sup>, K. Heim<sup>3</sup>, W. Rathmann<sup>2</sup>, B. Thorand<sup>4</sup>, C. Meisinger<sup>4</sup>, H.-E. Wichmann<sup>5</sup>, S. Martin<sup>6</sup>, H. Finner<sup>2</sup>, K. Strassburger<sup>2</sup>, T. Meitinger<sup>3,7</sup>, M. Roden<sup>1,8</sup>, T. Illig<sup>9,10</sup>, H. Prokisch<sup>3,7</sup>; <sup>1</sup>Institute for Clinical Diabetology, Düsseldorf, <sup>2</sup>Institute for Biometrics and Epidemiology, German Diabetes Center, Düsseldorf, <sup>3</sup>Institute of Human Genetics, Helmholtz Zentrum München, <sup>4</sup>Institute of Epidemiology II, Helmholtz Zentrum München, Neuherberg, <sup>5</sup>Institute of Epidemiology I, Helmholtz Zentrum München, Neuherberg, <sup>6</sup>West-German Centre of Diabetes and Health, Düsseldorf, Germany, <sup>7</sup>Institute of Human Genetics, Technical University Munich, <sup>8</sup>Department of Metabolic Diseases, University Hospital Düsseldorf, <sup>9</sup>Research Unit of Molecular Epidemiology, Helmholtz Zentrum München, Neuherberg, <sup>10</sup>Hannover Unified Biobank, Hannover Medical School, Germany.

**Background and aims:** Risk prediction for type 2 diabetes remains suboptimal although a number of major clinical risk factors are known. Biomarkers from novel ‘omics’ technologies may be useful to improve the prediction of type 2 diabetes over and above established clinical risk factors. Therefore, the aim of this study was to test the hypothesis that mRNA transcript data from peripheral blood can improve the accuracy of current models for the prediction of type 2 diabetes.

**Materials and methods:** Genome-wide gene expression levels in fasting peripheral whole-blood samples were measured using the Illumina HumanHT-12 v3 Expression BeadChip in 513 initially non-diabetic individuals who participated in the population-based KORA Survey S4 (1999–2001) in Augsburg/Germany. Oral glucose tolerance tests (OGTT) were performed in KORA S4 and in the follow-up survey KORA F4 (2006–2008), and 50 individuals with incident type 2 diabetes were identified. Associations between normalised and log2 transformed transcript levels and incident type 2 diabetes were assessed by logistic regression using Storey’s critical values at a nominal false discovery rate of 0.05 for the correction for multiple testing. The area under the receiver-operating characteristic curve (AUC) was used as measure of discrimination in three prediction models.

**Results:** Expression levels of 93 transcripts were associated with the risk for incident type 2 diabetes after adjustment for age, sex and body mass index (BMI). Based on a step-wise selection algorithm, 13 of these transcripts were included in three prediction models. The inclusion of transcripts improved the AUC of a basic model (model 1: age, sex, BMI, former smoking status, current smoking status, hypertension) from 0.784 to 0.951 ( $P=6 \times 10^{-8}$ ), of a clinical model (model 2: model 1 + fasting plasma glucose, HbA1c) from 0.839 to 0.966 ( $P=8 \times 10^{-7}$ ) and of a clinical model + OGTT (model 3: model 2 + 2-hour plasma glucose) from 0.911 to 0.970 ( $P=2 \times 10^{-5}$ ).

**Conclusion:** We found that expression levels of multiple transcripts in peripheral blood are associated with incident type 2 diabetes. The combination of 13 transcripts provided excellent discrimination between incident cases and controls in our cohort. Further studies and external replications are needed to test the robustness of our data.

### Common genetic variants of surfactant protein-D (SP-D) and its gene expression in adipose are linked to obesity and type 2 diabetes

N. Pueyo<sup>1</sup>, F.J. Ortega<sup>1</sup>, J.M. Mercader<sup>2</sup>, J.M. Moreno-Navarrete<sup>1</sup>, S. Bonas<sup>2</sup>, J.I. Rodríguez-Hermosa<sup>3</sup>, G. Pardo<sup>4</sup>, M. Serrano<sup>4</sup>, P. Botas<sup>4</sup>, E. Delgado<sup>4</sup>, W. Ricart<sup>1</sup>, F.J. Tinahones<sup>5</sup>, D. Torrents<sup>2</sup>, J.M. Fernandez-Real<sup>1</sup>;

<sup>1</sup>Hospital of Girona, <sup>2</sup>Joint IRB-BSC program on Computational Biology, Institutació Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, <sup>3</sup>Department of Surgery, Hospital of Girona, <sup>4</sup>Hospital Central de Asturias, Oviedo, <sup>5</sup>Service of Endocrinology and Nutrition, Hospital Clínico Universitario Virgen de Victoria de Malaga, Spain.

**Background:** Surfactant protein-D (SP-D) is a primordial component of the innate immunity system intrinsically linked to metabolic pathways. The association of single nucleotide polymorphisms (SNPs) affecting SP-D with inflammation has been recently reported, but there is virtually no data exam-

ining the relation with insulin resistance and type 2 diabetes (T2D). We also sought to evaluate the expression of this collectin in human omental (OM) adipose tissue and in association with measures of regional inflammation and insulin resistance.

**Methods:** We evaluated a common genetic variant of *SP-D* (rs721917, Met<sup>31</sup>Thr) in a sample of T2D patients and non-diabetic controls ( $n=2,711$ ). This SNP and others within the *SP-D* genomic region were also analyzed in the European Caucasian population, *in silico*, by the Meta-Analyses of Glucose and Insulin-related traits Consortium (MAGIC). In a subset of subjects, Circulating ( $n=1,065$ ) and *SP-D* gene expression ( $n=109$ ) in human OM adipose tissue and isolated fat cells were also analyzed in association with measures of inflammation, obesity and glucose tolerance.

**Results:** Case-control analysis showed the significant association of the SNP rs721917 for *SP-D* with circulating *SP-D* and the risk of T2D. GG carriers for this SNP showed decreased *SP-D* concentrations, fasting glucose, and glycated hemoglobin, and 33% ( $p=0.009$ ) lower risk of T2D, estimated under a recessive model. The significance of differences in fasting glucose between groups remained significant after controlling for origin, age, gender, and circulating *SP-D* concentrations ( $p=0.03$ ). Accordingly, this SNP and other *SP-D* SNPs were associated with quantitative measures of glucose homeostasis, insulin sensitivity, and T2D according to the MAGIC data. On the other hand, *SP-D* expression in OM adipose tissue was significantly decreased in obese subjects with T2D were compared to non-obese and non-T2D individuals ( $-47\%$ ,  $p<0.0001$ ). Indeed, OM *SP-D* gene expression correlated with BMI ( $r=-0.34$ ,  $p<0.0001$ ), percent fat mass ( $r=-0.27$ ,  $p=0.004$ ), and insulin resistance, and was positively associated with insulin receptor substrate 1 ( $r=0.23$ ,  $p=0.02$ ) expression in OM adipose tissue.

**Conclusion:** Current data suggests that *SP-D* gene variants are associated with T2D. On the other hand, *SP-D* expression in OM adipose is inversely associated with measures of obesity and insulin resistance.

### Acute effects of medium-chain saturated fat on postprandial lipaemia, incretins, ghrelin and gene expression in healthy first degree relatives of persons with type 2 diabetes

A. Pietraszek<sup>1</sup>, S. Gregersen<sup>1</sup>, B.L. Langdahl<sup>1</sup>, S.B. Pedersen<sup>1</sup>, J.J. Holst<sup>2</sup>, K. Hermansen<sup>1</sup>;

<sup>1</sup>Department of Medicine and Endocrinology, Aarhus University Hospital,

<sup>2</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, Department of Biomedical Sciences, The Panum Institute, University of Copenhagen, Denmark.

**Background and aims:** Subjects with type 2 diabetes (T2D) and their relatives (REL) have increased risk of cardiovascular disease. Increased postprandial triacylglycerolaemia (PPL), which is influenced by diet, is an independent risk factor for cardiovascular disease. Little is known about the effects of medium-chain saturated fat on PPL and gene expression in REL. The objective of this study is to test the hypothesis that intake of medium-chain saturated fat causes larger PPL response in REL compared to controls (CON) and has a differential impact on circulating incretins and ghrelin, as well as on gene expression in muscle and adipose tissue of REL and CON.

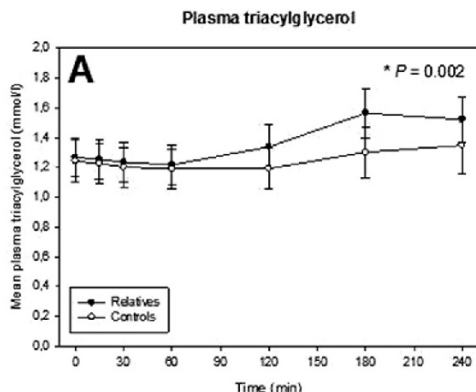

**Materials and methods:** 17 REL and 17 healthy CON with no family history of T2D received a fat-rich meal (79 energy percent from fat) based on medium-chain saturated fat (coconut oil). Plasma concentrations of triacylglycerol, NEFA, insulin, glucose, glucagon-like peptide-1, glucose-dependent insulintropic peptide and ghrelin were measured before the test meal and at regular intervals until 240 min postprandially. Muscle and adipose tissue biopsies were taken at baseline and after the test meal and expression of 31 genes involved in lipid and carbohydrate metabolism was investigated using RT-PCR.

**Results:** Assessed with repeated measurements ANOVA, REL had a higher plasma triacylglycerol response ( $P=0.002$ ) and a tendency towards higher insulin response ( $P=0.100$ ) to the test meal than CON. The responses of plasma glucose, NEFA, glucagon-like peptide-1, glucose-dependent insulintropic peptide and ghrelin did not differ between REL and CON. The genes encoding acyl-CoA long-chain family member 1 (ACSL1), acyl-CoA carboxylase beta (ACACB), hormone-sensitive lipase (LIPE), un-coupling protein 3 (UCP3), solute carrier family 2 (facilitated glucose transporter) member 4 (formerly known as GLUT4), insulin receptor (INSR), phosphoinositide-3-kinase regulatory subunit 1 (PIK3R1), hexokinase 2 (HK2), peroxisome proliferator-activated receptor gamma co-activator 1- alpha (PPARGC1A)

and forkhead box O1 (FOXO1) were up-regulated in response to the meal rich in medium-chain saturated fat in muscle of CON, but not REL.

**Conclusion:** In conclusion, a meal rich in medium-chain saturated fat elicits a larger PPL response, a tendency towards higher insulin response and has a differential impact on gene expression in muscle, but not adipose tissue, of REL compared to CON.

Mean ( $\pm$  standard error of the mean) plasma triacylglycerol in healthy first degree relatives of subjects with type 2 diabetes ( $n=17$ ) and controls ( $n=17$ ) after a meal high in medium-chain saturated fat. Comparison with repeated measurements ANOVA

### Does DNA methylation of PPARGC1A influence insulin action in first degree relatives of patients with type 2 diabetes?

L. Gillberg<sup>1,2</sup>, S. Jacobsen<sup>1,2</sup>, R. Ribel-Madsen<sup>3</sup>, T.W. Boesgaard<sup>2,4</sup>, O. Pedersen<sup>3,4</sup>, T. Hansen<sup>3,5</sup>, A. Vaag<sup>1,6</sup>,

<sup>1</sup>Department of Endocrinology, Rigshospitalet, Copenhagen, <sup>2</sup>Steno Diabetes Center, Gentofte, <sup>3</sup>The Novo Nordisk Foundation Center for Basic Metabolic Research, Faculty of Health Sciences, University of Copenhagen, <sup>4</sup>Hagedorn Research Institute, Gentofte, <sup>5</sup>Faculty of Health Sciences, University of Southern Denmark, Odense, <sup>6</sup>University of Copenhagen, Faculty of Health Sciences, Copenhagen, Denmark.

**Background and aims:** Epigenetics may play a role in the complex pathophysiology of type 2 diabetes (T2D), and increased DNA methylation of the metabolic master regulator peroxisome proliferator-activated receptor gamma coactivator 1 alpha (*PPARGC1A*) has been reported in skeletal muscle and pancreatic islets from T2D patients and in muscle from individuals with increased risk of T2D. Our objective was to investigate DNA methylation and gene expression of *PPARGC1A* in skeletal muscle from 124 Danish first degree relatives (FDR) of T2D patients, and to determine the association with insulin action as well as the influence of family relation.

**Materials and methods:** A total of 124 FDR from 46 different families were included. Skeletal muscle biopsies were excised from *vastus lateralis* and insulin action was assessed by modeling of glucose and insulin profiles during oral glucose tolerance tests. DNA promoter methylation and mRNA expression levels were measured using bisulfite sequencing and quantitative real-time PCR, respectively.

**Results:** The average degree of *PPARGC1A* methylation at four different CpG sites was associated with whole body insulin sensitivity in a paradoxical positive manner ( $\beta=0.37$ ,  $P=0.02$ ), and correlated inversely with fasting insulin levels ( $\beta=-0.89$ ,  $P=0.05$ ). DNA promoter methylation was not associated with *PPARGC1A* gene expression. The heritability estimate of *PPARGC1A* gene expression was high ( $h^2=71\pm25\%$  ( $h^2\pm SE$ ),  $P=0.002$ ), suggesting genetic regulation to play a role. No significant effect of familiarity on DNA methylation was found.

**Conclusion:** Increased DNA methylation of the *PPARGC1A* promoter is unlikely to play a major causal role for the development of insulin resistance in FDR of patients with T2D.

### Common variant in SLC47A1 encoding multidrug and toxin extrusion 1 transporter is associated with stronger effect of metformin on glycaemic control in type 2 diabetes

I. Tkac<sup>1</sup>, M. Javorsky<sup>1</sup>, L. Klimcakova<sup>2</sup>, Z. Schroner<sup>1</sup>, M. Fabianova<sup>1</sup>, E. Babjakova<sup>1</sup>, H. Hermanova<sup>2</sup>;

<sup>1</sup>Department Internal Medicine 4, <sup>2</sup>Department of Medical Biology, Safarik University, Kosice, Slovakia.

**Background and aims:** Pharmacogenetic studies revealed several gene variants associated with response to metformin treatment. Variants in genes encoding organic cationic transporters (OCT) OCT1 (encoded by *SLC22A1*), OCT2 (*SLC22A2*) and multidrug and toxin extrusion 1 (*MATE1*) transporter (*SLC47A1*) were shown to be associated with both the pharmacokinetics and glucose-lowering effect of metformin. None of the primary observations has been replicated in patients with type 2 diabetes so far. The aim of the present study was to investigate possible associations of the mentioned gene variants with glycaemic control in patients with type 2 diabetes.

**Material and methods:** 148 drug-naïve patients with type 2 diabetes (72 males/76 females) were included in the present study. Mean age ( $\pm$ SEM) at initiation of metformin treatment was  $57.5\pm0.9$  years, mean baseline  $HbA_{1c}$  was  $7.64\pm0.09\%$ , and mean metformin dose on-treatment was  $1,400\pm40$  mg/day. Genotyping for *SLC22A1* rs612342 A>C, *SLC22A2* rs316019 G>T and *SLC47A1* rs2289669 G>A variants was done using real-time PCR with subsequent melting-curve analysis. The primary outcome of the study was the reduction in  $HbA_{1c}$  ( $\Delta HbA_{1c}$ ) after 6-month metformin treatment.

**Results:** All examined genotypes followed Hardy-Weinberg equilibrium. *SLC47A1* rs2289669 genotype was significantly associated with  $\Delta HbA_{1c}$  [GG ( $n=45$ ):  $0.61\pm0.15\%$ , GA ( $n=74$ ):  $0.52\pm0.11\%$ , AA ( $n=29$ ):  $1.10\pm0.18\%$  ( $p=0.027$ )]. AA homozygotes had twice as high reduction in  $HbA_{1c}$  as the patients carrying G-allele (GG+GA:  $0.55\pm0.09\%$  vs. AA:  $1.10\pm0.18\%$ ,  $p=0.008$ ). The significance of this difference persisted after adjustment for age, gender, BMI, baseline  $HbA_{1c}$ , metformin dose and creatinine in a general linear model ( $p=0.018$ ). Among the covariates, baseline  $HbA_{1c}$  ( $p<0.001$ ) and metformin dose ( $p=0.025$ ) were also significantly associated with  $\Delta HbA_{1c}$ . The entire model explained more than a half of  $\Delta HbA_{1c}$  variance ( $r^2=0.55$ ), and *SLC47A1* genotype explained 4% of the variance. The examined *SLC22A1* and *SLC22A2* variants were not significantly associated with the response to metformin treatment.

**Conclusion:** The present study showed that approximately 20% of diabetic patients who are homozygous for variant A-allele of *SLC47A1* rs2289669 have double reduction of  $HbA_{1c}$  during first six months of treatment with metformin in comparison with G-allele carriers. This study adds further evidence to personalized treatment of patients with type 2 diabetes.

### Common genetic variation in the FNDC5 locus, encoding the novel muscle-derived 'browning' factor irisin, determines insulin sensitivity

A.A. Böhm<sup>1,2</sup>, M. Scheeler<sup>3</sup>, L. Berti<sup>3</sup>, J. Machann<sup>2,4</sup>, F. Schick<sup>2,4</sup>, F. Machicao<sup>1,2</sup>, N. Stefan<sup>1,2</sup>, A. Fritsche<sup>1,2</sup>, C. Weigert<sup>1,2</sup>, H. Staiger<sup>1,2</sup>, H.-U. Häring<sup>1,2</sup>, M. Hrabě de Angelis<sup>3</sup>;

<sup>1</sup>Department of Internal Medicine IV, Eberhard Karls University Tübingen, <sup>2</sup>Institute for Diabetes Research and Metabolic Diseases of the Helmholtz Centre Munich at the University of Tübingen, <sup>3</sup>Institute of Experimental Genetics, Helmholtz Centre Munich, German Research Centre for Environmental Health, Munich, <sup>4</sup>Department of Diagnostic and Interventional Radiology, Section of Experimental Radiology, Eberhard Karls University Tübingen, Germany.

**Background and aims:** Recently, the novel myokine irisin was described to drive 'browning' of adipose tissue, to increase energy expenditure, and to improve obesity and insulin resistance in high fat-fed mice. Here, we assessed whether common single nucleotide polymorphisms (SNPs) in the locus of *FNDC5* (fibronectin type III domain-containing protein 5), encoding the irisin precursor, contribute to prediabetic phenotypes (overweight, glucose intolerance, insulin resistance, impaired insulin release) in humans.

**Material and methods:** A population of 1,976 individuals was characterized by oral glucose tolerance tests and genotyped for four tagging SNPs covering all common variants (minor allele frequency  $\geq 0.05$ ) in the *FNDC5* locus. In addition, subgroups of 486, 360, and 305 subjects underwent hyperinsu-

linaemic-euglycaemic clamps, magnetic resonance imaging/spectroscopy, and intravenous glucose tolerance tests, respectively. Glucose, insulin, and C-peptide were measured. From 37 participants, muscle biopsies were obtained for the preparation of human myotube cultures.

**Results:** After appropriate adjustment and Bonferroni correction for the number of tested variants, SNPs rs16835198 and rs726344 were associated with in vivo measures of insulin sensitivity ( $p_{\text{Bonferroni}} < 0.0127$ ). Via interrogation of publically available data from the MAGIC consortium, rs726344's effect on insulin sensitivity (fasting insulin) was replicated ( $p_{\text{MAGIC}} = 0.0167$ ,  $p_{\text{meta-analysis}} = 0.0002$ ). Moreover, human myotube *FND5* expression was negatively associated with appropriately adjusted in vivo measures of insulin sensitivity ( $p \leq 0.0465$ ).

**Conclusion:** This study provides evidence that the *FND5* gene, encoding irisin, influences insulin sensitivity in humans. This data translates recent findings in mice to the human situation and establishes a role of irisin in the pathogenesis of human (pre-)diabetes.

#### Association of ACACB rs2268388 G>A polymorphism with metabolic syndrome and type 2 diabetes in a French cohort

F. Fumeron<sup>1,2</sup>, R. Roussel<sup>1,2</sup>, M. Zain<sup>1,2</sup>, A. Lamri<sup>1,2</sup>, N. Bellili<sup>1,2</sup>, N. Emery<sup>1,2</sup>, O. Lantieri<sup>3</sup>, G. Velho<sup>1,2</sup>, B. Balkau<sup>4,5</sup>, M. Marre<sup>1,2</sup>;

<sup>1</sup>UFR de Médecine, INSERM U695, Paris, <sup>2</sup>UFR de Médecine, Univ Paris Diderot, Paris, <sup>3</sup>IRSA, La Riche, <sup>4</sup>INSERM U1018, Villejuif, <sup>5</sup>Univ Paris Sud, Villejuif, France.

**Background and aims:** Fatty acid metabolism is involved in insulin resistance and type 2 diabetes (T2D) pathogenesis. Acetyl-CoA carboxylase  $\beta$ , coded by the ACACB gene, plays a key role in fatty acid synthesis and oxidation pathways. ACACB is expressed at high levels in white adipose tissue. The rs2268388 G>A ACAB polymorphism has been previously associated with obesity and T2D in Spanish women. We investigated the relationship between the rs2268388 G>A ACAB polymorphism and the risk of T2D and/or the metabolic syndrome (MetS) in the DESIR (Data from an Epidemiological Study on the Insulin Resistance Syndrome) cohort, a 9-year prospective study of the French general population.

**Materials and methods:** Over 4000 men and women could be analyzed for the prevalence and the 9 year incidence of T2D and the MetS. The NCEP-ATIII definition of the MetS was used: 1) waist circumference  $> 102/88$  cm for men/women; 2) elevated triglycerides:  $\geq 1.70$  mmol/l; 3) HDL-C:  $\leq 1.03$  mmol/l for men and 1.29 mmol/l for women; 4) blood pressure: systolic blood pressure  $\geq 130$  or diastolic  $\geq 85$  mmHg; 5) fasting glycemia  $\geq 6.1$  mmol/l. The odds ratios to develop T2D and the MetS were assessed separately by logistic regression, adjusting for age, sex, alcohol intake, physical activity, and smoking status, with or without additional adjustment for BMI. The effect of genotype on BMI changes during the follow-up was tested by ANOVA for repeated measures.

**Results:** The A minor allele frequency in the whole DESIR cohort was 0.143. The A allele was associated with a higher T2D incidence (dominant model: OR, 1.51; 95%CI, 1.10–2.09;  $p=0.01$ ). It was also associated with a higher prevalence (OR, 1.29; 95%CI, 1.09–1.53;  $p=0.003$ ) and incidence (OR, 1.48; 95%CI, 1.21–1.82;  $p=0.0002$ ) of MetS. Carriers of the A allele had a significantly higher increase in BMI during the follow-up when compared with GG homozygotes (1.27 vs. 1.10 kg/m<sup>2</sup>,  $p=0.02$ ). After further adjustment on BMI, the genetic association was still significant for MetS (prevalence,  $p=0.002$ ; incidence,  $p=0.0002$ ) but remained only as a trend ( $p=0.07$ ) for T2D.

**Conclusion:** The genetic variation at the ACACB locus has been associated with the susceptibility to type 2 diabetes and metabolic syndrome in a large prospective study. This may be explained only in part by an association with BMI.

### 301

#### Genetic variations in DUSP9 locus and CMIP locus are associated with type 2 diabetes in a Japanese population

M. Imamura<sup>1</sup>, H. Fukuda<sup>2</sup>, M. Iwata<sup>3</sup>, H. Maegawa<sup>4</sup>, H. Watada<sup>5</sup>, H. Hirose<sup>6</sup>, Y. Tanaka<sup>2</sup>, K. Tobe<sup>3</sup>, K. Kaku<sup>7</sup>, A. Kashiwagi<sup>4</sup>, R. Kawamori<sup>5</sup>, S. Maeda<sup>1,5</sup>;

<sup>1</sup>Laboratory for Endocrinology and Metabolism, RIKEN, Center for Genomic Medicine, Yokohama, <sup>2</sup>St. Marianna University School of Medicine, Kawasaki, <sup>3</sup>Toyama University, Toyama, <sup>4</sup>Shiga University of Medical Science, Otsu, <sup>5</sup>Juntendo University, Tokyo, <sup>6</sup>Keio University School of Medicine, Tokyo, <sup>7</sup>Kawasaki Medical School, Kurashiki, Japan.

**Background and aims:** Rs5945326 near DUSP9 on chromosome X was identified as susceptibility locus for type 2 diabetes (T2D) in a meta-analysis of European genome-wide association studies (GWAS). Further, GWAS in South Asian and East Asian populations have identified additional susceptible loci for T2D. To know the roles of these loci in conferring susceptibility to T2D in the Japanese, we examined the association of these variants with T2D in 11,532 Japanese individuals.

**Materials and methods:** We selected 16 single nucleotide polymorphism (SNP) loci, those associations with T2D had not been evaluated in our Japanese population; rs5945326 near DUSP9, 6 SNP loci derived from South Asian GWAS, rs3923113 near GRB14, rs16861329 in ST6GAL1, rs1802295 in VPS26A, rs7178572 in HMG20A, rs2028299 near AP3S2, and rs4812829 in HNF4A, 9 loci from East Asian GWAS including two borderline SNPs, rs7041847 in GLIS3, rs6017317 in FITM2-R3HDM1-HNF4A, rs6467136 in GCC1-PAX4, rs831571 near PSMD6, rs9470794 in ZFAND3, rs3786897 in PEPD, rs1535500 in KCNK16, rs16955379 in CMIP and rs17797882 near WWOX. We genotyped these 16 SNPs for 11,532 Japanese participants (8,449 T2D and 3,083 controls) using multiplex PCR-invader assay. As for rs5945326, females with homozygote and all males were included in the analysis and males were coded as homozygotes. Genotype distribution differences between the case and control groups were analyzed using a logistic regression analysis, and quantitative traits analyses for fasting plasma glucose (FPG), Homeostasis model assessment-Insulin Resistance (HOMA-IR) and HOMA-beta cell function ( $\beta$ ) were performed by multiple linear regression analysis, adjusting age, sex and log-transformed (ln) BMI.

**Results:** Rs5945326-T was significantly associated with T2D and the association reached genome-wide significant level ( $P = 2.21 \times 10^{-8}$ , per homozygote OR = 1.39, 95% CI 1.24 - 1.57). Rs16955379-T was significantly associated with susceptibility to T2D even after Bonferroni's correction ( $P = 2.6 \times 10^{-3}$ , OR = 1.13, 95% CI 1.04 - 1.22). Five SNPs showed nominal association with T2D (rs6017317;  $P = 0.04$ , OR = 1.07, 95% CI 1.003 - 1.15, rs831571;  $P = 7.2 \times 10^{-3}$ , OR = 1.10, 95% CI 1.03-1.18, rs9470794;  $P = 0.029$ , OR = 1.10, 95% CI 1.01-1.20, rs3786897;  $P = 0.011$  OR = 1.09, 95% CI 1.02-1.17, rs178572;  $P = 0.025$  OR = 1.08, 95% CI 1.01-1.16). Remaining 9 SNPs did not show any association with T2D ( $p > 0.05$ ). Rs16955379-T showed modest effects to increase FPG and to reduce HOMA- $\beta$  in control participants (ln FPG;  $P = 0.027$ ,  $\beta = 0.009$ , se = 0.004, ln HOMA- $\beta$ ;  $P = 0.044$ ,  $\beta = -0.055$ , se = 0.027). Other SNPs did not show any association with BMI, FPG, HOMA-IR or HOMA- $\beta$  in controls ( $p > 0.05$ ).

**Conclusion:** We confirmed the association of DUSP9 locus with T2D in the Japanese at genome wide significant level. CMIP locus was also significantly associated with T2D in our Japanese population, although further evaluations for the associations of this SNP as well as remaining 14 loci are required in the Japanese.

#### Mitochondrial DNA depletion and insulin secretion

D.L. Hine<sup>1</sup>, A.E. Brown<sup>1</sup>, L.M. Cree<sup>2</sup>, D. Gunn<sup>3</sup>, L. Brown<sup>3</sup>, P.F. Chinnery<sup>2</sup>, M. Walker<sup>1</sup>;

<sup>1</sup>Diabetes Research Group, Newcastle University, <sup>2</sup>Mitochondrial Research Group, Newcastle University, Newcastle-Upon-Tyne, <sup>3</sup>Discover, Unilever, Bedford, UK.

**Background and aims:** Type 2 diabetes is an age-related condition and is characterised by a progressive decline in insulin secretion. Mitochondria play a key role in energy generation for insulin secretion by way of the electron transport chain. Thirteen polypeptides of the electron transport chain are mitochondrial DNA (mtDNA) encoded. We previously reported a 40–50% age-related decline in mtDNA copy number in human islets isolated from

non-diabetic donors aged from 20 to 80 years. TFAM, mtDNA Transcription Factor A, regulates mtDNA transcription and mtDNA copy number. Using the MIN6 pancreatic beta cell line, we aimed to replicate the percentage decrease in mtDNA copy number that we observed with ageing in human islets, and to explore whether this affected insulin secretion. By targeting TFAM gene expression, we sought to deplete mtDNA copy number in MIN6 cells.

**Materials and methods:** TFAM gene expression was knocked down using siRNA. Seventy two hours post-transfection, cells were stimulated with 3mM or 25mM glucose and subsequent insulin secretion was determined by ELISA. Real-time PCR was used to quantify TFAM knock down, mtDNA copy number, COX1 and Ins1 insulin gene expression. Mitochondrial DNA copy number was measured by comparing the relative expression of mtDNA encoded target gene ND5, with nuclear DNA encoded reference gene GAPDH. TFAM, COX1 and Ins1 insulin gene expression were expressed relative to the reference gene beta-2-microglobulin (B2M). COX1, cytochrome c oxidase subunit 1, is a mtDNA encoded subunit of cytochrome c oxidase (COX, Complex IV) of the electron transport chain. Analyses presented are from 3 separate experiments, each performed in triplicate.

**Results:** Post-transfection, TFAM mRNA levels were depleted by 80% when compared with the scrambled transfection control ( $p < 0.00001$ ). This resulted in a 30–40% reduction in mtDNA levels compared with the control ( $p < 0.01$ ). Following exposure to 25mM glucose, insulin release was decreased in the TFAM knock down cells (mean  $\pm$  SEM:  $4.15 \pm 0.47$  vs  $6.59 \pm 0.57$  ng insulin/ $\mu$ g RNA,  $p < 0.01$ ). The 30–40% decrease in mtDNA observed correlated with a similar 30% decrease in the level of COX1 mRNA compared to the control ( $p = 0.06$ ). We also measured Ins1 insulin gene expression to see whether the decrease in insulin secretion observed was due to a change in Ins1 expression. We found no difference in Ins1 gene expression between TFAM knock down cells and control cells.

**Conclusion:** We found that mtDNA depletion in MIN6 cells to levels seen in human islets with ageing has a direct effect on insulin secretion. This effect on insulin secretion may be due to a defective electron transport chain following a decrease in the mtDNA encoded components. Mitochondrial DNA depletion did not affect insulin gene expression. Strategies to slow islet mtDNA depletion in man could help to preserve insulin secretion and delay the development of Type 2 diabetes.

### 303

#### Copper regulates beta cells function by modulating the expression of cytochrome-c-oxidase and its copper chaperones

C. Mantzur<sup>1</sup>, G. Aharon-Hananel<sup>1</sup>, L. Romero-Afrima<sup>1</sup>, F. Vernea<sup>1</sup>, T. Aouizerat<sup>2</sup>, A. Saada<sup>2</sup>, I. Raz<sup>1</sup>, S. Weksler-Zangen<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, Diabetes Unit, Hadassah University Hospital, Jerusalem, <sup>2</sup>Department of Human Genetics and Metabolic Diseases, Hadassah University Hospital, Jerusalem, Israel.

**Background and aims:** Pancreatic beta cells couple glucose oxidative phosphorylation with insulin secretion. Copper (Cu) is a key element in the catalytic activity of the mitochondria-respiratory chain-enzyme cytochrome c oxidase (COX). Cu delivery to COX subunits COX1 and COX2 depends on Cu-chaperones. However, the mechanism underlying the dysfunction of COX in relation to defective glucose stimulated insulin secretion (GSIS) has not been fully established. The Cohen diabetic sensitive (CDs) rat maintains normoglycaemia on regular diet (RD) but exhibits hyperglycemia when fed a high sucrose copper-deficient diet (HSD). Resistant (CDr) rats fed HSD maintained normoglycaemia. Copper supplementation to the HSD (HSD-Cu) restored beta cell function in hyperglycaemic-CDs rats. Therefore, we studied the molecular mechanism underlying the inhibited GSIS induced by copper deficiency in hyperglycaemic-CDs rats.

**Material and Methods:** Hyperglycaemia was induced in CDs rats by a 30 days exposure to HSD (CDsHSD). Hyperglycaemic-CDsHSD rats were fed HSD-Cu (CDsHSD-Cu) for 20 days. Serum insulin levels were measured after overnight fast and during intravenous glucose tolerance test (IVGTT). The expression (qRT-PCR) of COX1, COX2 and the COX Cu-chaperones Sco1, cox17 and cox11 was evaluated in RNA extracted from islets isolated (beta cells) from these rats. Data was normalized according to the expression in CDr rats fed RD (CDrRD) as controls. COX activity measured in islets homogenate was normalised to citrate-synthase (CS), a mitochondrial enzyme that is not part of the respiratory chain and is not copper dependent.

**Results:** The insulin IVGTT area under the insulin curve (GSIS) was significantly reduced in hyperglycaemic-CDsHSD rats compared to normoglycaemic CDrRD rats (Fig 1A). In parallel, islets-COX activity was

markedly reduced in hyperglycaemic-CDsHSD rats (Fig 1B). These correlated with the decrease in expression of COX1, COX2 and the Cu-chaperones in islets isolated from hyperglycaemic-CDsHSD rats (Fig 1C and D). Dietary Cu supplementation restored the GSIS and islet-COX activity of CDsHSD-Cu rats (Figs 1A and B). Cu supplementation induced a corresponding increase in the expression of the Cu-chaperones but failed to restore the expression of COX1 and COX2 (Figs 1C and D).

**Conclusion:** Our study suggests that dietary Cu modulates the gene expression of COX and its Cu-chaperones thereby affecting the capacity of the  $\beta$ -cells to secrete insulin in response to glucose. The differential effect of Cu supplementation on the expression of the COX subunits and Cu-chaperones implies that the CDs-islets may carry an initial inborn deficit in COX expression that cannot be restored by Cu supplementation. COX activity may therefore be rescued by increasing the expression of the Cu-chaperones transporting Cu to COX.

#### Decreased activity of cytochrome c oxidase in pancreatic islets and lymphocytes of Cohen diabetes rats: a possible biomarker for prediction of type 2 diabetes

L. Romero-Afrima<sup>1</sup>, A. Saada<sup>2</sup>, C. Matzur<sup>1</sup>, G. Aharon-Hananel<sup>1</sup>, T. Aouizerat<sup>2</sup>, A. Jörn<sup>3</sup>, S. Lenzen<sup>4</sup>, I. Raz<sup>1</sup>, S. Weksler-Zangen<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, Diabetes Unit, Hadassah University Hospital, Jerusalem, <sup>2</sup>Department of Human Genetics and Metabolic Diseases, Hadassah University Hospital, Jerusalem, Israel, <sup>3</sup>Centre of Anatomy and Institute of Clinical Biochemistry, Hannover Medical School, <sup>4</sup>Institute of Clinical Biochemistry, Hannover Medical School, Germany.

**Background and aims:** Pancreatic  $\beta$ -cells couple glucose oxidative phosphorylation with insulin secretion. However, a direct link between dysfunction of cytochrome c oxidase (COX), an enzyme in the mitochondrial respiratory chain and defective glucose stimulated insulin secretion (GSIS) has not been fully established. The Cohen diabetic sensitive (CDs) rat exhibit hyperglycemia when fed a high sucrose copper-deficient diet (HSD) but maintain normoglycemia on regular diet (RD).  $\beta$ -cell dysfunction was restored in CDs rats when HSD was supplemented with copper (Cu), a key element for the catalytic activity of COX. Therefore, we investigated the relation between COX activity and GSIS and compared pancreatic islets to lymphocytes. We hypothesize that COX activity could serve as a biomarker for prediction of type 2 diabetes in humans.

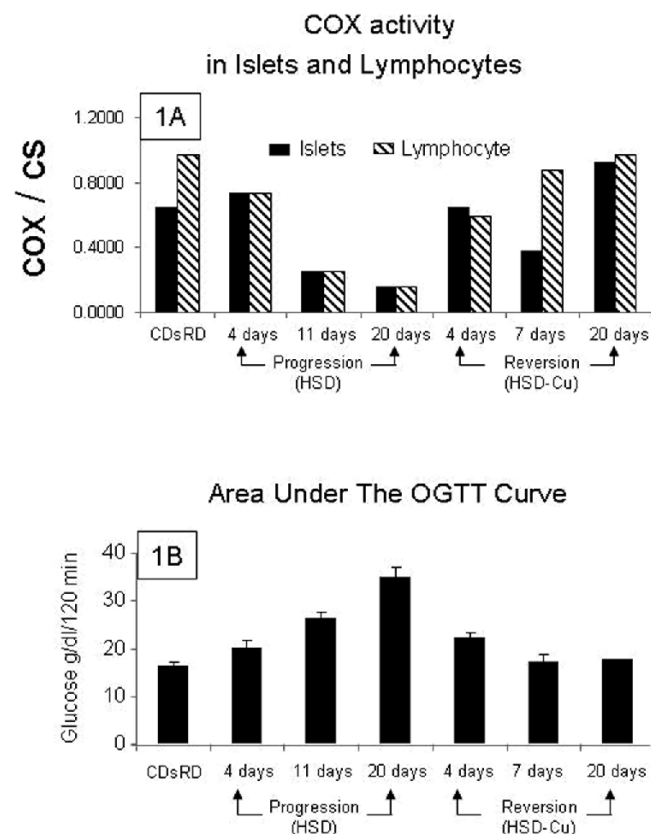

**Material and methods:** CDs rats fed RD (CDsRD) were switched to HSD for 4, 11 and 20 days (Diabetes Progression Study). Hyperglycaemic-CDs rats were fed HSD copper-supplemented (HSD-Cu) for 4, 7, and 20 days (Diabetes Reversion Study). Glucose levels were measured after overnight fast and during oral glucose tolerance test (OGTT). COX activity was measured in homogenates of isolated-islets and lymphocytes. COX activity was normalized to citrate-synthase (CS), a mitochondrial enzyme that is not part of the respiratory chain and is not copper dependent.

**Result:** A parallel change in COX activity was observed in islets and lymphocytes. COX activity decreased in relation to the time on HSD (progression, Fig 1A) in both islets and lymphocytes. Copper supplementation recovered COX activity (reversion, Fig 1A) in relation to the duration on HSD-Cu in

both islets and lymphocytes. The area under the OGTT curve (Fig 1B) increased in relation to the time on HSD (progression) and decreased with time on HSD-Cu (reversion). The increase and decrease in glucose-area under the curve correlated with the reduction and recovery of COX activity in islets and lymphocytes.

**Conclusion:** Our study implies a direct link between low-copper concentrations, reduced COX activity and impaired glucose tolerance in CD rats. The correlation between COX activity in islets and lymphocytes supports COX activity in leukocytes as a biomarker for possible prediction of type 2 diabetes in humans.

### Association of adenovirus 36 infection with obesity and metabolic markers in humans: meta-analysis of observational studies

T. Yamada, K. Hara, T. Kadowaki;

Department of Diabetes and Metabolic Diseases, University of Tokyo, Japan.

**Background and aims:** Several studies have shown that Adenovirus 36 (Ad36) influences the risk of obesity in humans. Clarifying the relationship between Ad36 infection and obesity could lead to more effective approaches for the management of obesity. The objective of this study was to conduct a meta-analysis to confirm the influence of Ad36 infection on obesity and metabolic markers.

**Materials and methods:** We searched MEDLINE and the Cochrane Library for pertinent articles (including their references) published between 1951 and January 28, 2012. Only English language reports of original observational studies were included in this meta-analysis. Data extraction was performed independently by two reviewers. Weighted mean differences (WMDs) and pooled odds ratios (ORs) with 95% confidence intervals (95% CIs) were calculated using the random effects model.

**Results:** Of 225 potentially relevant studies, 10 cross-sectional studies (n=2,870) conformed to the selection criteria. Pooled analysis showed that the WMD for BMI of Ad36 infection compared with non-infection was 3.19 (95% CI: 1.44-4.93; P<0.001). Sensitivity analysis restricted to studies of adults yielded a similar result of 3.18 (95% CI: 0.78-5.57; P=0.009). The increased risk of obesity associated with Ad36 infection was also significant (OR: 1.9; 95% CI: 1.01-3.56; P=0.047). No significant differences were found in relation to total cholesterol (P=0.83), triglycerides (P=0.64), HDL (P=0.69), blood glucose (P=0.08), waist circumference (P=0.09), and systolic blood pressure (P=0.25).

**Conclusion:** Ad36 infection was associated with the risk of obesity and weight gain, but was not associated with abnormal metabolic markers including waist circumference. It suggests that Ad36 infection is more associated with accumulation of subcutaneous fat than that of visceral fat. The relationship between Ad36 and obesity should be assessed by further studies, including well-designed prospective studies, to gain a better understanding of whether Ad36 plays a role in the etiology of human obesity.

### The SHBG genotype rs1799941 is associated with insulin secretion and carotid atherosclerosis, independently of insulin sensitivity, in a healthy European population

F. Bonnet<sup>1</sup>, M. Laville<sup>2</sup>, B. Balkau<sup>3</sup>, E. Ferrannini<sup>4</sup>, M. Walker<sup>5</sup>, for the RISC investigators;

<sup>1</sup>Dept. of Endocrinology-Diabetology, University hospital, Rennes, France,

<sup>2</sup>INSERM U870-INRA 1235, Centre de Recherche en Nutrition Humaine

Rhône-Alpes, Lyon, France, <sup>3</sup>INSERM CESP U1018, Villejuif, France,

<sup>4</sup>University of Pisa, Department of Internal Medicine, Pisa, Italy, <sup>5</sup>University of Newcastle upon Tyne, Glasgow, UK.

**Background and aims:** Studies applying the Mendelian randomization approach suggest that sex hormone-binding globulin (SHBG) may be involved in the pathogenesis of type 2 diabetes. The SHBG A allele at rs1799941 is associated with an increase in plasma SHBG concentration and a reduced risk of type 2 diabetes. However, the underlying mechanisms remain poorly identified. The aim of our study was to explore whether this SHBG variant is associated with insulin secretion and early atherosclerosis after taking into account the degree of insulin sensitivity, in a cohort with a detailed phenotypic characterisation of glucose metabolism and assessment of carotid intima-media thickness (IMT).

**Materials and methods:** We studied 1097 healthy individuals from the RISC study (Relationship between Insulin Sensitivity and Cardiovascular disease) for whom the SHBG genotype was available. All participants had a euglycemic-hyperinsulinemic clamp and an OGTT with determination of various indices of insulin secretion and an ultra sound recording of the carotid arteries, with a centralised evaluation of IMT.

**Results:** Clamp-assessed insulin sensitivity (M/I value) did not differ according to the SHBG rs1799941 genotype. The insulinogenic index [(Insulin<sub>30</sub>

$\frac{\text{min-Insulin}_{0 \text{ min}}}{(\text{Glucose}_{30 \text{ min}} - \text{Glucose}_{0 \text{ min}})}$ ), which represents early phase insulin secretion, was significantly higher in those who carried the SHBG A allele at rs1799941 [ $111.4 \pm 168.8$  for A/G or A/A ( $n=437$ ) vs  $82.6 \pm 192.5$  pmol/mmol for GG genotype ( $n=594$ ),  $p=0.001$ ]. The disposition index (insulinogenic index  $\times$  M/I value), which estimates early insulin secretion after taking into account for insulin sensitivity, was also significantly increased in the presence of the A allele ( $15.3 \pm 25.2$  for A/G or A/A vs  $10.3 \pm 41.4$  I<sup>2</sup>/mmol<sup>2</sup> for the GG genotype,  $p=0.001$ ). The association between the A allele and increased insulin secretion, as assessed with various indices, persisted after adjustment for age, sex, recruitment centre, waist, physical activity, smoking ( $p=0.008$  for the disposition index). These associations were not modified after adjustment for insulin sensitivity (M/I value). In addition, carotid IMT was lower in those who carried the A allele ( $1.92 \pm 0.3$  for A/G or A/A vs  $1.86 \pm 0.3$  mm for GG genotype,  $p=0.001$ ). The A allele was associated with a reduced risk of having an increased intima media thickness (IMT), highest vs lower three quartiles (OR: 0.70; 95% CI: 0.53–0.93,  $p=0.01$ ), independently of conventional risk factors including LDL-c, glycaemia and blood pressure.

**Conclusion:** In a healthy population, the SHBG variant rs1799941 was associated with enhanced  $\beta$ -cell function and a reduced risk of carotid atherosclerosis, independently of insulin sensitivity. The impact of this SHBG variant on cardiovascular outcomes needs to be further studied in diabetic patients.

#### Is air pollution related to metabolic control in type 2 diabetes?

T. Tamayo<sup>1</sup>, W. Rathmann<sup>1</sup>, U. Krämer<sup>2</sup>, D. Sugiri<sup>2</sup>, M. Grabert<sup>3</sup>, R.W. Holl<sup>3</sup>;

<sup>1</sup>Institute of Biometrics and Epidemiology, German Diabetes Center,

<sup>2</sup>Institut für Umweltmedizinische Forschung (IUF), Düsseldorf, <sup>3</sup>Institute for Epidemiology and Medical Biometry, University Ulm, Germany.

**Background and aims:** Air pollution is a major environmental health problem. Evidence is growing that air pollutants are associated with type 2 diabetes (T2DM) risk. Subclinical inflammation may be a mechanism linking air pollution with T2DM. The aim was to investigate if air pollution contributes to higher HbA1c levels in persons with T2DM in an ecological study.

**Material and methods:** Nationwide regional levels (postal areas) of particulate matter with a diameter of 10 $\mu$ m (PM10) were obtained from background monitoring stations in Germany in 2009 (Umweltbundesamt II 4.2). Mean HbA1c (2009) was calculated in 12,058 newly diagnosed T2DM patients (age:  $64 \pm 14$  yrs; males: 53%) throughout Germany (DPV-database). Mean HbA1c stratified for air pollution quartiles (PM10  $\mu$ g/m<sup>3</sup>) was estimated using linear regression modeling adjusting for age, sex, BMI, diabetes duration, geographic region, in/outpatient treatment, and deprivation (low education, migration).

**Results:** Patients exposed to low PM10 concentrations (Q1) had significantly lower levels of HbA1c than in higher quartiles of exposure (Q2–Q4) even after adjustment of established risk factors (Table). The difference between lowest and top quartile was more pronounced in males. In males, HbA1c levels increased with quartile increment of exposure. Similar results were found after further adjusting for antidiabetic treatment (oral agents, insulin).

**Conclusion:** Because of the possibility of residual confounding (socioeconomic status) and the ecological study design, the evidence for a causal association between air pollution and glycemic control T2DM is suggestive but not sufficient. However, in light of the large worldwide number of people exposed to outdoor air pollution this association deserves further experimental and epidemiological investigations. Table: Mean HbA1c (%) (SD) in type 2 diabetes patients stratified by regional particulate matter (PM10) exposure (quartiles)

#### Associations between parental longevity and glucose regulation of the offspring: cross-sectional and longitudinal analyses in the KORA S4/F4 Study

B. Kowall<sup>1</sup>, W. Rathmann<sup>1</sup>, A. Peters<sup>2</sup>, B. Thorand<sup>2</sup>, C. Meisinger<sup>2</sup>;

<sup>1</sup>German Diabetes Center, Düsseldorf, <sup>2</sup>Helmholtz Zentrum München, Neuherberg, Germany.

**Background and aims:** Type 2 diabetes is less prevalent in the offspring of centenarians and nonagenarian siblings. We aimed to assess whether this reduction is also found when less extreme criteria of longevity (lifespan of at least 80 years) are applied, and, therefore, assessed associations between parental longevity and the prevalence of prediabetes and diabetes as well as the incidence of diabetes.

**Materials and methods:** Baseline and 7-year follow-up data of 55–74 year old participants of the population-based German KORA S4/F4 cohort study were used for analyses. Subjects whose parents had died due to traumatic causes were excluded. Diabetes was assessed by validated physician diagnoses or by oral glucose tolerance tests. Using logistic regression models, adjusted odds ratios (OR) and 95% confidence intervals (CI) were calculated for the associations between parental longevity and glucose regulation at baseline (normal glucose tolerance, prediabetes, diabetes), and incident diabetes, respectively.

**Results:** In age- and sex-adjusted models, diabetes prevalence was lower in subjects with one (OR=0.63, 95%-CI: 0.43–0.93), or two long-lived parents (OR=0.46, 95%-CI: 0.25–0.85). For paternal, but not for maternal longevity, an association with the prevalence of prediabetes was observed (OR=0.72, 95%-CI: 0.52–0.99). Incident diabetes was lower in subjects with two than in subjects without long-lived parents, albeit not significantly (OR=0.76, 95%-CI: 0.33–1.72).

**Conclusion:** Prevalence of type 2 diabetes is strongly reduced in subjects whose parents died at age 80 or later. We found an association between paternal longevity and prevalence of prediabetes but no association between parental longevity and incident diabetes.

#### Socioeconomic inequalities in the prevalence of diabetes in Italy

M. Maggini<sup>1</sup>, V. Minardi<sup>1</sup>, V. Possenti<sup>1</sup>, N. Bertozzi<sup>2</sup>, G. Carrozzi<sup>3</sup>,

L. Sampaolo<sup>3</sup>, L. Bolognesi<sup>3</sup>, PASSI coordinating group;

<sup>1</sup>Epidemiology, National Institute of Health, Roma, <sup>2</sup>Local Health Unit, Italy,

<sup>3</sup>Local Health Unit, Modena, Italy.

**Background and aims:** An inverse relationship between socioeconomic status and prevalence of diabetes, as well as for incidence and mortality, has been shown. Furthermore, persons belonging to disadvantaged social classes are more likely to adopt life styles harmful for health. This work is aimed at determine and quantify inequalities in diabetes mellitus for Italian men and women using data of the Italian Behavioural Risk Factor Surveillance System (PASSI).

**Materials and methods:** The PASSI system is a cross-sectional health survey that was begun in 2007 to provide information on the health status of Italian adult population, through the systematic and continuous collection of data on lifestyles, chronic diseases, socio-demographic variables and adherence to preventive programs. 93% of Italian Local Health Units (LHU), covering about 85% of Italy's 18–69-year-old population, participates in the surveillance. LHU residents (18–69 years) are randomly selected, and trained LHU personnel administer telephone interview using standardized questionnaire. A total of 94,996 persons were interviewed in the period 2007–2009. All statistical analyses were conducted weighting for the whole LHU population. Prevalence Rate Ratios (PRR) were estimated through a multivariate Poisson model. All the analyses were performed separately for men and women.

**Results:** Among the population aged 35–69 years, 6.9% reported to have diabetes (men: 7.7%; women: 6.2%). The prevalence increases with worsening of the socioeconomic conditions: for both men and women the prevalence was higher in people with lower education (men: 16.1%; women: 14.4%), and with economical difficulties (men: 11.9%; women: 11.7%). Diabetes prevalence displays significant geographical variations: 6.5% for men in the North, and 9.3 in the South; 4.6% for women in the North and 8.0% in the South. The multivariate model confirmed a significant association of diabetes with age, gender, education, geographical area and economic difficulties. The PRR for a woman with low education (no education/primary school) vs. high edu-

cation (secondary school/university) was 1.9 (CI 95% 1.6–2.3), and PRR for many difficulties vs. none was 2.1 (CI 95% 1.8–2.6). The PRR for men with low education vs. high education was 1.5 (CI 95% 1.3–1.7), and PRR for many difficulties vs. none was 1.5 (CI 95% 1.2–1.8).

**Conclusion:** A strong association was confirmed between prevalence of diabetes and socio-demographic characteristics, including economic level and geographical area. The highest prevalence was observed in Southern Italy and in disadvantaged social groups. Socioeconomic differences in diabetes are larger among women than in men. The large inequalities found for diabetes prevalence require special attention in equity-oriented research and policies. *Supported by: National Institute for Health, Migration and Poverty (NIHMP)*

### 310

#### Validation of indices predicting hepatic steatosis by <sup>1</sup>H-magnetic resonance spectroscopy and their correlation with glucose tolerance

S. Kahl<sup>1</sup>, R. Livingstone<sup>1</sup>, B. Nowotny<sup>1</sup>, B. Klüppelholz<sup>2</sup>, K. Strassburger<sup>2</sup>, J.-H. Hwang<sup>1</sup>, G. Pacini<sup>3</sup>, A. Gastaldelli<sup>4</sup>, G. Giani<sup>2</sup>, M. Roden<sup>1</sup>; <sup>1</sup>Institute for Clinical Diabetology, German Diabetes Center, Düsseldorf, Germany, <sup>2</sup>Institute for Epidemiology, German Diabetes Center, Düsseldorf, Germany, <sup>3</sup>Metabolic Modeling Unit, National Research Council Institute of Biomedical Engineering, Padova, <sup>4</sup>National Research Council Institute of Clinical Physiology, Pisa, Italy.

**Background and aims:** Hepatic steatosis [fatty liver (FL)] is strongly associated with type 2 diabetes. The Fatty Liver Index (FLI) and the Hepatic Steatosis Index (HSI), algorithms based on laboratory and anthropometric parameters assessed in daily routine, are increasingly used to predict FL in clinical studies. Therefore, solid validation is mandatory. Validation of FL has been performed by ultrasound, which provides qualitative but not quantitative assessment of hepatocellular fat content (HCL). Thus, we tested the accuracy of FLI and HSI by validation of the previously established limits of prediction (values <30 exclude; >60 and >36, respectively, define FL) against exact quantification of HCL by <sup>1</sup>H-magnetic resonance spectroscopy (<sup>1</sup>H-MRS) with HCL concentrations exceeding 5.56% indicating FL. As increased HCL has been shown to associate with impairment of glucose tolerance, we analyzed the relationship of FLI and HSI with glycemia and parameters related to insulin sensitivity (OGIS) and  $\beta$ -cell function (insulinogenic index (IGI)). **Materials and methods:** We studied 98 humans without known diabetes (61f/37m; mean age 58 $\pm$ 12 years; body mass index 26 $\pm$ 4 kg/m<sup>2</sup>) before and during a 75 g oral glucose tolerance test (OGTT) and glucose and insulin were determined in 30min intervals. HCL was measured by <sup>1</sup>H-MRS on a 3T magnet (Philips, Netherlands) using stimulated echo acquisition mode (STEAM) sequence and OGIS (ml/min/m<sup>2</sup>) and IGI (pmol<sub>INS</sub>/mmol<sub>GLUC</sub>) were calculated by validated mathematical model analysis from OGTT glucose and insulin values. Correlations were done using Spearman's rank correlation analysis and OGIS was analyzed using linear regression.

**Results:** Employing MRS, 18 out of 98 subjects had FL. HCL ranged from 0.03% to 39.01% with a median of 2.1% [95% confidence intervals: 0.6; 4.2]. FLI and HSI ranged from 1.6 to 91.4 and 23.9 to 51.5 with a median of 23.1 [9.3; 50.5] and 33.3 [29.7;36.4]. Subjects with FL had markedly lower OGIS (p<0.003) and slightly higher IGI (p<0.02) than subjects without FL. HCL correlated with fasting and 2-h glucose (both r=0.29, p<0.004), OGIS (r=-0.46, p<0.0001) and IGI (r=0.22, p<0.04). Using the proposed cut-off limits, FLI yielded a sensitivity (Se) of 78% and a specificity (Sp) of 83%, HSI a Se of 100% and Sp of 75%. Both indices correlated with HCL (r=0.48 and 0.44, both p<0.0001). Furthermore, FLI and HSI positively relate to fasting and 2-h glucose (r=0.37/0.22, p<0.0002/0.03 and r=0.32/0.22, p<0.001/0.03) and negatively relate to OGIS (r=-0.66/-0.55, both p<0.0001), but only HSI related to IGI (r=0.26, p<0.02). Separate regression analyses showed that after adjustment for age, sex and HCL, both indices were inversely and independently associated with OGIS ( $\beta$ =-1.1, p<0.0001 and  $\beta$ =-4.3, p<0.001).

**Conclusion:** Exact quantification of liver fat content revealed that both indices offer reasonable efficacy to detect steatosis. Independently of HCL, FLI and HSI associate with a measure of insulin resistance. Thus, these indices can serve as valuable predictors of hepatic steatosis and insulin resistance in larger clinical studies.

### 311

#### Can liver enzymes predict progression from prediabetes to type 2 diabetes independent of factors associated with the metabolic syndrome in White Europeans and South Asians?

S.A. Mostafa, K. Khunti, D.H. Morris, D. Webb, B.T. Srinivasan, M.J. Davies; Leicester Diabetes Centre, University of Leicester, UK.

**Background and aims:** Liver enzyme activities have been shown to predict incident Type 2 Diabetes (T2DM) in the general population independent of risk factors in the metabolic syndrome. However their role in predicting progression from prediabetes (PDM) to T2DM has not been investigated. Also it is debated whether ALT or GGT is a better predictor and at which level. Both enzymes independently predict T2DM in their normal physiological range, however for ALT this occurs mainly in Europeans and only in the abnormal range for certain ethnic minority groups. As this has never been investigated in South Asians (SA), we analysed a UK multi-ethnic cohort of White Europeans (WE) and SA with PDM undergoing annual re-screening.

**Materials and methods:** Analysis of 735 participants with PDM (impaired glucose tolerance and/or impaired fasting glycaemia using WHO 1999 criteria) detected during the ADDITION-Leicester screening study, who underwent an annual follow up oral glucose tolerance test between 2005 to 2010. People with baseline ALT or GGT levels 3 times the upper reference limit were excluded. Cox proportion models were used to calculate risk of T2DM in WE (n=538) and SA (n=197) for quartiles of baseline ALT and GGT, adjusting for baseline variables: age, sex, BMI, waist circumference, systolic and diastolic BP, creatinine, deprivation level, smoking status, alcohol intake (units/week), triglycerides and HDL. A further model was tested in a sub-sample of 332 participants from the total cohort including additional adjustments for HOMA-IR, hs-CRP and ethnicity.

**Results:** Over a median of 3 years (range 1-5 years), 48 (8.9%) and 34 (17.3%) WE and SA developed T2DM. Compared to lowest ALT quartile<18IU/L (reference), adjusted hazard ratios (HR) predicting DM for groups 18-23, 24-35 and  $\geq$ 36 were 1.2(0.3-5.3), 2.3(0.6-8.6) and 7.0(2.0-24.7, p<0.005) respectively in WE; trend across groups p<0.001. In SA, compared to <16IU/L (reference), quartiles of 16-20, 21-30 and  $\geq$ 31 produced HR of 0.4(0.1-10.4), 0.1(0.03-0.5) and 0.5(0.1-1.5); trend p<0.05. Within ALT quartiles 1 to 4 in South Asians, the % progression to T2DM was 30.2%, 23.1%, 11.3% and 24.5% respectively (p=0.086). For GGT quartiles, compared to <21IU/L, HR for 21-27IU, 28-40 and  $\geq$ 41 were 3.0 (0.6-14.7), 2.7 (0.5-13.1) and 4.8 (1.0-22.7, p<0.05) in WE, trend p=0.201. In SA, the same analysis was not significant. Further modelling on the sub-sample population revealed the significant trends of predicting progression remained after adjustment for hs-CRP, HOMA-IR and ethnicity for ALT (p<0.05) but not GGT.

**Conclusion:** In WE with PDM, ALT was a stronger predictor of progression to T2DM over 3 years than GGT, independent of factors associated with the metabolic syndrome, insulin resistance, sub-clinical inflammation and alcohol intake. Also the risk of DM was significant in the highest ALT quartile which consisted of levels in the 'high-normal' and abnormal range. However in South Asians, increasing ALT and GGT did not appear to be related to higher progression to T2DM.

### 312

#### Liver fat content is associated with impaired glucose profile in Chinese middle-age and elderly population: Shanghai Changfeng Study

X. Li<sup>1</sup>, M. Xia<sup>1</sup>, H. Ma<sup>1</sup>, H. Lin<sup>1</sup>, W. He<sup>2</sup>, X. Gao<sup>1</sup>;

<sup>1</sup>Fudan University, Department of Endocrinology and Metabolism, <sup>2</sup>Fudan University, Department of Ultrasonography, Shanghai, China.

**Background and aims:** Previous studies have shown that people with NAFLD are more than twice as likely to have T2DM, and even moderate elevation in alanine aminotransferase levels, a poor surrogate of fatty liver, was found to be associated with high-normal glucose levels. Moreover, prospective studies suggest people with NAFLD are more likely to have T2DM at all time points of follow-up. In view of several lines of evidence, it suggests that the deposition of fat in the liver might play a role in the development of T2DM. However, It is unknown to what extent liver fat content (LFC) reflects a defect in impaired glucose profiles. Therefore, in the present study we investigated whether LFC measured by quantitative ultrasonography is associated with glycemic abnormalities in people without prior known T2DM, and further to determined to what extent LFC contribute to the adverse glucose profiles.

**Materials and methods:** We conducted a community-based study among 1608 (596 men and 1012 women) residents without prior known diabetes

mellitus at least 45 years old Changfeng community in Shanghai, China. A standard interview (included life style, diseases history through questionnaires), anthropometrics, laboratory parameters (including serum lipid, fasting blood glucose (FBG), 2h postload plasma glucose (PPG) after oral glucose tolerance test were conducted for each participant). The pictures with legible liver and renal were used to calculate LFC. The independence of the associations of prediabetes and diabetes with LFC was assessed by the multivariate logistic regression analysis. Receiver operating characteristic (ROC) curve analyses were used to determine the appropriate cut-off values for LFC to identify pre-diabetes and diabetes. SPSS 17.0 for Windows was used to perform statistical analyses. All statistical tests were two-tailed, and p-values less than 0.05 were considered as significant.

**Results:** By logistic regression analysis, 1% LFC increment independently predicted prediabetes and diabetes (OR 1.034, 1.019–1.050,  $P < 0.001$ ; 1.025, 1.007–1.044,  $P = 0.007$ , respectively) after adjustment for age, sex, ALT, BMI, WHR, SBP, DBP. Cut-off values were calculated for LFC in association with increases in the prevalence of prediabetes and diabetes using ROC analysis (Fig. 1). The areas under the curve were 0.621, 0.635 ( $P < 0.001$ ). The cut-off values for diagnosis of prediabetes and diabetes were 9.99% and 11.54% for LFC respectively. The sensitivity and specificity of the LFC cut-off value for prediabetes and diabetes was 44.8%, 47.7% and 77.6%, 80.4% respectively.

**Conclusion:** These results suggest that LFC is an independent risk factor for prediabetes and diabetes. The optimal cutoffs of LFC for pre-diabetes and diabetes are 9.9% and 11.54% respectively.

Fig. 1 Receiver operating characteristic (ROC) curves for LFC associated with an increased prevalence of pre-diabetes (a) and diabetes (b).

#### Comparison of current BMI and BMI histories to screen for undiagnosed diabetes in Japanese men: Toranomon Hospital Health Management Center Study

S. Yoshizawa<sup>1</sup>, Y. Heianza<sup>1,2</sup>, C. Horikawa<sup>1</sup>, S. Hara<sup>2</sup>, K. Saito<sup>1,2</sup>, S. Kodama<sup>1,2</sup>, S.D. Hsieh<sup>2</sup>, H. Tsuji<sup>2</sup>, N. Yamada<sup>1</sup>, Y. Arase<sup>2</sup>, H. Sone<sup>1,2</sup>

<sup>1</sup>Department of Endocrinology and Metabolism, University of Tsukuba Mito Medical Center, Mito, <sup>2</sup>Health Management Center, Toranomon Hospital, Tokyo, Japan.

**Background and aims:** Evidence has shown that about half of individuals with diabetes remain undiagnosed worldwide. Therefore, screening for undiagnosed diabetes is a major priority. Although the utility of BMI histories in determining risk of developing future diabetes has been studied, we know little about which obesity index would be most effective for screening of undiagnosed diabetes. We therefore aimed to directly compare current BMI and various BMI histories to identify a screening tool for undiagnosed diabetes in Japanese men.

**Materials and methods:** This cross-sectional study included 15143 Japanese men aged 30–75 years without a self-reported history of clinician-diagnosed diabetes. We estimated the probability of having undiagnosed diabetes (diabetes: fasting plasma glucose level of  $\geq 7.0$  mmol/L and/or HbA1c  $\geq 6.5\%$ ) for the following 6 obesity indices: (1) current BMI, (2) BMI at age 20 years ( $BMI_{20y}$ ), (3) lifetime maximum BMI ( $BMI_{max}$ ), (4) BMI change since age 20 years to current BMI ( $BMI\Delta_{20y-cur}$ ), (5) BMI change since age 20 years to maximum BMI ( $BMI\Delta_{20y-max}$ ), and (6) BMI change since maximum to current BMI ( $BMI\Delta_{max-cur}$ ). Logistic regression analysis was performed to investigate odds ratio (ORs) for undiagnosed diabetes using these indices as continuous or categorical variables.

**Results:** Prevalence of undiagnosed diabetes was 4.1% ( $n = 617/15143$ ) among the total subject population. Among the 6 obesity indices,  $BMI_{max}$  (1-SD increment) was most strongly associated with undiagnosed diabetes with an OR of 1.56 [95% CI: 1.45–1.68] after adjustment for age and lifestyle factors. ORs for current BMI or  $BMI\Delta_{20y-max}$  were 1.46 (1.36–1.57) or 1.46 (1.35–1.57), respectively, for undiagnosed diabetes. These 3 BMI histories had a strong association with undiagnosed diabetes compared to the remaining indices (OR 1.19 [1.11–1.29] for  $BMI_{20y}$ , 1.30 [1.21–1.41] for  $BMI\Delta_{20y-cur}$ , and 1.22 [1.14–1.30] for  $BMI\Delta_{max-cur}$ ). When we investigated the combined effect of  $BMI_{max}$  and  $BMI\Delta_{20y-max}$  in identifying undiagnosed diabetes, those in the top tertiles of both  $BMI_{max}$  and  $BMI\Delta_{20y-max}$  had a markedly higher prevalence of undiagnosed diabetes than other individuals (Figure. Panel A). Among obese individuals with current BMI  $\geq 24.5$  kg/m<sup>2</sup> (Panels B, C), having a history of either the top tertile of  $BMI_{max}$  or  $BMI\Delta_{20y-max}$  escalated the likelihood of undiagnosed diabetes. Conversely, in non-obese individuals with a current BMI of  $< 24.5$  kg/m<sup>2</sup>, we observed a substantially low prevalence of undiagnosed diabetes.

**Conclusion:** Our results of direct comparisons of 6 BMI histories showed that both  $BMI_{max}$  and  $BMI\Delta_{20y-max}$  were the most strongly associated with current undiagnosed diabetes. This combination would be a useful tool to screen for diabetic individuals who were unaware of their condition.

### Defining overweight and obesity in 18550 paediatric patients with type 1 diabetes from Germany and Austria - which reference to use?

M. Flechtner-Mors<sup>1</sup>, E.E. Fröhlich-Reiterer<sup>2</sup>, T.M. Kapellen<sup>3</sup>, T. Meissner<sup>4</sup>, J. Rosenbauer<sup>5</sup>, K.O. Schwab<sup>6</sup>, R. Stachow<sup>7</sup>, R.W. Holl<sup>1</sup>, the DPV Initiative and the BMBF competence networks diabetes and obesity;

<sup>1</sup>University Ulm, Germany, <sup>2</sup>Medical University Graz, Austria, <sup>3</sup>University Leipzig, <sup>4</sup>University Düsseldorf, <sup>5</sup>DDZ University Düsseldorf, <sup>6</sup>University Hospital Freiburg, <sup>7</sup>Specialised Clinic for Children and Adolescents, Westerland/Sylt, Germany.

**Background and aims:** Modern intensive insulin therapy / CSII are associated with weight gain, increasing the future cardiovascular risk of the patients. However, the diagnosis of overweight or obesity during childhood depends on the choice of a reference population. Therefore, we compared the rates of overweight and obesity in children and adolescents with type 1 diabetes (T1D) according to four body mass index (BMI) references. In addition, time trend during recent years were examined.

**Material and methods:** The Diabetes and Quality Management System (DPV) is a standardized, longitudinal documentation for patients with diabetes. Over a twelve year period from 2000 (n=10194) to 2011 (n=18550) height and weight of children and adolescents aged between 2 and 18 years, were calculated. Prevalence estimates of overweight and obesity were determined. Three BMI categories were used: non-overweight <90<sup>th</sup> percentile, overweight ≥90<sup>th</sup> - <97<sup>th</sup> percentile and obesity ≥97<sup>th</sup> percentile based on growth curves for age and sex generated by the World Health Organization (WHO), the International Obesity Task Force (IOTF), the German Working Group on Obesity in Childhood and Adolescents (AGA) and the German Health Interview and Examination Survey of Children and Adolescents (KiGGS). Prevalence estimates were adjusted for diabetes duration, age and sex. Statistical analyses were conducted using SAS version 9.2 (SAS Institute, Cary, USA).

**Results:** In children and adolescents with T1D, the prevalence of overweight is highest according to IOTF, followed by WHO, AGA and KiGGS. In contrast, the prevalence of obesity according to WHO is higher compared to AGA, KiGGS and IOTF. More girls are overweight and obese than boys (exception: obesity WHO)(Table, percentages, f=female, m=male). Irrespective of references, the percentage of overweight and obese children and adolescents with T1D increased between 2000 and 2011 (p<0.0001).

BMI category	overweight ≥90 <sup>th</sup> - 97 <sup>th</sup> P.			obese ≥97 <sup>th</sup> P.

### Anthropometric indices of obesity in relation to cardiometabolic disorders in Chinese adults

M. Xu<sup>1</sup>, L. Zhang<sup>1,2</sup>, N. Wang<sup>1</sup>, J. Li<sup>1</sup>, Y. Dong<sup>1,2</sup>;

<sup>1</sup>Qingdao Endocrine & Diabetes Hospital, Qingdao, <sup>2</sup>Weifang Medical University, Weifang, China.

**Background and aims:** Anthropometric indicators such as body mass index (BMI), waist circumference (WC), waist to hip ratio (WHR), and waist to stature ratio (WSR) are used to relate cardiometabolic risk. This study was aimed to identify the optimal anthropometric index in relation to diabetes, hypertension, and dyslipidemia.

**Materials and methods:** We enrolled 15268 Chinese adults aged 18-74 years (M/F: 7018/8250) who participated in a population-based cross-sectional survey conducted in Qingdao, China from 2001-2002. Information on demographic details as well as body weight, height, WC and HC, blood pressure (BP), fasting plasma glucose (FPG), 2-h plasma glucose (2hPG), blood lipid profile were measured. Receiver operating characteristic (ROC) curve was plotted and the optimal cutoff point was identified. Diagnostic accuracy was assessed by the area under the curve (AUC). Multiple logistic regression analysis was used to examine the independent relationship between each anthropometric index and the risk of having cardiometabolic disorders.

**Results:** BMI, WSR, WHR and WC were positively associated with systolic BP (SBP), diastolic BP (DBP), FPG, 2hPG, triglycerides (TG), and low-density lipoprotein cholesterol (LDL-C) in both men and women (P<0.01), but negatively related to high-density lipoprotein cholesterol (HDL-C) (P<0.01). WSR was found to have the largest AUC for diabetes (0.64, 95%CI: 0.62-0.65), hypertension (0.68, 95%CI: 0.67-0.70), and dyslipidemia (0.58, 95%CI: 0.55-0.59) in both genders, followed by WC, BMI, and WHR. The optimal cut-off points of WSR for diabetes, hypertension, and dyslipidemia were 0.52, 0.51, and 0.53, respectively. The odds ratio (OR) of WSR were 1.87 (95%CI: 1.57-2.24) in men and 1.74 (95%CI: 1.54-1.82) in women for having diabetes, 1.80 (95%CI: 1.52-2.11) and 2.43 (95%CI: 2.09-2.82) for hypertension, and 1.40 (95%CI: 1.19-1.65) and 1.31 (95%CI: 1.07-1.61) for dyslipidemia, respectively.

**Conclusion:** WSR might be the optimal anthropometric index in assessing cardiometabolic risk in Chinese adults.

### A habitually higher dietary glycaemic index during puberty is prospectively related to increased risk markers of type 2 diabetes in young adulthood

J. Goletzke<sup>1</sup>, C. Herder<sup>2</sup>, G. Joslowski<sup>1</sup>, K. Bolzenius<sup>1</sup>, T. Remer<sup>1</sup>, S.A. Wudy<sup>3</sup>, W. Rathmann<sup>2</sup>, M. Roden<sup>2,4</sup>, A.E. Buyken<sup>1</sup>;

<sup>1</sup>Research Institute of Child Nutrition, Dortmund, <sup>2</sup>German Diabetes Center, Leibniz Center for Diabetes Research at Heinrich Heine University Düsseldorf, <sup>3</sup>Laboratory for Translational Hormone Analytics in Pediatric Endocrinology, Center of Child and Adolescent Medicine, Justus-Liebig-University, Giessen, <sup>4</sup>Department of Metabolic Diseases, University Hospital Düsseldorf, Heinrich-Heine University, Düsseldorf, Germany.

**Background and aims:** Carbohydrate nutrition during periods of physiological insulin resistance such as puberty may be of particular relevance for future

risk of type 2 diabetes. The aim of this study was to investigate whether the amount (% energy) or the quality (dietary glycemic index, GI; glycemic load, GL; added sugar and fiber intake) of carbohydrates during puberty relates to markers of insulin resistance and fatty liver (steatosis) in young adulthood.

**Materials and methods:** The analysis was based on 208 participants (115 girls and 93 boys) from the DONALD study with at least two 3-day weighed dietary records during puberty (girls: 9–14 years, boys: 10–15 years) and blood samples in young adulthood (18–35 years). Multivariate linear regression models were used to analyze the associations between carbohydrate nutrition and homeostasis model assessment (HOMA-IR) index ( $n=202$ ), the liver enzymes alanine-aminotransferase (ALT), and gamma-glutamyltransferase (GGT) as well as fasting serum triglycerides (TG).

**Results:** A higher dietary GI was prospectively related to greater values of HOMA-IR ( $p$  for trend = 0.03), ALT ( $p$  for trend = 0.03), and GGT ( $p$  for trend = 0.04). After adjustment for sex, age (adult), early life and parental socioeconomic factors as well as protein and fiber intake, predicted HOMA-IR values in energy-adjusted tertiles of GI were 2.41 (95% confidence intervals: 2.17, 2.68), 2.56 (2.31, 2.83), 2.74 (2.46, 3.05). No prospective associations were observed between GI and TG. In contrast to GI, neither the amount of carbohydrates nor GL, added sugar (total or from drinks) or fiber intake were related to any of the analyzed markers. Associations between carbohydrate nutrition and risk markers of type 2 diabetes did not differ by sex ( $p$  for interactions > 0.2).

**Conclusion:** These data indicate that a habitually higher dietary GI during puberty may adversely affect risk markers of type 2 diabetes in young adulthood. Preferred selection of low-GI carbohydrates during puberty could be useful during puberty.

### Lifestyle risk factors and preventable proportion of autoimmune diabetes in adults: 22 years follow-up of the HUNT study

S. Carlsson<sup>1</sup>, V. Grill<sup>2</sup>, K. Midtjell<sup>3</sup>, T. Andersson<sup>1</sup>, B. Rasouli<sup>1</sup>

<sup>1</sup>Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>NTNU Institute of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, <sup>3</sup>HUNT Research Centre, Norwegian University of Science and Technology, Levanger, Norway.

**Background and aims:** Although autoimmune diabetes in adults (AIDA) is prevalent, there is limited data on potential risk factors and the preventive potential of AIDA is unknown. Our aim was to provide a synthesis of available data on lifestyle factors linked to AIDA from the large population-based Nord-Trøndelag Health Study (HUNT), and estimate the proportion of preventable cases if these exposures could be eliminated.

**Materials and methods:** We used data from HUNT, in which adults aged  $\geq 20$  years old were investigated in three consecutive surveys during 1984–2008. Incident cases of diabetes were identified by self-report and subjects with onset age  $\geq 35$  years were classified as type 2 diabetes if they were anti-GAD negative ( $n=2244$ ) and as having autoimmune diabetes if they were anti-GAD positive ( $n=164$ ). Hazard ratios (HR) associated with lifestyle factors, adjusted for potential confounders were estimated by Cox proportion hazards regression models. Population attributable risks (PAR) was estimated for combinations of lifestyle factors, with the lowest risk level as the referent.

**Results:** In multivariate survival analysis, the following factors were associated with AIDA: overweight (HR=2.26, 95 % CI=1.31–3.88), physical inactivity (HR=3.51 95 % CI=1.39–8.88, smoking (HR=0.56 95 % CI=0.34–0.91), moderate alcohol consumption (HR= 0.36, 95 % CI=0.13–0.97), low psychological wellbeing (HR=1.65 95 % CI=0.98–2.79), and family history of diabetes (HR=3.19 95 % CI=2.15–4.74). Similar findings were seen for type 2 diabetes, except for smoking which was associated with an increased risk (HR1.39, 95 % CI 1.07–1.77). Subjects with BMI, physical activity level, psychosocial well-being, and alcohol use in the low risk group had HR for AIDA of 0.16, 95% CI=0.10–0.28 with PAR estimated at 72 % (0.6–93%) with low BMI as the most important protective factor. Corresponding estimates for type 2 diabetes were 0.26, 95% CI=0.6–1.05, PAR, 82% (70–89%).

**Conclusion:** Our findings indicate that the vast majority of AIDA cases are preventable by modification of common lifestyle factors such as weight reduction and physical activity, and that AIDA is similar to type 2 diabetes in this respect.

**Table:** Risk of incident of type 2 and autoimmune diabetes and population attributable risk according to low-risk lifestyle factors.

No. of low-risk lifestyle factors†	No. Cases Exposed/non-exposed (n/n)	Participants in low risk group/all other not in low risk group (n%)	HR* (95% CI)	Population attributable risk ‡ (95% CI), %
<b>Type 2 diabetes</b>				
2 factors in low-risk category (physically active, and alcohol use $\leq 1$ time/ during 2 weeks)	255/1370	16/90 (24.32%) 51/883 (25.88)	0.86 (0.75–0.99)	11 (3–20)
3 factors in low-risk category (2 above plus no heavy smoking)	212/1213	15/151 (23.16%) 53/222 (77.81)	0.87 (0.70–0.96)	14 (3–24)
4 factors in low-risk category (3 above plus without sleep disturbances and low psychosocial well-being)	136/1286	10/771 (15.75%) 57/602 (94.25)	0.78 (0.55–0.94)	19 (5–31)
5 factors in low-risk category (4 above plus BMI $< 25$ )	14/1411	5/783 (8.46%) 62/990 (91.54)	0.16 (0.10–0.28)	82 (70–89)
<b>Autoimmune diabetes in adults</b>				
2 factors in low-risk category (physically active, and alcohol use $\leq 1$ time/ during 2 weeks)	17/98	16/966 (23.93%) 5/969 (26.06)	0.69 (0.40–1.19)	25 (0.70–53)

### A low level of cardiorespiratory fitness during college-age is a precursor of adult-onset diabetes mellitus

Y. Someya<sup>1</sup>, S. Kawai<sup>1</sup>, N. Saga<sup>1</sup>, Y. Kohmura<sup>1</sup>, K. Aoki<sup>1</sup>, E. Marui<sup>2</sup>, H. Daida<sup>3</sup>

<sup>1</sup>School of Health and Sports Science, Juntendo University, Chiba,

<sup>2</sup>Department of Public Health, Juntendo University, Tokyo, <sup>3</sup>Department of Cardiovascular Medicine, Juntendo University, Tokyo, Japan.

**Background and aims:** In recent years, the occurrence of diabetes has increased greatly in Asian countries. There has also been a rapid growth in diabetes in Japan, which is now one of the nations most affected by the worldwide diabetes epidemic. Type 1 diabetes is rare in Japan, with type 2 diabetes predominating in both adults and children. In European-derived populations, overweight and obesity are established causes of diabetes. However, many Japanese diabetics are not obese. An association between physical fitness during college-age and adult-onset diabetes mellitus has not been demonstrated. This study therefore examined the relationship between physical fitness in college-age students and development of adult-onset diabetes in Japanese men.

**Materials and methods:** From 2009 to 2011, we mailed follow-up questionnaires to former students of Juntendo University, with questions regarding the occurrence of doctor-diagnosed adult-onset diabetes mellitus and their lifestyle. The incidence rate of diabetes mellitus during the follow-up period was compared with stored data of a physical fitness test carried out at college (Japanese national physical fitness test: 50 meter dash, running broad jump, pull-ups, hand ball throw, and 1,500 meter endurance run).

**Results:** The responders who had graduated from Juntendo University between 1975 and 1991 included 577 men, 23 (4%) of whom had developed adult-onset diabetes. Mean age was  $20 \pm 2$  years at the college physical fitness test and  $48 \pm 4$  years at the time of the follow-up questionnaire. The subjects with diabetes had increased weight and waistline at the time of the questionnaire (diabetics vs. non-diabetic former students: weight  $77.9 \pm 13.4$  vs.  $72.0 \pm 9.6$  kg, waistline  $89.6 \pm 9.4$  vs.  $83.6 \pm 6.7$  cm), with their gross physical fitness test score and 1,500 meter endurance run (cardiorespiratory fitness level) at college-age being lower than in the non-diabetic former students (diabetics vs. non-diabetic former students: gross physical fitness test score  $63.9 \pm 12.8$  vs.  $57.0 \pm 12.8$  points, 1,500 meter endurance run time  $325.8 \pm 32.5$  vs.  $345.3 \pm 34.8$  seconds). A Cox proportional hazards model across quartiles of cardio-respiratory fitness level (lowest to highest), age, and weight gain since the college physical fitness test until the time of the questionnaire showed the adjusted relative risks for developing adult-onset diabetes mellitus were 1.00 (reference), 0.54 (95% CI: 0.20–1.49), 0.04 (0.05–0.95), and 0.03 (0.07–0.90), respectively ( $p < 0.05$  for trend).

**Conclusion:** These results indicate that a low cardiorespiratory fitness level during college-age may be an important risk factor for the development of adult-onset diabetes in Japanese men.

## 319

**Leisure-time physical activity is a significant predictor for total mortality and stroke among Japanese patients with type 2 diabetes: the Japan Diabetes Complications Study**H. Sone<sup>1</sup>, S. Tanaka<sup>2</sup>, S. Tanaka<sup>2</sup>, S. Suzuki<sup>3</sup>, H. Seino<sup>3</sup>, A. Sato<sup>4</sup>, A. Araki<sup>5</sup>, S. Ishibashi<sup>6</sup>, Y. Ohashi<sup>7</sup>, Y. Akanuma<sup>8</sup>, N. Yamada<sup>1</sup>;<sup>1</sup>University of Tsukuba, Ibaraki, <sup>2</sup>Kyoto University, <sup>3</sup>Ohta General Hospital, Fukushima, <sup>4</sup>Tokyo Women's Medical University, <sup>5</sup>Tokyo Metropolitan Geriatric Hospital, <sup>6</sup>Jichi Medical College, Tochigi, <sup>7</sup>University of Tokyo,<sup>8</sup>Institute for Adult Diseases Asahi Life Foundation, Tokyo, Japan.

**Background and aims:** Although physical activity is reportedly associated with mortality and cardiovascular disease among patients with diabetes, only one study has determined both mortality and cardiovascular events simultaneously, so it is still unclear how physical activity exerts its effect on reducing mortality among diabetic patients. Furthermore, no study has examined the relationship between cardiovascular disease and physical activity among Asian diabetic patients despite the fact that Asian patients account for more than 60% of the world's diabetic population. The aim of this study was to clarify the association between leisure-time physical activity (LTPA), which accounts for an important part of exercise therapy for diabetic subjects, and cardiovascular events and total mortality in a nationwide cohort of Japanese diabetic patients.

**Subjects and methods:** In total, 1702 eligible patients with type 2 diabetes (mean age, 58.5 y; 47% women) from 59 institutes were followed for a median period of 8.05 years. A comprehensive lifestyle survey including LTPA and occupation was carried out using standardized questionnaires. Outcomes were the occurrence of coronary heart disease (CHD) or stroke, and total mortality. The adjusted hazard ratio (HR) and 95% confidence interval (CI) was calculated by Cox regression analysis.

**Results:** A significant reduction in HR among patients in the top ( $\geq 15.4$  METs-hr/week) vs. the bottom ( $< 3.7$  METs-hr/week) tertile of LTPA, adjusted by age, sex and diabetes duration, was observed for stroke (HR 0.55, 95%CI 0.32–0.94) and total mortality (0.49, 0.26–0.91) but not in CHD (0.77, 0.48–1.25). The HR for stroke became nonsignificant after adjustment for clinical variables comprising typical cardiovascular risk factors. The significant reduction in total mortality due to LTPA was independent of lifestyle or clinical variables, and was not, at least mainly, attributed to reduced cardiovascular disease.

**Conclusion:** Among Japanese subjects with type 2 diabetes, an LTPA of more than 15.4 METs-hr/week was associated with a significantly lower risk of stroke through ameliorating combinations of cardiovascular risk factors. It was also associated with a significant reduction in total mortality but was independent of cardiovascular risk factors or events. These findings, which imply differences from Western diabetic populations, should be considered for the clinical management of East Asians with diabetes.

## 320

**Smoking is associated with reduced risk of autoimmune diabetes in adults contrasting with increased risk of type 2 diabetes: a 22-year follow-up of the HUNT study**B. Rasouli<sup>1</sup>, A. Ahlbom<sup>1</sup>, T. Andersson<sup>1</sup>, V. Grill<sup>2</sup>, K. Midtjell<sup>3</sup>, S. Carlsson<sup>1</sup>;<sup>1</sup>Department of Epidemiology, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden, <sup>2</sup>NTNU Institute of Cancer Research and Molecular Medicine, Norwegian University of Science and Technology, Levanger, Norway, <sup>3</sup>HUNT Research Centre, Department of Community Medicine and General Practice, Norwegian University of Science and Technology, Levanger, Norway.

**Background and aims:** Smoking has been associated with an increased risk of type 2 diabetes but the influence on autoimmune diabetes is not clear. We aimed to investigate the association between smoking habits and risks of autoimmune diabetes in adults and type 2 diabetes.

**Materials and methods:** For this prospective cohort study we used data from the three surveys of the Helseundersøkelser in Nord Trøndelag (HUNT) study, spanning 1984 to 2008 and including a cohort of 90,819 participants aged  $\geq 20$  years old. Eligible population for the present study recruited from subjects who were free of diabetes at baseline with complete information regarding smoking habits, age and sex, they followed up for incidence of type 2 diabetes or autoimmune diabetes. Incident cases of diabetes were identified by questionnaire and classified as type 2 diabetes (n=1860) and autoimmune diabetes (n=140) based on anti-GAD and age at onset of diabetes. Hazard

ratios (HR) adjusted for age, sex, BMI and education were estimated by Cox proportion hazards regression models.

**Results:** The risk of autoimmune diabetes was reduced by 48% (HR=0.52, 95% confidence intervals, CI=0.30–0.89) in current smokers and 58% in heavy smokers (HR for  $\geq 20$  cigarettes/day=0.42, 95% CI=0.18–0.98). The reduced risk was associated with number of pack years (HR for  $\geq 13$  pack-years= 0.43, 95% CI 0.23–0.82). Heavy smoking was associated with lower levels of anti-GAD (p=0.001) and higher levels of C-peptide (964.22 vs. 886.15 pmol/l, p=0.03). In contrast, smoking was associated with an increased risk of type 2 diabetes, a risk which was however restricted to overweight men (HR for current smoking= 1.33, 95% CI=1.10–1.61; HR for  $\geq 20$  cigarettes/day=1.70, 95% CI=1.38–2.10; and HR for  $\geq 13$  pack-years=1.57, 95% CI=1.31–1.90). Attributable proportion of type 2 diabetes due to an interaction between overweight and heavy smoking was estimated at 0.40 (95% CI=0.23–0.57).

**Conclusion:** Smoking was associated with a reduced risk of autoimmune diabetes which appears linked to immunosuppression and anti-inflammatory effects of nicotine. In contrast, smoking increases risk of type 2 diabetes risk in overweight men, and overweight and smoking likely interact to induce type 2 diabetes.

### Entred-Ado study: health, education and risk behaviours of adolescents with diabetes

I. Milovanovic<sup>1</sup>, M. Chantry<sup>2</sup>, I. Romon<sup>3</sup>, C. Druet<sup>3</sup>, A. Fagot-Campagna<sup>3</sup>, C. Levy-Marchal<sup>1</sup>;

<sup>1</sup>INSERM-CIE05, Paris, <sup>2</sup>Caisse Nationale d'Assurance Maladie des Travailleurs Salariés, Paris, <sup>3</sup>Institut de Veille Sanitaire, Saint-Maurice, France.

**Background and aims:** The adolescence is a critical moment for diabetic patients representing a period of potential low adherence and poor metabolic control. The aim of present study was to describe the health status, treatment and quality of care of adolescents with diabetes in France and to study educational level, risk-taking behaviors, and quality of life of those young patients.

**Materials and methods:** A 7 % random selection from all the diabetic patients, aged 11–18 years, covered by the French Social Security identified 554 eligible diabetic adolescents. The rate of participation was 51 %. A specifically developed telephone questionnaire was used covering the following topics: health and diabetes, education, risk behaviors and quality of life. These 283 adolescents with diabetes were compared to 115 classmates.

**Results:** Of all responding adolescents 98% had type 1 diabetes. Adolescents younger or older than 16.5 years ( $n = 139$  vs.  $n = 144$ ), were not statistically different in terms of treatment (2 injections: 7% vs. 9%; multi-injections: 67% vs. 75%; pump: 26% vs. 16%;  $p=0.4$ ), HbA1c ( $8.2 \pm 1.4$  vs.  $8.7 \pm 1.9$ ;  $p=0.08$ ), frequency of DKA (6% vs. 11%;  $p=0.1$ ; median = 1/yr) and severe hypoglycemia (9% vs. 4%;  $p=0.1$ ; median = 1/yr). Glycemic control was not influenced by the insulin regimen (2 injections  $8.3 \pm 0.5\%$  HbA1c; multi-injections:  $8.6 \pm 0.1\%$  HbA1c; pump:  $8.3 \pm 0.3\%$  HbA1c;  $p=0.5$ ) whereas HBGM was significantly different between the regimens. 90 % of the adolescents were under hospital care (4 visits /yr). Compared to 115 control adolescents, the rate of school grade repetition was higher (43% vs. 30%;  $p=0.03$ ) and the average school note was lower at adolescents with diabetes (12–20/20: 53% vs. 66%;  $p=0.03$ ). Moreover the rate of absenteeism was higher in the diabetic group with 56% of diabetic adolescents claiming that they were absent from school from time to time and more than 10 % feeling that they were frequently absent from school, comparing with 32% and 4% respectively among their healthy classmates ( $p<0.01$ ). There was no significant difference between adolescents with diabetes and their controls in percentage of adolescents having experienced at least once smoking (39% vs. 41%;  $p=0.8$ ), alcohol (52% vs. 60%;  $p=0.2$ ) or cannabis (14% vs. 17%;  $p=0.4$ ), but these risk behaviors were more regular in the control group. The quality of life of diabetic adolescents assessed by PedsQL questionnaire did not differ in health and emotions from controls, while the study score was lower ( $67 \pm 19$  vs.  $72 \pm 16$ ;  $p=0.01$ ) and the relational score higher ( $87 \pm 13$  vs.  $83 \pm 14$ ;  $p=0.01$ ).

**Conclusion:** This is the first French study in the general population being focused on adolescents with diabetes. Glycemic control is at similar level as in other large European studies, but above the recommendations. A modest but significant impact of diabetes on school performances was identified, not often pointed in the studies in adolescents.

322

### Are disordered eating behaviours more frequent in children and adolescents with type 1 diabetes? A comparison with a population-based sample from Germany

C. Bächle<sup>1</sup>, K. Castillo<sup>1</sup>, K. Straßburger<sup>1</sup>, A. Stahl<sup>1</sup>, T. Meissner<sup>2</sup>, R.W. Holl<sup>3</sup>, G. Giani<sup>1</sup>, J. Rosenbauer<sup>1</sup>, in cooperation with the German Pediatric Surveillance Unit (ESPED), the DPV-Science Initiative, and the Competence Network Diabetes mellitus;

<sup>1</sup>Institute of Biometrics and Epidemiology, German Diabetes Center, Düsseldorf, <sup>2</sup>University Children's Hospital Düsseldorf, <sup>3</sup>Institute of Epidemiology and Medical Biometry, University of Ulm, Germany.

**Background and aims:** Despite modern therapeutic regimens youths with type 1 diabetes (T1DM) may be at increased risk of mental and behavioural disorders including eating disorders. The aim of this study was to compare the prevalence of disturbed eating behaviours in children and adolescents with T1DM and their peers from the general population.

**Materials and methods:** Data of 629 T1DM patients from a population-based, nationwide survey (54.1% male, age 15.3 (SD 1.7) years, 48.7 (SD 0.5) % continuous subcutaneous insulin infusion) with early-onset diabetes (0–4 years) and at least 10 years diabetes duration (12.5 (SD 1.6) years) were compared with 6813 participants from the representative German KiGGS study (51.3% male, age 14.6 (SD 2.0) years). The SCOFF questionnaire was applied as screening instrument to identify subjects with suspicious eating behaviours. The gender-stratified comparison between the two groups was conducted by regression analyses adjusting for socio-demographic covariates. A sensitivity analysis was accomplished excluding SCOFF question 5 (Would you say food dominates your life?).

**Results:** 31.2% (11.7%) of the female (male) T1DM patients and 28.9% (15.2%) of the female (male) subjects of the comparison group were SCOFF positive ( $p>0.05$ ). The risk of patients with early-onset, long-lasting T1DM for symptoms of eating disorders was 5% higher for female, but 7% lower for male patients, yet not significantly different from the comparison group (adjusted OR female: 1.05, 95%-CI: 0.78–1.42; male: 0.93, 95%-CI: 0.62–1.38). Excluding question 5, the adjusted OR dropped to 0.78 for female (95%-CI: 0.54–1.12) and 0.37 for male patients (95%-CI: 0.17–0.77) indicating a lower prevalence of abnormal scores in male patients with T1DM.

**Conclusion:** Today, children and adolescents with early-onset T1DM do not seem to be more frequently affected by disturbed eating behaviours than their peers. The indicated lower risk may be explained by increased awareness of treating physicians.

### Epidemic of DKA in Colorado: An indicator of childhood poverty and poor access to care

A. Rewers, M. Rewers;

The Barbara Davis Center for Childhood Diabetes, University of Colorado, Aurora, USA.

**Background and aims:** The frequency of diabetic ketoacidosis (DKA) at diagnosis is determined by community awareness of diabetes, access to medical care, and its quality. DKA rates have decreased or remained stable in most developed countries, during the past 20 years. This study examined the frequency of DKA at diagnosis and its predictors in Colorado children, during 1998–2010.

**Materials and methods:** Electronic patient record database of the Barbara Davis Center for Childhood Diabetes in Denver, ascertained 3257 children diagnosed with type 1 diabetes (T1D) in Colorado, during 1998–2010. Over 80% of children with diabetes in Colorado are seen at the Center within two years after diagnosis. T1D was present in 2953 (91%) of the children, using the American Diabetes Association criteria (the Center routinely tests all new patients for autoantibodies to insulin, GAD65 and IA-2, and more recently for ZnT8). Patients with type 2 diabetes ( $n=181$ , including 9 with DKA), diabetes secondary to other conditions, e.g., CF, steroid treatment ( $n=91$ , one with DKA) and those with monogenic or undefined type of diabetes ( $n=32$ , none with DKA) were excluded from further analyses. Medical records of all patients were reviewed for DKA at diagnosis (venous  $\text{pH}<7.3$  or bicarbonate  $<15$  mEq/l, in presence of hyperglycemia and ketosis). Data were insufficient to rule in/out DKA in 148 (5%) of T1D patients.

**Results:** The age-adjusted prevalence of Colorado children presenting in DKA has increased from 31.6% in 1998–2000 to an average of 44.3% during 2001–2010 ( $p=0.001$ ) [figure]. In multivariate logistic regression, younger age, low socioeconomic status and uninsurance were associated with DKA. On the population basis, this dramatic increase in severity of manifestation could be partially explained by a higher observed proportion of uninsured patients among children diagnosed more recently. The increase in DKA correlated ( $r=0.72$ ,  $p<0.02$ ) with the poverty rate in Colorado children (annual income below \$22,050 per family with two children, in 2010 dollars). The poverty rate has increased gradually from 10% (1998–2001) to 17% (2010) [figure].

**Conclusion:** The apparent epidemic of DKA in Colorado children over the past 10 years, despite raising community awareness of diabetes symptoms, points to problems with access to and quality of primary care. The rates of DKA in Colorado children, previously declining, are now twice as high as those in Europe. Our data support previous suggestions that rates of DKA at diagnosis correlate with poverty and income inequality.

## Prevalence of DKA at onset and poverty in Colorado children

## 324

## Age-period-cohort analysis of diabetes incidence time trends among 0 to 14 years-old children in Sardinia (Italy), 1989-2009

G. Bruno<sup>1</sup>, M. Maule<sup>2</sup>, F. Merletti<sup>2</sup>, A. Ledda<sup>3</sup>, V. Cau<sup>3</sup>, M. Songini<sup>3</sup>, Sardinian Group for Epidemiology of Type 1 Diabetes;

<sup>1</sup>Dept. Internal Medicine, Torino, <sup>2</sup>Cancer Epidemiology Unit, Torino,

<sup>3</sup>Diabetes Unit, Cagliari, Italy.

**Background and aims:** Sardinia is the second largest Mediterranean island and is characterized by one of the highest incidence rates of Type I diabetes in the world. Our aim was to analyze incidence time trends of childhood-onset Type I diabetes in Sardinia in period 1989-2009 using an age-period-cohort approach.

**Materials and methods:** Data on incident cases was obtained from the Sardinian Registry of Type I diabetes. Poisson regression models were used to estimate the effects of sex, age (5 three-year age groups: 0-2, ..., 12-14), calendar time (7 three-year periods: 1989-91, ..., 2007-09) and birth cohorts (11 six-year birth cohorts: 1974-79, ..., 2004-09). The models, hierarchically ordered, were compared by the likelihood ratio test.

**Results:** In 1989-2009, 2371 incident cases (1380 boys and 991 girls) were identified among children aged 0-14 years. Incidence rate was 44.85 cases per 100,000 person-years, (95% CI 43.08-46.69), with significantly lower risk in girls (38.70; 95% CI: 36.37-41.19) than in boys (50.63; 95% CI: 48.03-53.37). In regression analysis, after controlling for age, the rate ratio for girls with respect to boys was 0.76 (95% CI: 0.70-0.83). Incidence rate per 100,000 person-years increased from 35.78 in 1989-91 to 50.99 in 2007-2009. Controlling for age and sex, the annual increase was 2.12% (95% CI: 1.45-2.80; test for linear trend:  $p < 0.001$ ). Differences in time trends emerged between genders: among boys, annual percent changes were 4.4% ( $p < 0.001$ ), 2.4% ( $p = 0.034$ ), 0.8% ( $p = 0.423$ ), 1.1% ( $p = 0.214$ ) and 1.2% ( $p = 0.180$ ) in the age groups 0-2, 3-5, 6-8, 9-11, 12-14, respectively; among girls, the same figures were: 4.2% ( $p = 0.006$ ), 3.0% ( $p = 0.013$ ), 4.3% ( $p < 0.001$ ), 1.5% ( $p = 0.127$ ) and 1.2% ( $p = 0.314$ ). Results indicate that whereas for boys the increasing incidence time trend is limited to the youngest age group, it regards girls up to 8 years old. Age-period-cohort models were fitted separately to boys and girls. The best fitting model for boys included age and a linear time trend (drift), meaning that the variation over time had a linear component that could not be ascribed to either the calendar period or the birth cohort. The best fitting model for girls included age and both linear and non-linear effects of calendar period and birth cohort. The figure below shows, in both genders, age effects (expressed as incidence rates vs. age in the reference cohort (1992-97)) and cohort effects (relative risk with respect to the 1992-97 cohort); period effects were constrained to be 0 on average with 0 slope (rightmost and shorter curve).

**Conclusion:** Sardinia has very high and strongly increasing incidence time trends of childhood Type I diabetes. Incidence appears bimodal with age, with a first peak at approximately 3-4 years of age and a second stronger peak at 10-11 years of age. Incidence patterns differ between genders, with strongly non-linear increases among girls.

## 325

## Short chain fatty acids and neutrophils in the pathogenesis of type 1 diabetes

M.H. Harsunen<sup>1</sup>, S. Hummel<sup>1,2</sup>, A. Beyerlein<sup>1</sup>, G. Joslowski<sup>3</sup>, A. von Meyer<sup>4</sup>, M. Pflüger<sup>1,2</sup>, A.-G. Ziegler<sup>1,2</sup>;

<sup>1</sup>Helmholtz Zentrum München, Klinikum rechts der Isar, Technische

Universität München, Neuherberg, <sup>2</sup>Forscherguppe Diabetes e.V.,

Neuherberg, <sup>3</sup>Research Institute of Child Nutrition, Dortmund, <sup>4</sup>Institute of

Clinical Chemistry, Munich Municipal Hospital, Germany.

**Background and aims:** The short chain fatty acids acetate, propionate and butyrate are produced by bacterial fermentation of soluble dietary fiber (SDF) in the intestine and have functional immunomodulatory characteristics. They affect the production of proinflammatory mediators and chemotaxis through the GPR43 receptors, expressed on neutrophils. Recent studies suggest that early dietary factors and the microbial flora influence the development of islet autoimmunity and type 1 diabetes (T1D). We investigated the association between content of soluble fiber in the diet and occurrence of islet autoimmunity/T1D and whether individuals with T1D have altered neutrophil counts.

**Materials and methods:** The SDF intake was analysed using 448 3-day dietary records (after termination of breastfeeding) collected every 3 months from 134 children of the BABYDIET study, a dietary primary intervention study. During follow-up, 26 children developed islet autoantibodies and 7 T1D. We adjusted the content of SDF for total energy intake by calculating residuals from a linear model. The energy-adjusted SDF intake was compared in a case-control analysis between children with and without subsequent development of islet autoimmunity and T1D. Progression to autoimmunity and disease according to the energy-adjusted SDF intake was examined in a multivariable Cox regression model adjusted for age, gender, intervention group and family history of T1D. Neutrophil counts were analysed using hematological data from 107 individuals with new onset of T1D and 12 with islet autoimmunity, collected from participants of prospective diabetes studies, and 1196 age-matched anonymous controls, all individuals without laboratory signs of acute infection.

**Results:** The absolute neutrophil counts were significantly decreased in both T1D cases and individuals with islet autoimmunity compared with controls (median 3.11/nl and 2.33/nl vs 4.11/nl,  $p < 0.0001$ ). After adjustment for age and gender, the differences remained significant. The content of soluble fiber in the diet differed neither in the first year of life (1<sup>st</sup> measurement) nor in the second year of life (2<sup>nd</sup> measurement) between children who subsequently developed islet autoimmunity or T1D and respective controls (mean [SD] residuals 1<sup>st</sup> measurement: no seroconversion 0.16 [1.03], seroconversion -0.09 [1.10],  $p = 0.44$ ; mean [SD] residuals 2<sup>nd</sup> measurement: no seroconversion 0.48 [1.28], seroconversion -0.08 [1.64],  $p = 0.19$ ). Cox regression analyses revealed no significant association between soluble fiber intake and progression to seroconversion/T1D (HR of 1<sup>st</sup> measurement: 0.68 (95% CI: 0.24 - 1.97),  $p = 0.48$ ; HR of difference 1<sup>st</sup> vs 2<sup>nd</sup> measurement: 0.53 (0.17, 1.61),  $p = 0.26$ ).

**Conclusion:** We found no evidence of a reduced soluble fiber intake in the diet as a potential cause of disturbed immune regulation. However, our results suggest for the first time that dysfunction of neutrophils might be involved in the pathogenesis of T1D.

## Maternal fatty acid composition of diet during lactation and risk of preclinical and clinical type 1 diabetes

S. Niinistö<sup>1</sup>, H.-M. Takkinen<sup>2</sup>, L. Uusitalo<sup>1</sup>, J. Nevalainen<sup>3</sup>, M. Kenward<sup>4</sup>, M. Lumia<sup>1</sup>, O. Simell<sup>3</sup>, R. Veijola<sup>5</sup>, J. Ilonen<sup>3</sup>, M. Knip<sup>6</sup>, S.M. Virtanen<sup>1</sup>;

<sup>1</sup>Lifestyle and Participation, National Institute for Health and Welfare,

Helsinki, Finland, <sup>2</sup>University of Tampere, Finland, <sup>3</sup>University of Turku,

Finland, <sup>4</sup>London School of Hygiene & Tropical Medicine, UK, <sup>5</sup>University

of Oulu, Finland, <sup>6</sup>University of Helsinki and Helsinki University Central

Hospital, Finland.

**Background and aims:** We examined maternal dietary fatty acid intake during lactation and whether maternal intake is associated with the risk of pre-clinical and clinical type 1 diabetes in the offspring.

**Materials and methods:** The subjects comprised a cohort of 2939 mother-child pairs from the prospective Type 1 Diabetes Prediction and Prevention (DIPP) study. Composition of maternal diet during the 3rd month of lactation was assessed by a validated food frequency questionnaire. Among the

children with HLA-conferred susceptibility to type 1 diabetes, 143 developed preclinical type 1 diabetes (repeated positivity for islet cell autoantibodies in combination with one or more of the autoantibodies against insulin, glutamic acid decarboxylase or IA-2 protein), and 64 progressed to clinical diabetes. Average follow-up time was 4.1 years [range 0.5–9.7 years]. Piecewise linear log-hazard survival model and Cox proportional hazards regression were used for statistical analyses.

**Results:** Maternal intake of fatty acids during lactation was not associated with the risk of type 1 diabetes in the offspring. Maternal use of oils during lactation was associated with increased risk of preclinical type 1 diabetes (HR 1.22 [95% CI 1.04–1.44]). Low consumption of fresh milk during lactation was associated with higher risk for preclinical type 1 diabetes but only during the first 3 years of life (lowest quarter vs. intermediate half HR 2.04 [95% CI 1.16–3.58]).

**Conclusion:** The observed weak associations suggest that maternal consumption of oils and fresh milk during lactation might have some influence on the development of preclinical type 1 diabetes in the offspring with HLA-conferred susceptibility to type 1 diabetes.

### Effect of high fat diet on serum endotoxin accumulation

M.I.S. Lassenius<sup>1</sup>, V.-P. Mäkinen<sup>1</sup>, M. Jauhiainen<sup>2</sup>, D. Gordin<sup>1</sup>, P. Pussinen<sup>3</sup>, M.-R. Taskinen<sup>4</sup>, J. Kirveskari<sup>5</sup>, C. Forsblom<sup>1</sup>, P.-H. Groop<sup>1</sup>, M. Lehto<sup>1</sup>, FinnDiane Study group;

<sup>1</sup>Folkhälsan Research Inst, Helsinki, <sup>2</sup>National Inst of Health and Welfare, Helsinki, <sup>3</sup>Inst of Dentistry, Univ of Helsinki, <sup>4</sup>Dep of Medicine, Divi of Cardiology, HUCH, <sup>5</sup>Dep of Bacteriology, HUSLAB, Helsinki, Finland.

**Background and aims:** We have recently shown that high levels of endotoxins/lipopolysaccharides (LPS) are associated with features of the metabolic syndrome and the development of kidney disease in patients with type 1 diabetes (T1D). In mammals, an energy rich diet promotes the translocation of gut-derived endotoxins together with chylomicrons to the circulation. Our aim is to investigate whether consecutive high fat meals in healthy controls and T1D patients without nephropathy lead to LPS accumulation.

**Materials and methods:** Participants (controls n=39; T1D n=37) were given three consecutive high fat meals at 8.00, 12.00, and 16.00 (total of 2600kcal). Blood was drawn at fasting and every two hours. Serum LPS activity was measured with the LAL assay (Hycult Biotech). Lipid parameters were determined by standard laboratory assays (HUSLAB, Helsinki) and NMR spectroscopy (NMR metabolomics Laboratory, Kuopio).

**Results:** Consecutive high fat meals had only a modest effect on LPS accumulation. Controls had a higher LPS incremental area (iA) of the initial meal response (8.00–12.00) compared to T1D patients [median 25th–75th quartile: 0.19 (–.31–0.98) vs. –.30 (–.81–0.32); p 0.025]. Fasting LPS and LPS area under curve (AUC) were similar in controls and T1D patients. In the total population, LPS-AUC correlated with triglyceride-AUC (r 0.244; p 0.034), cholesterol-AUC (r 0.245; p 0.033), and LDL-cholesterol-AUC (r 0.283; p 0.013). The strongest correlation was between LPS-AUC and insulin dose (r 0.528; p 0.001). ApoB-48, a specific chylomicron remnant marker, was elevated both at fasting [5.0 (3.7–8.8) vs. 3.6 (2.4–5.4 mmol/l); p 0.004] and AUC [109 (73–166) vs. 82 (49–111); p 0.008] in T1D patients compared to controls. In response to the first meal (8.00–12.00) iA\_ApoB-48 correlated positively with iA\_LPS in T1D patients (r 0.351; p 0.036). HDL cholesterol levels were similar in controls and T1D patients. NMR analysis of serum revealed that T1D patients had more large HDL particles than controls [AUC mean±SD: 4.7\*10<sup>-6</sup>±1.85\*10<sup>-6</sup> vs. 3.58\*10<sup>-6</sup>±1.82\*10<sup>-6</sup>; p 0.011]. This was supported by higher activity of factors involved in HDL-remodeling in T1D patients compared to controls: PLTP [AUC: 67910 (58431–75158) vs. 50903 (46274–75158); p<0.001] and CETP [AUC: 280 (233–313) vs. 248 (210–277); p 0.004]. Paraonase (PON1), an antioxidative enzyme bound to HDL, was lower in T1D patients than in controls [AUC: 191 (135–470) vs. 445 (167–655); p 0.021].

**Conclusion:** In this study we show that consecutive high fat meals do not lead to significant LPS accumulation. Chylomicron metabolism differed between T1D patients and controls, implying possible future vascular problems since ApoB-48 is a risk factor for cardiovascular disease. However, no obvious association between ApoB-48 and LPS was observed. Interestingly T1D patients had a higher proportion of large HDL particles and higher PLTP activity, indicating a potentially accelerated LPS clearance. PON1 activity on the contrary was decreased in T1D vs. controls, again suggesting differences in HDL subpopulations and their composition. To conclude metabolic en-

dotoxemia may be more central in patients with complications such as the metabolic syndrome or diabetic kidney disease.

### Does intrauterine exposure to maternal diabetes accelerate onset of type 1 diabetes in offspring? Results from the T1DGC

A.M. Wägner<sup>1,2</sup>, A. Santana<sup>3</sup>, J.C. Wiebe<sup>1</sup>, M. Hernández<sup>4</sup>, F.J. Nóvoa<sup>1,5</sup>, D. Mauricio<sup>4,6</sup>, T1DGC;

<sup>1</sup>Endocrinology, Complejo Hospitalario Universitario Insular Materno-Infantil, Las Palmas de Gran Canaria, <sup>2</sup>Departamento de Ciencias Médicas y Quirúrgicas, Universidad de Las Palmas de Gran Canaria (ULPGC),

<sup>3</sup>Departamento de Matemáticas y Estadística, ULPGC, Las Palmas de Gran Canaria, <sup>4</sup>Endocrinology, Hospital Arnau de Vilanova, Lleida, Spain,

<sup>5</sup>Ciencias Médicas y Quirúrgicas, Universidad de Las Palmas de Gran Canaria, <sup>6</sup>Institut de Recerca Biomedica, Lleida, Spain.

**Background and aims:** The T1DGC included families with at least 2 siblings with T1D. We previously showed that male gender, risk HLA and negative antibodies were associated with early onset of the disease. The aim of this study was to assess the role of maternal factors on the age of T1D onset in their offspring in the T1DGC dataset.

**Materials and methods:** Two approaches were made for data analysis: multivariate analysis for the search of predictors in the whole dataset and subgroup analysis of children whose mother had diabetes. Early onset of the disease was defined as onset in the lowest tertile (<6 years), whereas childhood-onset diabetes was defined as that diagnosed before the age of 15. Statistical analysis was performed using “R”. To assess the predictors of early and childhood onset, a multivariate regression analysis was performed, including gender, time since diagnosis, antibody positivity, presence of other autoimmune diseases and number of risk and protective HLA haplotypes, maternal age, and (first) birth order as independent variables. High-risk and protective haplotypes were defined according to a previous report from the T1DGC. Mothers with diabetes were identified and classified, both according to type of diabetes and to whether they were diagnosed before or after the birth of their first affected child. Age of onset of the first child with diabetes was compared in the different groups using Wilcoxon-Mann-Whitney’s test.

**Results:** Data including unequivocal HLA haplotypes was available from 2663 families. Median (range) age of onset of the disease was 9(0–49) years. In multivariate analysis, maternal age (p<1.25\*10<sup>-13</sup>) was a significant predictor of both early and childhood onset of the disease, whereas first birth order (p<0.013) was negatively associated. The previously described markers were also confirmed (data not shown). A total of 3228 mothers were identified. Their distribution into the different groups, maternal age at the time of birth of the first affected child and his/her age of onset are shown in the table.

	No diabetes	T1D-before	T1D-after	T2D-before	T2D-after
N	2995	53	31	21	128
Maternal age	26.3(4.7)	26.4(4.1)	23.1(3.5)	29.9(6.1)	26.1(4.7)
Age of onset of T1D	11.0(7.7)	7.8(5.8)*	12.4(8.8)	8.4(5.7)**	13.9(9.6)#

\*p<0.02 compared with no diabetes and T1D-after

\*\*p<0.02 compared with T2D-after

#p<0.002 compared with no diabetes

**Conclusion:** Both increasing maternal age and advanced birth order (after first) are associated with an earlier onset of T1D. Intrauterine exposure to hyperglycaemia also seems to be associated with earlier onset of the disease in offspring, although further analyses are needed to adjust for its interaction with maternal age.

**Diabetes and influenza-attributable health care utilisation: a population-based cohort study**D. Lau<sup>1</sup>, D.T. Eurich<sup>1</sup>, S.R. Majumdar<sup>2</sup>, A. Katz<sup>3</sup>, J.A. Johnson<sup>1</sup>;<sup>1</sup>Department of Public Health Sciences, University of Alberta, Edmonton,<sup>2</sup>Department of Medicine, University of Alberta, Edmonton, <sup>3</sup>Department of Family Medicine, University of Manitoba, Winnipeg, Canada.

**Background and aims:** Guidelines recommend routine vaccination against seasonal influenza in all patients with diabetes. Since vaccinations are already recommended in the elderly, these guidelines single out non-elderly adults with diabetes. However, there is limited evidence that this group actually suffers from increased influenza-related morbidity and mortality compared with otherwise healthy, non-elderly adults. We therefore compared population-based rates of influenza-attributable illness in adults with and without diabetes.

**Materials and methods:** We performed a cohort study using administrative claims data from Manitoba, Canada, between 2000 to 2008. These data capture all drugs and services provided by universal health care. All adults (18 years and older) with diabetes were identified and matched with up to two non-diabetic controls. Our outcomes were physician visits and hospitalizations for influenza-like illness (ILI); and hospitalizations for pneumonia and influenza (PI), and all causes (ALL). Using multivariate Poisson regression to adjust for prior health status, comorbidities, vaccinations, and seasonal trends, we estimated differences in the influenza-attributable rates of each outcome for patients with and without diabetes during periods of known circulating influenza. We performed analyses for all adults, and then separately for the non-elderly (< 65 years) and elderly (>= 65 years).

**Results:** We included 1.17 million person-years of follow-up among 239012 subjects. Of 82027 subjects with diabetes, 51154 (62%) were non-elderly. During the study period, there were 412043 physician visits or hospitalizations for ILI, 7338 PI hospitalizations, and 134799 all-cause hospitalizations. In those with diabetes, circulating influenza increased event rates by (%-relative increase [95% CI]): 14% [12–15%] (ILI), 20% [11–30%] (PI), and 6% [4–8%] (ALL). For those without diabetes, influenza increased event rates by 13% [12–14%] (ILI), 8% [–1–19%] (PI), and 7% [4–9%] (ALL). Formal tests of interaction confirmed a difference in the effect of influenza between those with and without diabetes only for PI hospitalizations (IRR = 1.11 [1.00, 1.22],  $p=0.04$ ). In our age-stratified analyses, we only detected increased rates of influenza-attributable ILI among the elderly (IRR = 1.03 [1.01, 1.05],  $p=0.01$ ) and all-cause hospitalization among the non-elderly (IRR = 1.06 [1.00, 1.11],  $p=0.04$ ). Thus, non-elderly adults with diabetes were significantly more likely than similar adults without diabetes to have influenza-attributable all-cause hospitalizations. This translated into an 54, potentially preventable hospitalizations (approximately 1 per 1000 adults) each year.

**Conclusion:** In non-elderly adults with diabetes, influenza is associated with a relative increase in hospital admissions, for any cause, during influenza season. Nevertheless, the absolute increase in risk is small, and the rationale for targeting vaccinations for non-elderly adults with diabetes depends primarily on the balance of costs and effectiveness of vaccine.

**Enterovirus infection in Tunisian patients with type 1 diabetes mellitus**I. Slim<sup>1</sup>, I. Bousaid<sup>2</sup>, R. Zemni<sup>2</sup>, L. Gueddah<sup>2</sup>, K. Ach<sup>1</sup>, M. Kacem<sup>1</sup>, A. Maaroufi<sup>1</sup>, M. Chaieb<sup>1</sup>, L. Chaieb<sup>1</sup>, F. Ben Hadj Slama<sup>2</sup>;<sup>1</sup>Department of Endocrinology and Diabetology, Farhat Hached University Hospital, <sup>2</sup>Department of Immunogenetics, Ibn Jazzar Faculty of Medicine, Soussa, Tunisia.

**Background and aims:** Type 1 diabetes mellitus (T1DM) is a metabolic disease with serious degenerative complications. The disease is due to progressive autoimmune beta pancreatic islet cells destruction. Environmental factors, especially viruses, are believed to contribute to the pathogenesis of T1DM. Enteroviral (EV) infections have long been suspected in having a role in  $\beta$  cell damaging process and therefore leading to the onset of clinical T1DM. This study was designed to assess a possible link between EV infection and T1DM.

**Materials and methods:** Plasma samples were collected from 95 patients with T1DM (36 children and 59 adults) at age ranging from 5 to 40 years. They were classified according to the course of the disease into two groups: the children (5 children newly diagnosed with T1DM and 31 children with an

older disease) and the adult group which included 16 patients who were at the onset of the disease and 43 patients previously diagnosed with T1DM. Viral RNA was assessed using a highly sensitive nested RT-PCR of the 5' untranslated region (5'UTR) of the genome of EV. Enteroviral infection investigation included as well as control group ( $n = 141$ ) who were clinically free of diabetes or any autoimmune diseases.

**Results:** EV-RNA was detected more frequently in plasma from diabetic patients than in plasma of controls (31,6% vs. 7,8%,  $p < 0,0001$ ; OR = 5,45, IC95% 2,44–12,43). The EV infection was found with a higher frequency in children than in adults. The frequency of positive signals corresponding to enteroviral sequence amplifications were higher in newly diagnosed T1DM children (3/5, 60%) than in their corresponding control children (7/55, 12,7%,  $p = 0,028$ ; OR = 10,29, IC95% 1,10–112,33). We also showed that the frequencies of viral RNA reached the limit of significance in adults recently diagnosed ( $p = 0,075$ ; OR = 4,73, IC95% 0,73–29,60). The statistical analysis of the nested RT-PCR data demonstrates that there was no significant difference in the prevalence of EV infection between newly diagnosed T1DM and previously diagnosed T1DM patients in children and adult groups (3/5, 60%; 18/31, 58,1%,  $p = 1,00$ ; 3/16, 18,8%, 6/43, 14%,  $p = 0.69$ , respectively) although there was a tendency to a decrease of the frequency of EV infection in T1DM older than ten years. GAD and IA-2 antibodies were not significantly associated to EV infection ( $p = 1,00$ ).

**Conclusion:** The present study demonstrates that EV RNA sequences are detected in the plasma from patients at the onset or in the course of T1DM more often than in non diabetic subjects and suggests that EV infection could be involved in the pathogenesis of the T1DM.

## 331

**Autophagy in Coxsackievirus infected pancreatic beta cells**E. Töpfer<sup>1</sup>, K.-P. Knoch<sup>1</sup>, A. Petzold<sup>1</sup>, C. Wegbrod<sup>1</sup>, A. Sönmez<sup>1</sup>, M. Roivainen<sup>2</sup>, M. Solimena<sup>1</sup>;<sup>1</sup>Molecular Diabetology, University of Technology Dresden, Germany,<sup>2</sup>National Institute for Health and Welfare, Helsinki, Finland.

**Background and aims:** Both genetic disposition and environmental factors contribute to the pathogenesis of Type 1 diabetes (T1D). Human Enteroviruses (HEV), including Coxsackieviruses B (CVB), in particular, have been linked to an increased incidence of T1D. Several studies have shown a connection between enterovirus infection and autophagy. The latter process is key for maintenance of cell homeostasis through the degradation and recycling of intracellular organelles and for surveillance of viral infection. Some viruses, however, can arrest autophagosome development and even manipulate autophagy to enable their own lifecycle. Hence, we investigated the involvement of autophagy in the replication of CVB5 in mouse insulinoma MIN6 cells.

**Materials and methods:** MIN6 cells stably transfected with the autophagy marker GFP-LC3 were infected with a mouse cell adapted (MCA) CVB5 DS-1. Four days after infection induction of autophagy and virus replication were analyzed by western blotting for GFP-LC3 and the capsid viral protein (VP1), while GFP-LC3+ compartments (LC3-AC) were isolated from both infected or starved cells and further evaluated for their content.

**Results:** CVB5 infected MIN6 cells expressed higher levels of GFP-LC3B-II and VP1 and both proteins were detected in isolated LC3-AC. LC3-AC isolated from CVB5 infected MIN6 cells contained lower amounts of the ER-marker calnexin compared to not infected cells cultured either in normal conditions or starved. Conversely, LC3-AC from CVB5 infected cells contained higher levels of the membrane granule marker ICA512-TMF, whereas its precursor pro-ICA512 was more abundant in LC3-AC isolated from not infected control or starved cells.

**Conclusion:** The positive correlation between GFP-LC3B-II and VP1 expression suggests that autophagy is implicated in the replication of CVB5. This hypothesis is corroborated by the enrichment of VP1 in LC3-AC. Enrichment of pro-ICA512 in LC3-AC from control or starved cells, and of ICA512-TMF in LC3-AC from CVB5 infected cells further suggest that autophagosomes of control or starved cells use mainly the ER as a membrane source, whereas those of CVB5 infected cells utilize secretory granule membranes.

## PS 008 Monogenic forms of diabetes

### 332

#### Integration of biomarkers and clinical characteristics provides the best method for identifying patients with MODY

B.M. Shields<sup>1</sup>, T.J. McDonald<sup>2</sup>, K.R. Owen<sup>3</sup>, M.T. Malecki<sup>4</sup>, R.E.J. Besser<sup>1</sup>, A.G. Jones<sup>1</sup>, S. Ellard<sup>2</sup>, A.T. Hattersley<sup>1</sup>;

<sup>1</sup>Peninsula Medical School, University of Exeter, UK, <sup>2</sup>Royal Devon and Exeter NHS Foundation Trust, Exeter, UK, <sup>3</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, UK, <sup>4</sup>Department of Metabolic Diseases, Jagiellonian University Medical College, Krakow, Poland.

**Background and aims:** Maturity-onset diabetes of the young (MODY) is a rare, young-onset form of diabetes, often misdiagnosed as Type 1 diabetes (T1D) or Type 2 diabetes (T2D), resulting in inappropriate management. A number of biomarkers have been proposed to aid identification of patients with MODY and clinical characteristics (age at diagnosis, BMI, HbA<sub>1c</sub>, parent with diabetes, treatment) are useful when combined in a clinical prediction model. We aimed to determine if combinations of biomarkers and clinical criteria improves the diagnostic accuracy for detecting MODY in patients diagnosed under 45.

**Materials and methods:** We measured plasma C-peptide and GAD and IA-2 antibodies on patients insulin treated within 6 months of diagnosis (144 T1D, 71 MODY), and hsCRP and HDL cholesterol in patients not insulin treated within 6 months of diagnosis (118 T2D, 216 MODY). Probability of MODY for each patient was derived using the clinical prediction model. Discriminative ability of the biomarkers/criteria was assessed using Receiver Operating Characteristic (ROC) curves.

**Results:** In patients insulin treated within 6 months of diagnosis, C-peptide > 80 pmol/L and absence of GAD/IA-2 antibodies had 90% sensitivity, 93% specificity for MODY. The addition of clinical characteristics provided a minor improvement in diagnostic accuracy (ROC AUC 0.95 v 0.99,  $p < 0.001$ ; perfect test AUC = 1). In patients not insulin treated within 6 months of diagnosis, hsCRP < 0.75 mg/L and HDL > 1.12 mmol/L had 56% sensitivity and 87% specificity. The addition of clinical characteristics greatly improved diagnostic accuracy (ROC AUC 0.81 v 0.98,  $p < 0.0001$ ).

**Conclusion:** The use of multiple biomarkers outperforms single biomarkers for predicting MODY. Excellent discrimination between MODY and Type 1/Type 2 diabetes is achieved when biomarkers are used in combination with clinical characteristics.

#### Assessment of new clinical criteria to search for HNF1A MODY in patients with initial diagnosis of type 1 or type 2 diabetes mellitus

M. Szopa, M. Grzanka, B. Kiec-Wilk, N. Nowak, B. Matejko, M.T. Malecki, T. Klupa;  
Metabolic Diseases, Jagiellonian University Medical College, Krakow, Poland.

**Background and aims:** The most common form of maturity-onset diabetes of the young (MODY) is caused by mutations in the hepatocyte nuclear factor 1A (HNF1A) gene. It has been established that patients with HNF1A MODY are very sensitive to sulphonylureas (SU) and can also discontinue insulin treatment. However, most of patients with this monogenic diabetes are misdiagnosed as having type 1 (T1DM) or type 2 (T2DM) diabetes mellitus and hence receive non-optimal treatment.

**Materials and methods:** The aim of our study was to test new clinical criteria for selecting patients for HNF1A MODY molecular testing: a) for patients initially diagnosed as T2DM, the selection criteria were as follows - effective SU based oral treatment for more than 15 years and body mass index < 30 kg/m<sup>2</sup>; b) for patients with T1DM clinical diagnosis, we selected individuals currently treated with continuous subcutaneous insulin infusion (CSII) - for those individuals it is possible to obtain very precise and dependable information concerning insulin dosing based on insulin pump downloads. Selection criteria included total daily insulin requirement (TDIR) of less 0.3 IU/Kg at least five years after diabetes diagnosis and basal insulin requirement of less than 30% of TDIR.

**Results:** We analyzed medical records of 664 diabetic patients, 524 clinically diagnosed as T2DM and 159 classified as T1DM. Based on examined clinical

criteria, we selected 14 subjects from patients with T2DM clinical diagnosis; eventually 11 of them were available for the HNF1A gene sequencing. In one patient from this group, we have found a large deletion including nucleotides 1380-1408, which is a causative variant of diabetes in this subject (9% of sequenced cases). Among patients with T1DM clinical diagnosis who were treated with CSII and who met selection criteria, the previously described diabetes-related mutation in exon 4 (P291fsinsC) was found in one individual (50% of analyzed cases).

**Conclusion:** In conclusion, we present new clinical criteria which may be helpful in pre-selecting patients for molecular testing in search for the HNF1A MODY.

#### The incretin effect in patients with maturity onset diabetes of the young

S.H. Østoft<sup>1,2</sup>, J.I. Bagger<sup>1,2</sup>, T. Hansen<sup>3</sup>, O. Pedersen<sup>3</sup>, J.J. Holst<sup>2,3</sup>, F. Knop<sup>1</sup>, T. Vilsbøll<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, Diabetes Research Division, Hellerup,

<sup>2</sup>Department of Biomedical Sciences, Panum Institute, Copenhagen, <sup>3</sup>Novo Nordisk foundation Center for Basic Metabolic Research, Copenhagen, Denmark.

**Background and aims:** Maturity onset diabetes of the young (MODY) is a clinically and genetically heterogeneous subgroup of non-autoimmune diabetes, constituting about 1-2% of all diabetes. The incretin effect (the enhancement of glucose-induced insulin secretion following oral glucose tolerance test (OGTT) compared to isoglycaemic intravenous glucose infusion (IIGI)) is unclear in MODY patients. In the present study we studied the incretin effect in patients with MODY2 (glucokinase gene mutations) and MODY3 (hepatocyte nuclear factor 1a gene mutations) and in a group of matched control subjects.

**Material and methods:** Ten MODY3 patients (age: 31±3 years (mean±SEM); body mass index (BMI): 24±1 kg/m<sup>2</sup>; fasting plasma glucose (FPG): 8.4±0.8 mmol/L; HbA<sub>1c</sub>: 7.0±0.3%), 9 MODY2 patients (age: 43±5 years; BMI: 24±2 kg/m<sup>2</sup>; FPG: 7.3±0.3 mmol/L; HbA<sub>1c</sub>: 6.7±0.2%) and 9 control subjects (age: 41±5 years; BMI: 24±1 kg/m<sup>2</sup>; FPG: 5.1±0.2 mmol/L; HbA<sub>1c</sub>: 5.3±0.1%) were examined on 2 separate occasions: 4h 50 g-OGTT and IIGI.

**Results:** MODY3 patients exhibited more severe glucose intolerance (evaluated from area under curve during OGTT) than MODY2 patients (3,041±302 mmol/L×4h vs. 2,139±59 mmol/L×4h,  $p=0.0126$ ) compared to the control subjects (1,351±20 mmol/L×4h;  $p<0.001$  and  $p<0.001$ , respectively). Isoglycaemia was obtained using 37±4 g and 30±3 g of glucose during IIGIs in patients with MODY3 and MODY2, respectively ( $p=NS$ ), and 24±2 g in control subjects ( $p=0.01$  and  $p=0.11$ , respectively). The incretin effect [ $100\% \times (AUC_{C-peptide, OGTT} - AUC_{C-peptide, IIGI}) / AUC_{C-peptide, OGTT}$ ] amounted to 17±5% and 26±3% in patients with MODY3 and MODY2, respectively ( $p=NS$ ) and 36±4% in the control subjects ( $p=0.018$  and  $p=NS$ , respectively).

**Conclusion:** Our data suggest that MODY2 patients are the first group of diabetes patients ever seen with normal incretin effect. In contrast, MODY3 patients were characterized by an impaired incretin effect when compared to control subjects. The differences are most likely explained by differences in the etiology and glucose tolerance between MODY3 and MODY2 patients.

#### Whole exome sequencing identifies CUL9 as a MODY-X gene

N. Iwasaki<sup>1,2</sup>, A. Saito<sup>3</sup>, T. Furukawa<sup>2</sup>, M. Takizawa<sup>1</sup>, R. Fujimaki<sup>1</sup>, M. Ogata<sup>1</sup>, Y. Uchigata<sup>1</sup>;

<sup>1</sup>Diabetes Center, Tokyo Women's Medical University, <sup>2</sup>Institution of Integrated Medical Science, Tokyo Women's Medical University, <sup>3</sup>STAGEN, Tokyo, Japan.

**Background and aims:** Whole exome sequencing is known to be a powerful tool for identifying the causative mutations in Mendelian diseases. We have previously determined the regions of Max NPL > 3.0 on chromosomes 6, 7 and 22 by linkage analysis, in one Japanese MODY family that showed > 60% power to detect NPL score > 2.0. However, regions detected were still too broad to screen. The aim of this study is to identify the causative variants of MODY-X by combining the information with whole exome sequencing on the linkage data.

**Materials and methods:** The MODY-X family with three generations consisted of 31 members was studied. Genomic DNA was available from 31 subjects. Affection status was confirmed by 75g OGTT, if the individual was not screened for diabetes mellitus. We performed whole exome sequencing for four individuals including the proband, the daughter and the nephew with MODY and the spouse of the proband who was not affected. Exomes (38 Mb of genomic sequence) of four individuals using the SureSelect human exome kit (Agilent) were subsequently sequenced using a SOLiD sequencing slide (Life Technologies). Bioscope was used for detecting SNPs and insertion-deletions. Polyphen and SIFT were used for selecting the variants. The causative genes were defined as to satisfy all four criteria; 1) located in the protein coding region, 2) heterozygous only in patients, 3) unknown SNP (not deposited in dbSNP nor in 1000 Genome), and 4) matched with linkage results.

**Results:** On average, 50% of exome in the proband and 85% of exome in the remaining individuals were covered more than tenfold, and 156,959 genetic variants were identified including 20,162 non-synonymous changes. The number of the variants fulfilled the criteria of 1), 2), 3) and also located on chromosomes 6, 7 and 22 were 41. The screening by Polyphen score > 0.6 and/or SIFT score 2.0 selected CUL9 and HMGCL1 those located on the peak on chromosome 6. However, HMGCL1 was rejected by Sanger sequence, and only CUL9 satisfied both Polyphen and SIFT scores.

**Conclusion:** We identified CUL9 as the MODY-X gene based on the linkage results in combination with a massively parallel sequencing of whole exome, though the functional properties needs to be elucidated.

#### Identification of a new mutation of C1SD2 gene in siblings with Wolfram syndrome 2

M. Rondinelli<sup>1</sup>, F. Novara<sup>2</sup>, V. Calcaterra<sup>2</sup>, L. Bucciarelli<sup>1</sup>, V. Valdes<sup>1</sup>, D. Larizza<sup>2</sup>, O. Zuffardi<sup>2</sup>, S. Genovese<sup>1</sup>

<sup>1</sup>IRCCS Multimedica, Sesto San Giovanni, Italy, <sup>2</sup>IRCCS San Matteo University of Pavia, Italy.

**Background and aims:** Wolfram syndrome (WFS; MIM 222300) is an autosomal recessive neurodegenerative disorder. Affected individuals suffer by juvenile-onset insulin-requiring diabetes mellitus. Other neurological and endocrine manifestations include optic atrophy, sensorineural deafness, psychiatric illnesses, diabetes insipidus, renal-tract abnormalities and bladder atony. One gene for the disorder, WFS1, on chromosome 4p16.3, encodes a transmembrane protein, Wolframin, located in the endoplasmic reticulum (ER), which plays a role in calcium homeostasis. A second gene, WFS2 (C1SD2), on chromosome 4q22-24 encodes for ERIS (endoplasmic reticulum intermembrane small protein). An extensive phenotypic analysis showed additional symptoms in individuals with WFS2, such as significant bleeding tendency, as well as a defective platelet aggregation with collagen; a considerable number of patients with WFS2 had also peptic ulcer disease. We performed genetic analysis of an Italian family composed by two sisters affected by WFS and their unaffected parents. The probands suffer by the following abnormalities, reported in chronological order according to diagnosis: peptic ulcer, diabetes mellitus, diabetes insipidus, sensorineural deafness, amenorrhoea, optic atrophy and bladder atony.

**Materials and methods:** EDTA blood was obtained and genomic DNA was isolated by using QIAamp DNA Blood Mini Kit (Qiagen) according to the manufacturer's protocol. The three C1SD2 coding exons were amplified by PCR using Go Taq(R) Flexi DNA Polymerase (Promega). Sequence primers and experimental conditions are available on request.

**Results:** C1SD2 (NM\_001008388) sequencing analysis revealed a novel homozygous substitution (cDNA: NM\_001008388.4:c.103+1G>A, DNA Level: Chr4(GRCh37):g.103790345G>A) in the donor splice site of intron 1 in the probands. Both parents resulted heterozygous for the same mutation.

**Conclusion:** C1SD2 is the second member of the gene family containing the CDGSH iron sulfur domain. There are currently three members in this gene family: C1SD1 (synonyms ZCD1, mitoNEET), C1SD2 (synonyms ZCD2, Noxp70, and Miner1) and C1SD3 (synonym Miner2). C1SD2 gene has been identified as the second causative gene associated with WFS. Moreover, recent studies demonstrated that C1SD2 deficiency causes mitochondrial-mediated phenotypic defects in mice and C1SD2 knockout mice exhibit many clinical manifestations of WFS patients including early-onset degeneration of central (e.g., optic) and peripheral (e.g., sciatic) nerves and premature death, as well as impaired glucose tolerance. The homozygous substitution identified in C1SD2 gene of our patients maps in the donor splice site of in-

tron 1 (c.103+1G>A). This mutation was not found in the single nucleotide polymorphism database (dbSNP; www.ncbi.nih.gov/projects/SNP/). Further study of parents revealed that they carried the mutation in a heterozygous state. Comparative genomics analysis, by aligning nucleotide sequences of different species, such as chimp, rhesus, cat and mouse showed that the site of identified mutation is conserved during evolution. Functional predictions of the homozygous mutation were performed using bioinformatics methods such as Alamut and Mutation Taster (<http://www.mutationtaster.org/>).

### 337

#### Localisation of hepatocyte nuclear factor-4alpha in the nucleolus and nucleus is regulated by its C-terminus

M. Ogata, N. Iwasaki, R. Fujimaki, M. Takizawa, Y. Uchigata;

Tokyo Women's Medical University, Diabetes Center, Tokyo, Japan.

**Background and aims:** Mutations in hepatocyte nuclear factor-4α (HNF4α) lead to various diseases, among which C-terminal deletions of HNF4α are exclusively responsible for maturity onset diabetes of the young 1 (MODY1). MODY is an autosomal dominant disease characterized by a primary defect in insulin response to glucose, suggesting that the C-terminus of HNF4α is important for pancreatic β-cell function. To clarify the role of the C-terminus of HNF4α, changes in cellular localization and the binding ability to its regulator were examined, specifically in the region containing Q268, which deletion causes MODY1.

**Materials and methods:** Cellular localization of mutant HNF4α were examined in monkey kidney 7 (COS7), Chinese hamster ovary(CHO), rat insulinoma (INS-1) and mouse insulinoma (MIN6) cells, and their binding activity to other proteins were examined by fluorescence resonance energy transfer (FRET) in COS7 cells.

**Results:** Although wild-type HNF4α was localized in the nucleoplasm in transfected cultured cells, Q268X-HNF4α was located predominantly in the nucleolus. Deletion analysis of the C-terminus of HNF4α showed that the S337X-HNF4α mutant, and other mutants with shorter amino acid sequences (S337-K194), were mostly localized in the nucleolus. HNF4α mutants with amino acid sequences shorter than the W192X-HNF4α mutant gradually spread to the nucleoplasm in accordance with their lengths. The A250X-HNF4α mutant was capable of causing the accumulation of HNF4α or the small heterodimer partner (SHP), one of the HNF4α regulators, in the nucleolus. However, the R154X-HNF4α mutant did not have binding ability to wild-type HNF4α or SHP, and thus was seen in the nucleus.

**Conclusion:** The C-terminus sites might play a key role in facilitating the nucleolar and subnucleolar localization of HNF4α.

#### Inefficient preproinsulin translocation links to late onset diabetes

M. Liu<sup>1</sup>, H. Guo<sup>1</sup>, Y. Xiong<sup>1</sup>, R. Lara-Lemus<sup>1</sup>, S.-O. Shan<sup>2</sup>, P. Arvan<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, University of Michigan, Ann Arbor,

<sup>2</sup>Division of Chemistry and Chemical Engineering, California Institute of Technology, Pasadena, USA.

**Background and aims:** In pancreatic beta cells, insulin biosynthesis begins as a precursor, preproinsulin (PPI), within the cytosol. To enter the secretory pathway, the signal peptide (SP) of newly synthesized PPI recognized by signal peptide recognition particle (SRP) drives PPI to and across the endoplasmic reticulum (ER) membrane. Recently, two SP mutations, R6C and R6H, close to the amino terminus of PPI were reported to cause late onset diabetes in humans. The mutations decrease SP positive charge, which may affect ER targeting/translocation efficiency of PPI. However, a new study has suggested that the protein encoded by these mutations could still be targeted to insulin secretory granules, raising the question of how these SP mutations could cause diabetes.

**Materials and methods:** We use metabolic labeling to examine co-translational translocation and SP cleavage of wild-type and mutant PPIs.

**Results:** Upon metabolic labeling of newly synthesized PPIs, we found that, although the mutant SPs could be recognized by SRP and targeted to the ER membrane, up to 50% of mutant PPIs failed to fully translocate into the ER lumen, which resulted in a ~50% decrease of insulin production from the mutant PPIs in transfected pancreatic beta cells. Interestingly, this translocation defect was fully rescued by restoring positive charge to the mutant SPs, indicating that positive charge within the SP plays an important role in

efficiency of PPI translocation. All patients carrying these mutations are heterozygous, yet, the insulin haploinsufficiency cannot itself account for diabetes. To examine the molecular mechanisms of beta cell failure associated with these mutants, we co-expressed mutant and wild-type (WT) PPIs. We found that, unlike other mutant (pre)proinsulins associated with the syndrome of Mutant INS-gene-induced Diabetes of Youth (MIDY), these two mutant PPIs did not affect normal trafficking and insulin production of co-expressed WT proinsulin. Instead, the translocation defect led to accumulation of the untranslocated PPIs in the cytosol, which might be toxic to pancreatic beta cells, leading to late onset diabetes.

**Conclusion:** Our study suggests that preproinsulin SP mutations associated with late onset diabetes are mistargeted and accumulated in the cytosol. Manipulating cellular events that accelerate degradation and prevent aggregation of untranslocated PPIs may protect beta cells from the toxicity of these mutants.

## PS 009 Diabetes, cardiovascular disease and mortality

339

### Coronary artery disease as a risk for developing type 2 diabetes mellitus

C.H. Saelly<sup>1,2</sup>, A. Vonbank<sup>3,1</sup>, P. Rein<sup>3,1</sup>, S. Beer<sup>3,1</sup>, H. Drexel<sup>1,4</sup>,

<sup>1</sup>VIVIT Institute, Feldkirch, Austria, <sup>2</sup>Private University of the Principality of Liechtenstein, Triesen, Liechtenstein, <sup>3</sup>Academic Teaching Hospital, Feldkirch, Austria, <sup>4</sup>Drexel University College of Medicine, Philadelphia, USA.

**Background and aims:** Diabetes mellitus is a major risk factor for coronary artery disease (CAD); whether conversely CAD confers an increased risk for diabetes has not been studied so far and is addressed in the present study.

**Materials and methods:** We prospectively recorded incident diabetes over 7.5 years in 506 consecutive non-diabetic Caucasian patients undergoing coronary angiography for the evaluation of stable CAD, covering 3795 patient years.

**Results:** During follow-up, diabetes was newly diagnosed in 107 patients, i.e. in 21.1% of the study population or in 2.8% per year. Patients with significant CAD (n=293) when compared to subjects who did not have significant CAD at the baseline angiography were at a 33% (p = 0.027) increased diabetes risk. However, the relationship between CAD and incident diabetes was attenuated and no longer statistically significant after adjustment for potential confounders including metabolic syndrome (MetS) status. The MetS as diagnosed according to the current consensus definition in turn was strongly predictive of diabetes, in particular when the more selective NCEP-ATP-III waist cut-off values were applied for its diagnosis (OR = 2.91 [1.83–4.64]; p < 0.001).

**Conclusion:** We conclude that albeit apparently not causally related to diabetes incidence, the presence of CAD indicates a strongly increased risk for incident diabetes. Repeated diabetes screening of coronary patients and targeted programs to prevent diabetes in these high-risk patients are warranted.

### Glycaemic status, diabetes, and cardiovascular risk: a new risk score for the aged Southern European population

R. Gabriel<sup>1</sup>, C. Brotons<sup>2</sup>, J. Muñoz<sup>3</sup>, J. Tuomilehto<sup>1</sup>,

<sup>1</sup>Clinical Epidemiology, Hospital Universitario La Paz, Madrid, <sup>2</sup>EAP Sardenya, Barcelona, <sup>3</sup>Universidad de A Coruña, A Coruña, Spain.

**Background:** The impact of diabetes mellitus (DM) on cardiovascular disease (CVD) risk is an important aspect to be considered in risk assessment. The European HEARTSCORE did not consider the impact of glycaemic status, anti-diabetic treatment and the age groups older than 70 years on the total CVD risk.

**Objective:** To develop a new CVD risk prediction tool, including information on glycaemic status, treatment of diabetes, to accurately estimate the individual cardiovascular risk in Southern Europe, where elderly people account for more than 25% of the total population, and have higher prevalence of DM than middle-aged groups.

**Methods and material:** The project assembled a pool of 7 Spanish cohort studies including middle-aged (30–70 years) and elderly individuals (>70 years). There were 11,800 persons free of CVD at baseline (5,413 men and 6,387 women) representing 108,569 person years of follow-up. DM was defined as FPG ≥ 7.0 mmol/L, random capillary FG ≥ 11.1 mmol/L or treatment with any anti-diabetic drug at baseline. Cox regression analyses were conducted to examine the contributions of the different variables to CVD forming the potential basis for the development of the CVD risk-score (ERICE-score).

**Results:** Overall prevalence of DM at baseline was 8.6% (8.8 in males, and 8.4 in females). A total of 1,214 cardiovascular events were identified, of which 633 were fatal. Age was the strongest risk factor for CVD. With regard to modifiable risk factors, in men, high SBP was the strongest predictive factor of CVD followed by DM and smoking with similar impact. In women, DM plays a crucial role followed by smoking and high SBP. Multivariate adjusted hazard ratios for CVD in people with treated DM, compared to non-diabetics, were 1.37 (95%CI:1.22–1.46) in men and 1.59 (1.30–1.69) in women. The contribution of high total-cholesterol levels to the CVD risk was only significant, both in men and women, in younger than 70 years.

**Conclusion:** Separate risk chart are given for treated diabetics, non-treated diabetics and non-diabetics, both for males and females, because the absolute risk increased with its combination, with the highest risk in men treated diabetics. The individual contribution of DM to the global CVD risk was also higher than total-cholesterol in this aged Southern European population.

### Excess mortality in the English National Diabetes Audit is greater in younger people as compared with older people who have both type 1 and type 2 diabetes

B. Young<sup>1</sup>, D. Eayres<sup>2</sup>, A. Uddin<sup>2</sup>, J. Henderson<sup>2</sup>,

<sup>1</sup>Salford Royal Hospital, Salford, <sup>2</sup>HSCIC, Leeds, UK.

**Background and aims:** Data from English National Diabetes Audit (NDA) was investigated to determine whether age, sex and type of diabetes are related to excess mortality in diabetics.

**Materials and methods:** Using unique person identifiers (NHS numbers) from the 1.7 million people with diabetes included in the 2007/8 NDA the UK Office of National Statistics identified 49,282 deaths during the year beginning 1 November 2008. The diabetes cohort's mortality was investigated using age and sex-specific mortality rates, directly age-standardised rates (DSR) and indirectly age-standardised mortality ratios (SMR), with England 2009 as the standard population.

**Results:** The crude death rate for all people with diabetes was 3,553 per 100,000 per year (background England rate 886). People with type 1 diabetes had the highest mortality with a DSR of 2,016 compared to 1,462 for people with type 2 diabetes and 886 for the background England population. The SMRs suggest that, compared with the background mortality rates, there are approximately 2.5 times as many deaths in people with type 1 diabetes and 1.5 times as many in people with type 2 diabetes. In total there were >16 thousand more deaths of people with diabetes than would have occurred if their mortality risk was equal to that of the general population. Extrapolating this to include people with diabetes not in the audit, suggests that in 2008–9 about 21 thousand excess deaths occurred in people with diabetes in England. Compared to the background population both males and females with type 1 diabetes were 2.5 times more likely to die while for type 2 diabetes the corresponding rates were 1.4 for males and 1.5 for females. In all instances this excess mortality was inversely related to age: in the 15–34 age group, females with type 1 diabetes had mortality approximately 9 times the background female rate while in males it was 4 times (largely because the background mortality in young males is much higher than for females); for type 2 diabetes the figures are approximately 6 and 3.6 times respectively; in the 85+ age group all of the ratios drop to less than 2. Compared to the general population there was less excess male mortality in type 1 diabetes: no excess in the 15–34 age group and a gradual increase to 1.3 times in the over 85s; by contrast for type 2 diabetes excess male mortality is constant over all age groups at approximately 1.2 times the female rate.

**Conclusion:** Compared with the general population the contemporary risk of death in people with diabetes is higher at all ages in both sexes and in both Type 1 and Type 2 diabetes but the relative risk is greatest in the young and in females with Type 1 diabetes.

## 342

### Other causes of death - are there any unexpected specific mortality rates in diabetes patients?

S. Ioacara<sup>1</sup>, C. Guja<sup>1</sup>, C. Ionescu-Tirgoviste<sup>1</sup>, S. Fica<sup>2</sup>, S. Martin<sup>2</sup>, S. Sabau<sup>3</sup>, C. Tiut<sup>4</sup>;

<sup>1</sup>"I. Pavel" Outpatient Clinic, Bucharest, Romania, <sup>2</sup>"Elias" Hospital, Bucharest, Romania, <sup>3</sup>"Tokai" University, Sapporo, Japan, <sup>4</sup>"University" Hospital, Bucharest, Romania.

**Background and aims:** Almost all research papers on mortality are focused on all-cause, cardiovascular, cancer, diabetes-related or chronic kidney disease. The remaining causes of death are designated as "other causes" and usually overlooked. This study investigated the mortality from other causes of death in type 2 diabetes (T2DM).

**Materials and methods:** All diabetes subjects residing in a major urban area and its surroundings were included at the moment of their first diabetes pre-

scription between 01/01/2001 and 12/31/2008 (n=82763). Subjects younger than 40 years (n=4940), insulin treated at baseline (n=11936), follow-up <6 months (n=760), and missing essential data (n=2547) were excluded. All 62580 remaining T2DM subjects oral-treated at baseline were followed-up for all-cause / other causes mortality until 12/31/2010, by cross-linking with the National Institute of Statistics mortality database, based on International Classification of Diseases 10th revision (ICD10). Deaths from "other causes" (ICD10 codes: A00-B99, D10-E09, E15-H95, J00-N16, N20-T99) were divided into 5 categories according to medical relevance, and 11 subcategories based on the availability of at least 10 deaths in both men and women. Control group was constructed using the general population data adapted to the yearly age and sex distribution of the diabetes group. Standardised mortality ratios (SMR) were calculated.

**Results:** The mean age at baseline was 62±10.2 years (61±10.3 years in men and 62.9±10 years in women, p<0.001), with a mean follow-up of 6.4±2.8 years (6.3±2.8 years in men and 6.5±2.8 years in women, p<0.001) leading to 402,243.1 person-years of follow-up and 13459 all-cause deaths (1705 deaths from other causes). The control group contributed 98,202,901 person-years and 3,304,629 all-cause deaths (512742 deaths from other causes). SMR for the five major categories of death from "other causes" are presented in table 1.

Table 1

Cause of death (ICD10)	Males SMR (CI95, p)	Females SMR (CI95, p)
Infectious (A00-B99)	0.29 (0.182-0.44, p<0.001)	0.816 (0.499-1.265, p=0.387)
Respiratory (J00-J99)	0.568 (0.5-0.643, p<0.001)	1.087 (0.957-1.229, p=0.192)
Digestive (K00-K93)	1.015 (0.925-1.111, p=0.748)	1.101 (0.988-1.223, p=0.078)
Injury and poisoning (S00-T98)	0.502 (0.425-0.59, p<0.001)	0.79 (0.632-0.977, p=0.034)
Other (D10-E09, E15-H95, L00-N16, N20-R99)	0.544 (0.425-0.687, p<0.001)	0.998 (0.801-1.229, p=0.983)

In females, the top 3 SMR (CI95%, ICD10 codes) for subcategories of death were pulmonary oedema 4.866 (3.815-6.122, p<0.001, J81), chronic lower respiratory 0.411 (0.305-0.542, p<0.001, J40-J47), and paralytic ileus and intestinal obstruction 1.879 (1.282-2.663, p<0.001, K56), while in males chronic lower respiratory 0.245 (0.189-0.313, p<0.001, J40-J47), tuberculosis 0.265 (0.151-0.434, p<0.001, A15-A19), and pulmonary oedema 2.979 (2.206-3.939, p<0.001, J81).

**Conclusion:** There was a significant effect of sex on standardised mortality ratios. With few exceptions, in T2DM patients oral-treated at baseline specific mortality rates generally designated as "other causes" were either similar or lower compared with the age and sex matched general population.

## 343

### HbA<sub>1c</sub> levels and all-cause mortality in type 2 diabetic patients: an epidemiological contribution to the definition of therapeutic targets

I. Dicembrini<sup>1</sup>, M. Monami<sup>2</sup>, V. Vitale<sup>3</sup>, C. Lamanna<sup>3</sup>, N. Bartoli<sup>2</sup>, D. Martelli<sup>2</sup>, S. Zannoni<sup>2</sup>, A. Antenore<sup>2</sup>, G. Toffanello<sup>2</sup>, N. Marchionni<sup>2</sup>, E. Mannucci<sup>2</sup>;

<sup>1</sup>Pathophysiological Department, Section of Endocrinology, Florence, <sup>2</sup>Department of Cardiovascular Medicine, Section of Geriatric Cardiology and Medicine, Florence, <sup>3</sup>Diabetes Agency, Careggi Teaching Hospital, Florence, Italy.

**Background and aims:** Aim of the present case-control study is to explore the effect of case mix on the relationship between HbA<sub>1c</sub> and mortality in type 2 diabetic patients (T2DM).

**Materials and methods:** A nested case-control study dataset was generated from the cohort-study dataset (n=4,140 T2DM outpatients) by sampling controls from the risk sets. Cases (N=427), were compared with an equal number (N=427) of controls chosen from those members of the cohort who were at risk for the same follow-up time of the case, matched for age (± 3 years)-, sex-, BMI (± 2 Kg/m<sup>2</sup>)-, duration of diabetes (± 5 years)-, and Charlson's Comorbidity Score (CCS) (± 1). The main predefined analysis was the comparison of cases and controls for proportion of patients with each HbA<sub>1c</sub> class (<6.5, 6.5-7.4, 7.5-8.4, and ≥8.5%) compared with Chi-square test. Chi-square test was used for between-group comparisons of categorical variables.

**Results:** During a mean follow-up of 5.7±3.5 years, 427 deaths were recorded. The lowest risk of death was observed in the HbA<sub>1c</sub> 6.5-7.4% category. The risk associated with a low (<6.5%) baseline and mean HbA<sub>1c</sub> was signifi-

cantly greater in patients who were insulin-treated at baseline than in the rest of the sample. A moderately elevated mean, but not baseline, HbA1c (7.5–8.4%) was associated with increased risk in non-insulin-treated patients only, whereas higher ( $\geq 8.5\%$ ) HbA1c levels, either at baseline or during follow-up, were associated with increased risk both in insulin-treated and non-insulin-treated individuals (Fig. 1, panel A and B). In a multivariate analysis, adjusting for metformin exposure and renal insufficiency, mean HbA1c during follow-up  $<6.5\%$  was associated with increased mortality in insulin-treated patients (6.22[1.06–39.82],  $p=0.045$ ), but not in non-insulin-treated subjects (1.32[0.58–3.03],  $p=0.51$ ). The increase in risk associated with HbA1c  $<6.5\%$  among insulin-treated patients was similar in those with or without known ischemic heart disease (1.64[0.90–3.80],  $p=0.25$ , and 1.72[0.90–3.29],  $p=0.10$ , respectively).

**Conclusion:** The present study suggests that glycemic targets should be individualized on the basis of the characteristics of each patient, considering age, comorbidity, and duration of diabetes. Caution should be used in prescribing insulin to reach near-normoglycemia, particularly in older, frail patients. Figure 1. Risk ratio for all-cause mortality across baseline (panel A) and mean HbA1c (panel B) categories in different subgroups of patients. Non insulin-treated patients (dark grey), insulin-treated patients (light grey). The scale is logarithmic. \* =  $p<0.01$ ;  $\dagger$  =  $p<0.05$ ;  $\circ$  =  $p<0.10$  vs reference at conditional logistic regression.

**Figure 1**

### 344

#### Total mortality by elevated transferrin saturation and hemochromatosis genotype in individuals with diabetes - risk of premature death

C. Ellervik<sup>1</sup>, H.U. Andersen<sup>2</sup>, A. Tybjaerg-Hansen<sup>1</sup>, M. Frandsen<sup>2</sup>, H. Birgens<sup>1</sup>, B.G. Nordestgaard<sup>1</sup>, T. Mandrup-Poulsen<sup>1</sup>

<sup>1</sup>Faculty of Health Sciences, University of Copenhagen, <sup>2</sup>Steno Diabetes Center, Copenhagen, Denmark.

**Background and aims:** Mortality is increased in patients with clinically overt hereditary hemochromatosis, but also in the general population with increasing transferrin saturation independently of hemochromatosis genotype. Whether increased transferrin saturation (TS) as a proxy for iron overload or hemochromatosis genotype associate with increased mortality in patients with diabetes is unknown.

**Materials and methods:** In a prospective observational study, we examined mortality according to baseline TS or hemochromatosis genotype in patients with type 1 diabetes with onset  $\geq 30$  years of age (median age: 58 years, diabetes-duration (median): 20 years) recruited in 1999 (N=716, cohort I), and mortality according to baseline TS in patients with type 1 (N=2656, age (median): 45 years, diabetes-duration (median): 26 years) or type 2 (N=3176, age (median): 63 years, diabetes-duration (median): 10 years) or other (N=288) diabetes diagnosed at any age and recruited between 2001–2007 (N=6120, cohort II). During 12 years of follow-up, 1553 patients with diabetes died.

**Results:** In cohort I+II (N=6836), the cumulative survival was decreased in patients with TS  $\geq 50\%$  versus  $<50\%$  (log-rank  $P=0.004$ , adjusted hazard ratio (HR) 1.4 (95% confidence interval (CI): 1.1–1.9;  $P=0.005$ ), population attributable risk (PAR) 2%, and median survival 75 years in TS  $\geq 50\%$  versus 80 years in TS  $<50\%$ ). Results were similar in men, in late-onset type 1 diabetes (cohort I), in any type 1 diabetes, and onset at age  $\geq 30$  years, respectively. Results were not significant in women, in cohort II, in type 2 diabetes, other diabetes, or onset at age  $<30$  years, respectively. In cohort I, cumulative survival was decreased in those with genotype C282Y/C282Y versus wild type/wild type in men (log-rank  $P=0.0001$ , adjusted HR 10.0 (3.5–28.1;  $P<0.001$ ), PAR 13%, and median survival 56 years in C282Y/C282Y versus 79 years in

wild type/wild type). In cohort I, cumulative survival for the combined exposure (TS  $\geq 50\%$  plus C282Y/C282Y) versus (TS  $<50\%$  plus wild type/wild type) in men was decreased (log-rank  $P<0.0001$ , adjusted HR 10.4 (3.7–29.3;  $P<0.001$ ), PAR 13%, and median survival 56 years in (TS  $\geq 50\%$  plus C282Y/C282Y) versus 79 years in (TS  $<50\%$  plus wild type/wild type)). No women with C282Y/C282Y died during follow-up.

**Conclusion:** Patients with diabetes with increased TS and/or hemochromatosis genotype have an increased risk of premature death, but most so in men with a 10-fold risk and with 23 years reduced life span. Two to thirteen percent of premature death among diabetics can be avoided with early screening for TS and hemochromatosis genotype.

### 345

#### Serum proenkephalin A and mortality in patients with type 2 diabetes (ZODIAC-32)

J.F.H. Arnold<sup>1</sup>, K.J.J. van Hateren<sup>1</sup>, K.H. Groenier<sup>1,2</sup>, G.J. Navis<sup>3</sup>, J. Struck<sup>4</sup>, S.J.L. Bakker<sup>3</sup>, N. Kleefstra<sup>1,3</sup>, H.J.G. Bilo<sup>1,3</sup>

<sup>1</sup>Diabetes Centre, Isala Clinics, Zwolle, Netherlands, <sup>2</sup>General Practice, University Medical Center Groningen, Netherlands, <sup>3</sup>Internal Medicine, University Medical Center Groningen, Netherlands, <sup>4</sup>Research Department, B.R.A.H.M.S GmbH (Thermo Fisher Scientific), Hennigsdorf/Berlin, Germany.

**Background and aims:** Enkephalins are endogenous opioid peptides derived from the precursor hormone proenkephalin A. These peptides have been found in the pancreatic islets and have been suggested to play a role in glucose metabolism. In addition, opioid peptides are also involved in a variety of cardiovascular pathways, and can e.g. influence blood pressure. Therefore, we aimed to investigate whether Proenkephalin A (PENK-A) was related to all-cause and cardiovascular mortality in patients with type 2 diabetes mellitus (T2DM).

**Materials and methods:** This study is part of the ZODIAC study, a prospective observational study of primary care patients with T2DM, and incorporates two cohorts (1998 and 2001) with a number of 1689 patients. EDTA plasma was stored at  $-80^{\circ}\text{C}$ , until assessment of PENK-A by sandwich immunoassay. Data on mortality were collected in 2009. Primary endpoints were all-cause and cardiovascular mortality. Cox-proportional hazards models were used to investigate the relationship between PENK-A and mortality with adjustment for selected confounders. Three models were chosen: model 1 included only PENK-A, model 2 included age and sex and model 3 included 9 cardiovascular risk factors as additional potential confounders. Harrell C statistic was used to investigate the capability of each model to predict mortality. PENK-A was logarithmically transformed because of skewed distribution of the data.

**Results:** PENK-A was assessed in baseline serum samples of 1204 patients; age  $66.8 \pm 11.6$  years, 45.2% males, with a median [interquartile range] PENK-A concentration of 112.0 [91.2–143.0] pmol/l. Other baseline data include mean HbA1c of  $55.6 \pm 9.0$  mmol/mol and a median diabetes duration of 4 [2–9] years. During a median follow-up period of 5.5 [3.1–10.1] years, 361 (30.0%) patients had died of which 153 (42.4%) were attributed to a cardiovascular cause. Table 1 presents the hazard ratios (HR) of log PENK-A for mortality and the Harrell C's for the three models, showing an increased HR for mortality for the crude model, and after adjustment for age and gender. However, in model 3, the association of log PENK-A with mortality lost its significance. According to the Harrell C statistic, model 3 is the most capable for predicting mortality. Removing PENK-A from model 2 and 3 yielded no significant change in the prediction of mortality and no relevant change in Harrell's C values.

Table 1:

Primary endpoints	Model 1	Model 2	Model 3
<b>All-cause mortality</b>			
log PENK-A: HR (95% CI)	3.78 (2.80–5.11)	1.54 (1.11–2.13)	1.31 (0.91–1.89)
Harrell's C (95% CI)	0.63 (0.59–0.66)	0.77 (0.75–0.80)	0.80 (0.78–0.82)
<b>Cardiovascular mortality</b>			
Log PENK-A: HR (95% CI)	5.51 (3.49–8.69)	2.70 (1.62–4.51)	1.61 (0.90–2.87)
Harrell's C (95% CI)	0.65 (0.60–0.70)	0.75 (0.71–0.80)	0.81 (0.78–0.85)

**Conclusion:** Increased levels of PENK-A were associated with an increased risk of all-cause and cardiovascular mortality in type 2 diabetes, even after adjusting for gender and sex. However, after adjustment for several cardiovascular risk factors this significant association was no longer observed.

## PS 010 Burden of diabetes and approaches to decrease it

346

### Trends in epidemiology and costs of diabetes in Italy. The ARNO observatory database

R. Miccoli, On behalf of the SID-CINECA “ARNO-Diabetes” Working Group;

Department of Endocrinology and Metabolism, Pisa University, Pisa, Italy.

**Background:** Accurate data about the magnitude and distribution of diabetes mellitus can inform policy and support health care evaluation. By using physician prescriptions and other administrative data we aimed to describe trends in incidence and prevalence of diabetes in Italy over time.

**Materials and methods:** The ARNO-Diabetes is a data base comprising 9,465,492 citizens resident in 29 Local Health Districts (LHD) during 2010 and a large cohort of 2,135,494 living in 10 LHD with data spanning from 1997 to 2010. Three administrative databases with record linkage were used in the present analysis.

**Results:** In the 2010, 544,852 patients with diabetes (49% female, F; 51% male, M), were identified by using drug prescription data (88%), hospital records (ICD-9)(15%) and exemptions from medical charge (76%). Prevalence of disease was 5.8% (F 6.1%, M 5.5%) with an increasing gradient from northern to southern Italian areas. Nearly two third of cases were aged over 64, with one third being over 80. Only 0.5 and 2% of cases were below 19 and 34, respectively. Twelve percent of patients were on diet only, 67% were being treated with oral antidiabetic drugs (OAD), 10% with OAD+insulin, 11% with insulin alone. The prevalence of diabetes increased steadily from 2.8% in 1997, particularly in M (+87% vs. +52% in F) with an annual incidence of 7 cases per 1000 persons-year. Drug treatment represented only 1/3 of total cost attributed to diabetes, with an increase of 132% in the same period. A 97% increase of cost has been registered for OAD while that for insulin was 184%, respectively.

**Conclusion:** During the last 15 years a significant increase in diabetes prevalence occurred in Italy, with a corresponding rise of costs. The combined use of different administrative databases is a feasible and efficient method to determine and monitor the incidence, prevalence and costs of diabetes.

### Demographic modelling of the direct medical excess costs of type 2 diabetes mellitus in Germany from 2010 to 2040

R. Waldeyer<sup>1,2</sup>, R. Brinks<sup>2</sup>, W. Rathmann<sup>2</sup>, G. Giani<sup>2</sup>, A. Icks<sup>1,2</sup>;

<sup>1</sup>Public Health Department, Faculty of Medicine, Heinrich Heine University, Düsseldorf, <sup>2</sup>Institute for Biometry and Epidemiology, German Diabetes-Center, Düsseldorf, Germany.

**Background and aims:** Comprehensive analyses of the future course of diabetes-related costs in Germany are lacking. We model a country-specific forecast of direct medical costs of type 2 diabetes. Demographic changes, disease dynamics and undetected cases are taken into account. Consequences of hypothetical population-based preventive interventions are analyzed.

**Materials and methods:** A time-discrete Markov model is developed to estimate stratum-specific future prevalences of diabetes (diagnosed/undetected) 2010–2040 in the population over 40 years. They are linked with cost weights. Demographic, epidemiologic, and economic scenarios are modelled. Model inputs include the official population forecasts, current prevalences, incidences, mortalities, proportions of undetected cases, per capita health expenditures of the general population, and cost ratios of a person without diabetes vs. a diabetic person (diagnosed/undetected). Model outputs are the numbers of cases and the associated annual direct medical excess costs of type 2 diabetes (in 2010€) from a societal perspective.

**Results:** In the base case, case numbers rise steeply until 2030. Then the growth levels off until the maximum of 8.0 million diseased people is reached in 2037 (of which 3.4 million are undetected). The prevalence of over 40-year-olds increases from 10.6% in 2010 to 16.1% in 2040. The numbers of cases decrease in age groups under 60 and more than double in age groups over 75 years. The annual costs increase from 2010 (11.9 billion Euros) to 2030 by 74%. The growth rate gets smaller afterwards. In 2040, costs of 21.1 billion Euros are expected (Figure). In the scenario of constant prevalences over time, costs in-

crease to 15.1 billion Euros. The results are sensitive to rising per capita costs, too. They do not vary a lot due to demographic scenarios and proportions of undetected cases. If a prevention to lower the incidence by 10%, 20%, 30%, resp. 40% would be established over the next 10 years, it would lead to cumulative savings of 25, 51, 77, resp. 105 billion Euros in diabetes-related health expenditures from 2010 to 2040 (not including intervention costs), see Figure.

**Conclusion:** The projected increase in cases over the next 30 years is due to demographic changes and disease-dynamics. It is enhanced by higher per capita costs with age, causing a stronger growth rate of the predicted costs. Better epidemiologic and economic data of diabetes care in Germany is needed to improve the forecasting accuracy. Nevertheless, the results suggest a continuing rise in diabetes-related health expenditures. The hypothetical potential of prevention is shown and needs to be further evaluated in cost-effectiveness analyses. The forecasting method can be developed further to anticipate possible impacts of alternative policy scenarios of prevention and intervention. It can easily be adapted to other chronic diseases as well.

348

### Who are caring for patients with childhood-onset adult type 1 diabetes in Japan? Paediatric or adult diabetologists? The DERI mortality study

Y. Onda<sup>1</sup>, A. Morimoto<sup>1</sup>, R. Nishimura<sup>1</sup>, H. Sano<sup>1</sup>, K. Utsunomiya<sup>1</sup>, N. Tajima<sup>2</sup>;

<sup>1</sup>Department of Internal Medicine Division of Diabetes and Endocrinology,

<sup>2</sup>The Jikei University School of medicine, Tokyo, Japan.

**Background:** The timing for transition of patients with childhood-onset type 1 diabetes (T1D) from pediatric (PED) to adult diabetology (AD) has become the subject of debate in recent years, which led to a position statement being released by the ADA transition working group, and this topic is also being hotly debated in Japan, where it is not rare that these patients continue to consult PED even after attaining adulthood.

**Objective:** To investigate the status of care for patients with T1D by their attending physicians, 25 years after diagnosis.

**Methods:** Of the 1,387 patients (556 males/831 females) registered with two nationwide T1D surveys in Japan who were diagnosed as having T1D at less than 18 years of age between 1965 and 1979, the present study included a total of 859 patients (330/529) whose attending physicians were confirmed as of January 1, 2000. Their attending physicians and affiliations were determined based on completed questionnaires. We evaluated the percentage of the attending physicians as they were accounted for by PED, AD, and other specialists (OS). We also investigated factors that contributed to these patients consulting PED by using the logistic regression model with the age at diagnosis, sex, and the calendar year of diagnosis included as predictive variables. All statistical analyses were performed by using SAS 9.2.

**Results:** The mean age at diagnosis of the 859 patients was  $8.5 \pm 4.1$  (SD) years, with a duration of diabetes  $25.2 \pm 4.0$  years. Their mean attained age as of January 1, 2000 was  $33.7 \pm 5.8$  years. Of these, 16.4% (141 patients, 57 males/84 females) consulted PED, 81.3% (698, 266/432) consulted AD, and 2.3% (20, 7/13) consulted OS. By their age at diagnosis, of the 667 patients

diagnosed at less than 12 years old, 19.5% consulted PED, 78.7% AD, and 1.8% consulted OS, while, of those diagnosed at 12 years old or older (192 patients), 5.7% consulted PED, 90.1% AD, and 4.1% OS. Significantly more patients consulted PED among those diagnosed at less than 12 years old than among those diagnosed at 12 years old or older ( $P < 0.001$ , chi-square test). There was no significant sex difference by age of diagnosis in the percentage of those who consulted PED. By their attained age, of the 244 patients whose attained age was less than 30 years old, 29.1% consulted PED, 68.9% AD, and 2.1% OS. Of the 615 patients whose attained age was over 30 years old, 11.4% consulted PED, 86.2% AD, and 2.4% OS. Significantly more patients consulted PED among those whose attained age was less than 30 years old than among those whose attained age were over 30 years old ( $P < 0.001$ ). There was no significant sex difference by attained age in the percentage of those who consulted PED. Logistic regression analyses revealed that younger age at diagnosis and more recent year of diagnosis but not sex were significant predictors of these patients consulting PED.

**Conclusion:** Even 25 years after diagnosis, 16.4 % of Japanese patients with childhood-onset adult T1D consulted PED. Significantly more patients consulted PED among those diagnosed at less than 12 years old and those whose attained age were less than 30 years old, compared with those diagnosed at 12 years old or older and those whose attained age was over 30 years old. About 10% of patients over 30 years of age still consulted PED.

#### Health-related quality of life in type 2 diabetes patients taking oral anti-diabetic drugs in urban China

W. Jia<sup>1</sup>, Y. Shen<sup>2</sup>, J. Lu<sup>3</sup>, J. Weng<sup>4</sup>, L. Ji<sup>5</sup>, China DiaSTAGE Study Group;

<sup>1</sup>Shanghai Jiao Tong University Affiliated 6th People's Hospital, Shanghai,

<sup>2</sup>Zhejiang University School of Medicine, Hangzhou, <sup>3</sup>Chinese People's Liberation Army General Hospital, Beijing, <sup>4</sup>Sun Yat-sen University 3rd Hospital, Guangzhou, <sup>5</sup>Peking University People's Hospital, Beijing, China.

**Background and aims:** To understand the health-related quality of life (HRQoL) among type 2 diabetes (T2D) patients taking oral anti-diabetic drugs (OAD) and its associated determinants in Urban China.

**Materials and methods:** A nationwide, cross-sectional, multicenter study was conducted between Jun - Nov 2010. A total of 9872 patients with T2D were recruited from 103 centers. A standardized case report form was used by on-site physicians to collect and record patient data, including socio-demographic characteristics, disease profile and treatment pattern. Patient's HRQoL was assessed by visual analog scale (VAS) and EuroQol-5 Dimensions (EQ-5D). Logistic regressions and linear regressions were used to explore determinants of responses in the EQ-5D dimensions.

**Results:** 2805 patients had well-controlled blood-glucose ( $HbA1c < 6.5$ ), accounting for 28.63% of the study population. Average VAS and EQ-5D score were  $78.59 \pm 11.45$  and  $0.810 \pm 0.081$ , respectively. The percentages of patient reporting "no problem" in five dimensions were high in the middle and low in both ends along the corresponding HbA1c level ( $< 6.5$ ,  $6.5-7.5$ ,  $> 7.5$ ). The probability of reporting "problems" in Mobility dimension was 1.72-fold ( $P = 0.0091$ ) in blood-glucose uncontrolled group compared to that in well-controlled group. VAS and EQ-5D scores were lower in uncontrolled group ( $78.07 \pm 11.45$ ,  $0.807 \pm 0.083$ ,  $P < 0.0001$ ) than in well-controlled group ( $79.82 \pm 11.30$ ,  $0.817 \pm 0.074$ ,  $P < 0.0001$ ). Course of disease was weakly correlated with VAS and EQ-5D scores, with negative correlation coefficient of  $-0.04$  ( $P = 0.0003$ ) and  $-0.13$  ( $P < 0.0001$ ). Hypoglycemia increased the probability of reporting "problems" in 4 dimensions except for Mobility. Patients with hypoglycemia had a lower EQ-5D score compared to patients without hypoglycemia ( $0.792 \pm 0.098$  VS  $0.813 \pm 0.078$ ,  $P < 0.0001$ ), but found no such impact on VAS scores. Average BMI in T2D patients was  $24.50 \pm 2.96$ . BMI was negatively associated with the probability of reporting "problems" in Anxiety/Depression dimension ( $P = 0.0007$ ) but was positively correlated with VAS and EQ-5D scores ( $P < 0.0001$ ,  $P < 0.0072$ , respectively). Complications increased the probability of reporting "problems" in all five dimensions ( $P < 0.0001$ ). The strongest determinants of increased problem reporting were stroke and diabetic foot. VAS and EQ-5D scores were lower in patients with complications ( $78.40 \pm 11.57$ ,  $0.807 \pm 0.084$ ) compared to patients without ( $81.42 \pm 9.73$ ,  $0.832 \pm 0.047$ ) ( $P < 0.0001$ ).

**Conclusion:** Well-controlled blood-glucose is associated with improved HRQoL in T2D patients while hypoglycemia, lower BMI and complications may have substantial negative impact on several dimensions of HRQoL.

Table 1. EQ-5 Dimensions and VAS scores at different HbA1c level

Dimensions	Statements	HbA1c(%)			X <sup>2</sup>	P value
		<6.5	6.5-7.5	>7.5

Centre in the Li Ka Shing Knowledge Institute of St. Michael's Hospital, Toronto, Canada.

**Background and aims:** Lifestyle modification is an important cornerstone for the management of type 2 diabetes (T2D). We determined the prevalence of engagement in lifestyle behavior change, as well as the impact of healthcare professional support on these behaviors using national-level data.

**Materials and methods:** Self-reported data was available from 2682 adult patients with T2D, age 20 years or older, who responded to the 2011 Survey on Living with Chronic Diseases in Canada's diabetes component. Multivariate prevalence rate ratios (RR) for never engaging in, and not sustaining self-management behaviors (of dietary change, weight control, exercise, and smoking cessation) were evaluated using binomial regression models.

**Results:** The prevalence of reported dietary change, weight control/loss, increased exercise and smoking cessation (among those who smoked since being diagnosed), were 89.7%, 72.1%, 69.5%, and 30.6%, respectively. Participants who reported not receiving health professional advice were more likely to report never engaging in dietary change (RR = 2.7, 95% CI 1.8 - 4.2), exercise (RR = 1.7, 95% CI 1.3 - 2.1), or weight control/loss (RR = 2.2, 95% CI 1.3 - 3.6), but not smoking cessation (RR=1.0, 95% CI 0.7, 1.5). Also, living with diabetes for more than six years was associated with not sustaining dietary change, weight loss and smoking cessation, but not exercise.

**Conclusion:** Health professional advice may support individual action for lifestyle behaviors for T2DM self-management. Patients living with the disease for more than 6 years may require additional support in sustaining recommended behaviors.

#### Response to tailored therapy in a heterogeneous type 2 diabetes mellitus population: simulation results from a qualified mathematical model

A. De Gaetano<sup>1</sup>, S. Panunzi<sup>1</sup>, T.A. Hardy<sup>2</sup>;

<sup>1</sup>Biomathematics Lab, Cnr Iasi, Rome, Italy, <sup>2</sup>Eli Lilly & Company,

Indianapolis, USA.

**Background and aims:** Disease heterogeneity in T2DM is manifest in multiple ways, including age of onset, rate of disease progression, risk of complications, and response to available therapies. Tailored therapeutics (TTx) involves matching treatment options to individual patient characteristics with the goal of maximizing the benefit/risk ratio. In the current work, we have used a mechanistic mathematical model of T2DM long-term evolution (Diabetes Progression Model, DPM) to explore TTx hypotheses. DPM has previously been shown to faithfully simulate the natural progression of T2DM over several years, and to recapitulate the effects of various interventions represented in the Diabetes Progression Program and CANOE studies.

**Materials and methods:** The evolution of fasting glycemia, fasting insulinemia and beta-cell mass were simulated for virtual patients with a range of defects in insulin secretion, insulin sensitivity, or both. For each hypothesized time course of the primary defects or their combination, the natural history of the disease as well as the response to several interventions or sequences of interventions were simulated. Among the therapeutic approaches tested are pharmacologic interventions directed at improving insulin sensitivity and insulin secretion proportionally to underlying metabolic status and secretory ability, as well as radical maneuvers hypothetically restoring a fraction of normal sensitivity or secretion, such as metabolic/bariatric surgery or successful elimination of inflammation-induced inhibition of beta-cell replication. Results were compared to available published information.

**Results:** Response to individual therapies is influenced not only by the degree of insulin resistance or insulin secretory defect, which is a function of the type and stage of progression of the original abnormality, but also by the accumulated injury to beta-cell replicating ability, which depends on the duration and severity of the primary defect. Therapy directed at proportional improvement of the current insulin sensitivity or secretion levels has largely equivalent effects, independent of the nature of the original defect. This effect lacks durability if started after development of hyperglycemia. Durable results can be obtained with drastic and permanent lifestyle changes or by administering conventional therapy as soon as reasonable suspicion of deteriorating insulin sensitivity or secretion is entertained.

**Conclusion:** Tailored therapeutic approaches can be explored prospectively, for a given patient, by the use of diabetes progression model simulations, detailing response to interventions based on therapeutic mechanism and underlying pathophysiology. For patients with advanced degrees of insulin sensitivity or secretion defects, simulations are consistent with clinical observation in predicting short-lived efficacy of conventional pharmacologic treatment. More articulate TTx schemes can however be designed, their likely efficacy evaluated over a realistically heterogeneous population of virtual subjects, and promising approaches, with improved benefit/risk ratios, can then be tested in real-world clinical trials.

interventional programme was 686€ compared to 646€ in the non intervention group. The incremental cost of the individual and group intervention compared to the standard preventive care was 10€ and 106€ and the incremental cost-effectiveness ratio (ICER) was 746€ and 108€ per averted case of diabetes, respectively. The QoL (utility) at the end of study was higher for the intervention group (0.93 vs. 0.91) when compared to the control cohort ( $p=0.01$ ), being the incremental cost-utility ratio 3243 €/QALY gained. At the sensitivity analysis, costs were very sensible to different sources of costing though remaining at an acceptable level. Limitations of the study include the variability of healthcare resource usage and not having included the induced resource usage.

**Conclusion:** Taking into account the costs of managing patients with diabetes, this study shows that a PHC led intensive lifestyle intervention among high-risk people is not only effective but also efficient in delaying progression to diabetes. The future implementation of this model could be highly recommended.

### Efficiency of a community based intervention on high risk individuals for developing diabetes. The PREDICE & DE-PLAN-CAT study

J.J. Cabre<sup>1</sup>, O. Solà-Morales<sup>2</sup>, B. Costa<sup>1</sup>, B. Sunyer<sup>3</sup>, R. Sagarra<sup>1</sup>, F. Barrio<sup>1</sup>, B. Bolibar<sup>1</sup>, C. Castell<sup>4</sup>;

<sup>1</sup>Diabetes & Metabolism, Jordi Gol Primary Care Research Institute, Reus-Barcelona, <sup>2</sup>Chief Medical Director, SabirMedical, Barcelona, <sup>3</sup>Catalan Agency for Health Information, Assessment and Quality, Barcelona,

<sup>4</sup>Department of Health, Barcelona, Spain.

**Background and aims:** One of the main tasks of primary health care (PHC) is to implement strategies leading to improve efficiently the care of the population. It is well known that individuals at high risk, particularly those diagnosed as having prediabetes, tend to progress to Type 2 diabetes. We have previously shown that a PHC lifestyle intervention is effective in delaying progression to diabetes among high-risk individuals. The objective of this study was to show that the strategy is also efficient.

**Materials and methods:** Data on resource utilisation and quality of life (QoL) were collected alongside a prospective cohort study conducted in 18 PHC centres evaluating the effectiveness of an intensive lifestyle intervention. People were eligible for the lifestyle intervention only if they had had an oral glucose tolerance test, did not have diabetes and had either or both of a FINDRISC score  $\geq 14$  or prediabetes (WHO criteria for fasting or 2 h glucose). Where feasible, high-risk identified individuals were allocated sequentially to standard care, a group-based or an individual level intervention (intensive reinforced DE-PLAN intervention). Details of the individual resources used (physician and nursing time, number of visits...) were collected during the trial on a random subsample of the cohort. Average costs were calculated using the apportioned costing data recorded. The incidence of diabetes was considered the primary effectiveness outcome but also QoL which was captured periodically using the 15D questionnaire till participants developed diabetes. The results were converted into utility measures. Costs and QoL differences were analysed and a cost-effectiveness analysis was then performed.

**Results:** The incidences of diabetes after 4.2 years median follow-up were 4 and 3.6 cases per 100 person-years for both group ( $n=230$ ) and individual ( $n=103$ ) intensive interventions and 7.2 per 100 person-years in the standard-care ( $n=219$ ) control group. The cumulative incidence after 4 years follow-up was 20% and 14.6% for both group and individual intervention and 28.8% in the standard care group. The average costs per person of the

### Diabetes prevalence among 2.4 million Health Maintenance Organisation (HMO) members < 20 years of age, 2005–2009: the SUPREME-DM project

J.M. Lawrence<sup>1</sup>, P.J. O'Connor<sup>2</sup>, J.R. Desai<sup>3</sup>, R.J. Reid<sup>3</sup>, E. Schroeder<sup>4</sup>, S. Vupputuri<sup>5</sup>, X.S. Yan<sup>6</sup>, J.F. Steiner<sup>4</sup>, G.A. Nichols<sup>7</sup>, for the SUPREME-DM Study Group;

<sup>1</sup>Kaiser Permanente Southern California, Pasadena, <sup>2</sup>HealthPartners Research Foundation, Minneapolis, <sup>3</sup>Group Health Cooperative, Seattle, <sup>4</sup>Kaiser Permanente Colorado, Denver, <sup>5</sup>Kaiser Permanente Southeast, Atlanta, <sup>6</sup>Geisinger Health System, Danville, <sup>7</sup>Kaiser Permanente Northwest, Portland, USA.

**Background and aims:** Despite the growing concern about the incidence and prevalence of diabetes mellitus (DM) among youth, few data sources allow for the tracking of U.S. cases on a population level. Electronic health records (EHR) provide an opportunity to identify persons with DM in large diverse populations. We estimated annual DM prevalence by age category and sex over 5 years, 2005–2009, among members of 11 HMOs from 10 U.S. States who were <20 years of age.

**Materials and methods:** For each year, the denominator was composed of health plan members < 20 years of age on the last day of the year with ≥ 6 months of health plan membership. The numerator included individuals with ≥ 2 laboratory test results indicative of DM, ≥ 1 inpatient or ≥ 2 outpatient DM diagnoses, or dispensed any glucose-lowering medication other than metformin, outside of any pregnancy period. We estimated DM prevalence/1,000 members by age and sex, and calculated absolute rate change and % change from 2005 to 2009. We report glucose-lowering medication use for youth ≥ 10 years, categorized as insulin only (probable type 1), oral agent ± insulin (probable type 2), and no medications (probable type 2 or undiagnosed DM).

**Results:** The average annual denominator was 2,406,796 HMO members < 20 years of age. DM prevalence increased by 9.1%, from 2.70/1,000 in 2005 to 2.95/1,000 in 2009 (Table). Increases were observed among youth 5–9 years (15.6%), 10–14 years (8.2%) and 15–19 years (11.8%) with a 19.4% decline among youth < 5 years. Among 10–14 year olds, increases were seen in the oral agent ± insulin group and among those not using medications. Among 15–19 year olds, increases were seen in all three treatment groups, with the largest absolute and relative increases among insulin users. DM prevalence was higher for girls than boys for all years (e.g., 3.00/1,000 for girls vs. 2.77/1,000 for boys in 2009). Among youth ages 10 and older, girls with DM were more likely than boys to be in the insulin only group.

**Conclusion:** Using EHR data from members of 11 geographically dispersed HMOs; we found that the prevalence of DM was higher than previously reported for U.S. youth. This may be due to differences in the populations under surveillance, approaches to case ascertainment and definition, the inclusion of undiagnosed cases, or an increase in DM prevalence in recent years. Prevalence was higher for girls than for boys, a finding observed in other studies. The rise in probable type 2 DM prevalence among 10–14 year-olds is of particular concern. EMRs provide a cost-effective opportunity to provide sustainable nation-wide childhood diabetes surveillance.

Age, Years	Mean Annual Denominator/ Medication Category	2005	2006	2007	2008	2009	Absolute 5-Year Change	% 5 Year Change

### Long-term patterns of HbA<sub>1c</sub> among patients with type 2 diabetes mellitus

E.J.F. Lamberts<sup>1</sup>, M.L. Bouvy<sup>1</sup>, P.C. Souverein<sup>1</sup>, G. Nijpels<sup>2</sup>, L.M.C. Welschen<sup>3</sup>, J.M. Dekker<sup>2</sup>, J.G. Hugtenburg<sup>3</sup>, E. van 't Riet<sup>2</sup>;

<sup>1</sup>Division of Pharmacoepidemiology and Pharmacotherapy, Utrecht Institute for Pharmaceutical Sciences, <sup>2</sup>Department of General Practice and the EMGO Institute for Health and Care Research, Amsterdam, <sup>3</sup>Department of Clinical Pharmacology and Pharmacy, Amsterdam, Netherlands.

**Background and aims:** Treatment guidelines recommend in general strict glycemic control. HbA<sub>1c</sub> (glycosylated hemoglobin) has been used as a marker for glycemic control. Maintaining appropriate HbA<sub>1c</sub> levels and lowering cardiovascular risk factors have proven to decrease micro vascular and macro vascular disease. Identifying long-term trends and predictors of glycemic control may enable clinicians to identify patients at risk of inadequate glycemic control. The objective of this study was to determine longitudinal HbA<sub>1c</sub> categories in daily clinical practice of patients with type 2 diabetes and to identify predictors of these categories.

**Methods:** A retrospective observational cohort study was conducted among patients with type 2 diabetes. Data were obtained from a protocolled Diabetes Care System (DCS), situated in West-Friesland, The Netherlands, a region that has approximately 200,000 inhabitants and is representative for a Dutch and Western-European population. All annually measured clinical data, including HbA<sub>1c</sub>, were registered in a central database. For each patient, linear regression analysis was conducted starting from the second HbA<sub>1c</sub> measurement to the end of follow-up. The slope of the regression line ( $\beta$ -coefficient) was used as an indicator for the individual time trend of the HbA<sub>1c</sub> progress. Patients were classified as either deteriorating ( $\beta$ -coefficient > +0.1), improving ( $\beta$ -coefficient < -0.1) or stable ( $\beta$ -coefficient between -0.1 and +0.1). Logistic regression analysis was used to calculate the odds ratios of the potential predictors for HbA<sub>1c</sub> deterioration with combined improving and stable categories as reference category with 95% confidence intervals. Crude and adjusted odds ratios were calculated. Adjustment was done for all the predictors in the total model. We stratified for age category at baseline to assess HbA<sub>1c</sub> progress up to seven years of treatment.

**Results:** We included 4,689 patients in the study cohort. HbA<sub>1c</sub> levels in the youngest group (35–45 years) increased more strongly compared to the older age groups who tended to stabilize at sub clinical levels of 7.5% (58 mmol/mol), while the 45–54 age category stabilizes at 7.2% (55 mmol/mol). Younger age was associated with an increased risk of deterioration compared to older age (adjusted odds ratio 1.44 (95% CI: 1.04–1.99)).

**Conclusion:** Patients with younger age at baseline are more likely to be in the deteriorating HbA<sub>1c</sub> category. Our findings recommend more intensive monitoring and treatment of younger patients. More research is needed for a better understanding of the relationship between younger age and long term increase in HbA<sub>1c</sub>.

Mean HbA<sub>1c</sub> by age category shown per year of treatment in the Diabetes Care System (DCS)

## 355

**Relative contribution of insulin resistance and insulin deficiency in the development of type 2 diabetes in Koreans**C.-H. Kim<sup>1</sup>, H.-K. Kim<sup>2</sup>, E.-H. Kim<sup>2</sup>, S.-J. Bae<sup>2</sup>, J.-Y. Park<sup>3</sup><sup>1</sup>Internal Medicine, Soonchunhyang University Bucheon Hospital, Bucheon, Kyeonggi-do, <sup>2</sup>Health Screening & Promotion Center, Asan Medical Center, Seoul, <sup>3</sup>Internal Medicine, University of Ulsan College of Medicine, Seoul, Republic of Korea.

**Background and aims:** Type 2 diabetes is a heterogeneous disorder characterized by varying degrees of insulin resistance and relative insulin deficiency. However, it is still unclear whether the relative contribution of insulin resistance and beta-cell dysfunction in the pathogenesis of type 2 diabetes differs by ethnicity. We assessed indices of insulin resistance and beta-cell function in non-diabetic Korean individuals and examined their association with later development of type 2 diabetes.

**Materials and methods:** We analyzed the clinical and laboratory data of 17,878 Korean adults (age 20–79 years, 11,218 men and 6,660 women) who underwent routine medical check-ups in 2007–08 (baseline) and again in 2010–11 (follow up) with a mean 3.5-year (range 2.5–4.5 years) interval. All non-pregnant adults who did not have diabetes at baseline examination were included for the analysis. Insulin resistance (HOMA-IR) and beta-cell function (HOMA-%B) indices at baseline were assessed by homeostasis model assessment. The presence of insulin resistance and beta-cell dysfunction were defined as HOMA-IR  $\geq 75$  percentile and HOMA-%B  $\leq 25$  percentile values of non-obese participants who had normal fasting glucose levels and no metabolic syndrome ( $n=9525$ ). Odds ratios (ORs) for incident type 2 diabetes were estimated using multiple logistic regression analysis.

**Results:** Among the 17,878 participants who did not have diabetes at baseline, a total of 732 subjects (4.1%, 571 men and 161 women) developed type 2 diabetes during the 3.5-year follow-up period. Those who developed type 2 diabetes had significantly higher fasting serum insulin level ( $8.9 \pm 5.2$  vs.  $6.9 \pm 3.9$  mU/l,  $P < 0.001$ ) and HOMA-IR ( $2.38 \pm 1.45$  vs.  $1.65 \pm 1.02$ ,  $P < 0.001$ ), and low HOMA-%B ( $74 \pm 47$  vs.  $85 \pm 48$ ,  $P < 0.001$ ) at baseline. The cut-off values for insulin resistance and beta-cell dysfunction were HOMA-IR  $\geq 1.72$  (75th centile) and HOMA-%B  $\leq 53$  (25th centile), respectively. Among the subjects who developed type 2 diabetes, 29% showed predominant beta-cell dysfunction, 51% had predominant insulin resistance, and 10% had combined defects. When we divided the participants according to the median BMI of the whole population at baseline ( $23.7 \text{ kg/m}^2$ ), 49% had predominant beta-cell dysfunction and 26% had predominant insulin resistance in lower BMI group, while 21% had mainly beta-cell dysfunction and 60% had mainly insulin resistance in the higher BMI group. The odds ratio of incident type 2 diabetes for the insulin resistance (HOMA-IR  $\geq 75$  percentile vs.  $< 75$  percentile) was 4.23 (95% CI, 3.35–5.34), and that for the beta-cell dysfunction (HOMA-%B  $\leq 25$  percentile vs.  $> 25$  percentile) was 5.31 (4.21–6.71) after adjustment for age, gender, BMI, alcohol consumption, smoking status, physical activity, and family history of diabetes.

**Conclusion:** These results suggested that the primary pathogenetic factor of type 2 diabetes in Korean is heterogeneous with varied contribution of insulin resistance and beta-cell dysfunction according to BMI. In subjects with lower BMI, beta-cell dysfunction is the predominant defect, while insulin resistance is the predominant pathogenetic factor in subjects with higher BMI in the development of type 2 diabetes.

## 356

**Evidence for different subtypes of type 2 diabetes: prospective analysis of the Whitehall II study**K. Færch<sup>1</sup>, D.R. Witte<sup>1,2</sup>, A.G. Tabák<sup>2,3</sup>, E.J. Brunner<sup>2</sup>, M. Kivimäki<sup>2</sup>, D. Vistisen<sup>1</sup><sup>1</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>2</sup>Department of Epidemiology and Public Health, University College London, UK, <sup>3</sup>Department of Medicine, Semmelweis University, Budapest, Hungary.

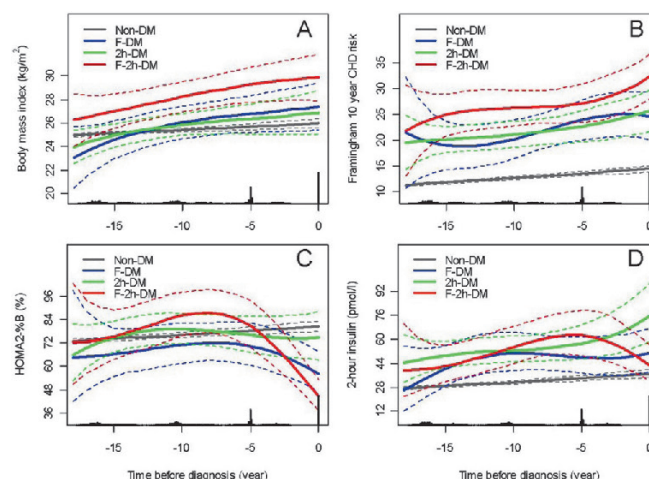

**Background and aims:** Underlying individual differences in physiology may occur early in the pathogenesis of type 2 diabetes. We determined whether different subgroups of type 2 diabetes based on the type of diagnostic glucose value exhibit different trajectories of metabolic features before the time of diagnosis.

**Methods:** Data from the prospective Whitehall II cohort were used. The study included 274 individuals who developed screen-detected type 2 diabetes over 18 years. These patients were divided into subgroups based on

their fasting and 2-hour glucose concentration at the time of diagnosis as: 1) elevated fasting glucose only (F-DM,  $n=55$ ); 2) elevated 2-hour glucose only (2h-DM,  $n=148$ ); and 3) both elevated fasting and 2-hour glucose (F-2h-DM,  $n=71$ ). Individuals without diabetes during the study were included as reference group ( $n=6,569$ ). Trajectories of measures of glucose metabolism, body mass index (BMI), and estimated risk of coronary heart disease (CHD, Framingham score) up to the time of diagnosis were studied using growth curve mixed-effects models with cubic term for time and adjusting for age, sex, ethnicity and study phase.

**Results:** The shapes of the trajectories for BMI and CHD risk were similar for all three diabetes groups, however with higher levels of BMI ( $P < 0.05$ ; Fig. 1A) and CHD risk ( $P \leq 0.002$ , Fig. 1B) in patients diagnosed by F-2h-DM. Interestingly, patients diagnosed by F-DM had a stable but low beta cell function more than a decade before their clinical diagnosis, whereas those with F-2h-DM exhibited an increased beta cell function 7–8 years before diagnosis, followed by a loss of beta cell function up to the date of diagnosis ( $P < 0.001$ ; Fig. 1C). Individuals who developed 2h-DM had slightly increasing 2-hour insulin concentration up to the time of diagnosis, whereas those with F-2h-DM experienced a fall in 2-hour insulin concentration a few years prior to their diagnosis ( $P < 0.001$ ; Fig. 1D).

**Conclusion:** Patients with type 2 diabetes show different trajectories of metabolic parameters before diagnosis based on whether they are diagnosed by elevated fasting glucose, 2-hour glucose or both, suggesting that their underlying pathophysiology may be different. These findings question whether a “one size fits all” prevention strategy can be equally effective for all people with a high risk for diabetes.

**Figure 1** Trajectories of BMI (A), 10-year risk of coronary heart disease (B), homeostasis model assessment of beta cell function (C), and 2-hour postload insulin (D) in individuals who develop different subtypes of diabetes as well as of individuals who do not develop diabetes during the study period of 18 years. Models are adjusted for age, sex, ethnicity and study phase.

Clinical Trial Registration Number: NCT00005680

## 357

**Sex difference in trajectories of glycaemic indices prior to diabetes diagnosis: the Whitehall II study**D. Vistisen<sup>1</sup>, D.R. Witte<sup>1,2</sup>, A.G. Tabák<sup>2,3</sup>, E.J. Brunner<sup>2</sup>, M. Kivimäki<sup>2</sup>, K. Færch<sup>1</sup><sup>1</sup>Steno Diabetes Center A/S, Gentofte, Denmark, <sup>2</sup>Department of Epidemiology and Public Health, University College London, UK, <sup>3</sup>Department of Medicine, Semmelweis University, Budapest, Hungary.

**Background and aims:** Isolated impaired fasting glycaemia is more common in men than in women, while the opposite is true for isolated impaired glucose regulation. Moreover, women are more commonly diagnosed with type 2 diabetes on the basis of 2 h postload plasma glucose levels compared with fasting plasma glucose levels. We sought to examine sex differences in trajectories of indices of glycaemia in individuals developing type 2 diabetes.

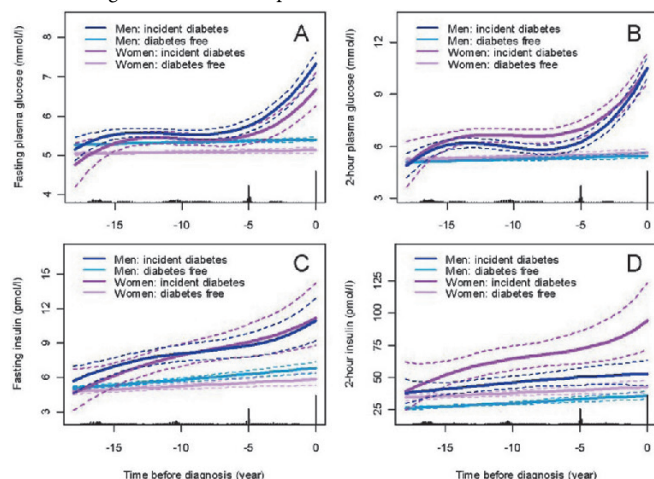

**Materials and methods:** In the prospective Whitehall II cohort of 7,364 participants, 547 men and 247 women developed diabetes during an 18-year follow-up (1991–2009). We analysed repeat data on their plasma glucose and serum insulin levels from oral glucose tolerance tests administered every 5 years, using participants who did not develop diabetes as controls ( $n=6,567$ ). Trajectories of glucose and insulin concentrations up to the date of diagnosis for incident diabetes cases and to the last date of screening for controls were

studied using growth curve mixed-effects models, with cubic term for time and adjusting for age, ethnicity and study phase.

**Results:** For fasting glucose and insulin, the shape of the curves were similar between men and women, however with higher fasting glucose levels among men over the entire follow-up (Figure 1A,  $p < 0.01$ ). In contrast, for 2-hour glucose and insulin, trajectories differed between sexes and with higher values for women, though it reached statistical significance only for 2-hour insulin (Figure 1D,  $p = 0.01$ ).

**Conclusion:** Trajectories of glucose and insulin differ between men and women before the onset of diabetes, indicating that prevention strategies for diabetes might need to be sex-specific.

**Figure 1** Trajectories of indices of glycaemia for men and women with and without diabetes during a study period of 18 years. Models were adjusted for age, ethnicity and study phase.

## 358

### Early onset type 2 diabetes and learning disability: an important and common novel clinical syndrome

A.J. Chakera, S. Irvine, S. Hammersley, M. Sheppard, UNITED research team, A.T. Hattersley;  
Peninsula College of Medicine and Dentistry, Exeter, UK.

**Background:** People with learning disability (LD) have not been recognised as having a discrete subtype of diabetes and any increased prevalence of diabetes has previously been attributed to higher rates of obesity.

**Aim:** To determine the prevalence and characteristics of patients with young-onset diabetes and learning disability.

**Methods:** Patients with LD and diabetes were identified from a population based study of patients with diabetes diagnosed <30 years. In addition we looked at the prevalence of diabetes in 1642 subjects on primary care LD registers.

**Results:** 5/45 (11.1%) patients with Type 2 diabetes (T2D) diagnosed <30 years, have learning disability requiring community support. None had known diabetes associated syndromes. This is >5-fold higher than the national prevalence of 1–2%. Patients with T2D and LD, had a lower BMI (33.5 kg/m<sup>2</sup> v 38.3 kg/m<sup>2</sup> ( $p=0.032$ )) and an earlier age at diagnosis (15.2 v 25.5 years ( $p=0.003$ )) than T2D without LD. In patients with LD the prevalence of diabetes was 99/1642 (6.0%). This is 1.5-fold higher than national prevalence in a group that has lower life expectancy and younger age distribution.

**Discussion:** We have found a strong association between young-onset Type 2 diabetes and LD in two studies ascertained by different routes. The high prevalence suggests diabetes care is an important health requirement for people with LD. The younger age of diagnosis and lower BMI suggests these patients have more severe beta-cell dysfunction than T2D in patients without LD. The association may be attributable to a previously unrecognised genetic syndrome of both diabetes and learning disability.

## 359

### Prevalence and associations of complementary and alternative medicine natural products in adults with newly diagnosed type 2 diabetes

R.N. Patel<sup>1</sup>, M.S.B. Huda<sup>1</sup>, K.F. Hunt<sup>1</sup>, K. Winkley<sup>2</sup>, K. Ismail<sup>2</sup>, S.A. Amiel<sup>1</sup>, SOUL-D Research Group;

<sup>1</sup>Diabetes Research Group, <sup>2</sup>Institute of Psychiatry, King's College London, UK.

**Background and aims:** Use of complementary and alternative medicine (CAM) in type 2 diabetes (T2DM) is high despite advances in proven conventional therapies. Its prevalence of use in the UK is unclear and its correlates with diabetes outcomes have not been investigated. We examined the utilisation of natural products (NPs), a major subcategory of CAM, in newly diagnosed T2DM and described its associations with demographic, biological and lifestyle data in a large South London cohort.

**Materials and methods:** We used data collected in the South London Diabetes (SOUL-D) cohort study which is recruiting people with newly diagnosed T2DM for the investigation of psychosocial factors in diabetes. Baseline information collected within 6 months of diagnosis of T2DM is available on 1200 participants. Data on NP use are missing for 26 patients. We subcategorised NP use into: herbs and botanicals; vitamins, minerals and oils and other. Multiple logistic regression was used to verify independent associations of NP use in individuals with T2DM, controlling for age, gender, ethnicity, biological and lifestyle factors.

**Results:** Of 1174 patients (mean duration of T2DM  $4.8 \pm 3.8$  months), 107 (9.1%) were using NPs (herbs and botanicals 30%; vitamins, minerals and oils 45%; other 13% and not specified 12%). Number of NPs consumed per person ranged from 0–6; 29% of NP users took more than one product. There were no significant differences between the NP users and the non NP users in age (mean  $56.9 \pm 10.2$  vs.  $55.4 \pm 11.6$  years), gender (male 51.4 vs. 56.2%), ethnicity (white 49.5 vs. 51.7%, African Caribbean 38.3 vs. 34.5%, Asian/other 12.2 vs. 13.8%) or occupation (professional /manager 34.3 vs. 28.9%); birth outside England (49.5 vs. 54.9%); religious identity (77.6 vs. 73.4%); diagnosis by screening (64.4 vs. 59.5%) or attendance of structured group education (12.1 vs. 17.6%). Self-employment was higher in NP users vs. non-users (27 vs. 16.8%,  $p=0.01$ ). Being a non-smoker was also significantly associated with NP use (87.4 vs. 78.8%,  $p=0.04$ ). Univariate analyses revealed better glycaemic control at diagnosis in NP users (median (IQR) HbA1c 6.7 (6.2–8.1) vs. 7.1 (6.5–8.7),  $p=0.021$ ) and correspondingly a higher HDL (1.2 (1.0–1.6) vs. 1.1 (0.96–1.4),  $p=0.016$ ). Multiple logistic regression analysis (OR [95% confidence interval],  $p$  value) found self-employment (2.14 [1.09–4.21],  $p=0.027$ ) and being a non-smoker (0.28 [0.06–0.80],  $p=0.017$ ) to be independently associated with NP use.

**Conclusion:** This is the first large prevalence study of NP users with recent onset T2DM described in a UK population. Our data show that approximately 10% of people with newly diagnosed T2DM are using NPs, significantly less than that described in other Western countries. NP use is independently associated with being self-employed and a non-smoker and may reflect a more proactive sub-group of patients with healthier behaviours.

## 360

### Optimal statin dosages and compliance: a five year retrospective cohort analysis in South Indian type 2 diabetes subjects

G. Krishnan, P. Sadasivan Pillai, A. Shankar, J. Kesavadev, S. Jothydev;  
Jothydev's Diabetes Research Center, Trivandrum, India.

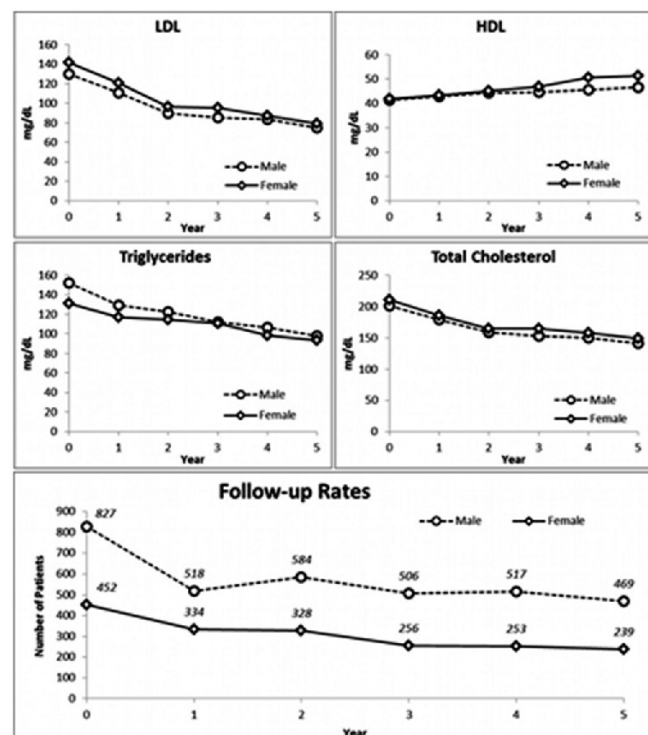

**Background and aims:** This retrospective cohort study of patients presenting in our clinic in years 2006 and 2007 was carried out to examine trends of lipid parameters, dosage requirements and compliance patterns. In our center T2DM patients with high risk are prescribed statins with a treat to target LDL goal below 70 mg/dl. Compared to other ethnicities the average statin dose requirement in Asians required to reach LDL goals may be less making it a cost effective option. One major reason for the alarming rise in cardiovascular disease epidemic in India could be attributed to irregularities in statin usage. We have earlier reported non-compliance to statin therapy in more than 60% of defaulters which is subsequent to fear of adverse effects or due to the misconception of being unnecessarily on an extra drug.

**Material and methods:** We examined de-identified records of 1279 T2DM patients above 25 years of age who were treated for dyslipidemia (65% males, mean age  $51.9 \pm 11.1$  years; 35% female, mean age  $52.6 \pm 10.8$  years). Patients were followed up via a Diabetes Tele Management System (DTMS<sup>®</sup>) by a multi-disciplinary team of doctors, dieticians, pharmacists, psychologist etc.

where in addition to the glycemic management, compliance to statins and anti-hypertensives are ensured. Follow-up rates showed sharp dropout after one or two visits to the clinic (37% males, 26% females), followed by relatively steady pattern in subsequent years. Lipid parameters of both dropouts and followed-up patients were similar initially, with average LDL levels of 135mg/dL in females and 124mg/dL in males (Fig.1).

**Results:** All patients with regular follow-up showed significant improvement in all lipid parameters, with those with 5-year follow-up showing most changes. The top three drug/dose combos and associated LDL patterns were : atorvastatin 10mg (30%; mean LDL  $74 \pm 30$  mg/dL), atorvastatin 5mg (13% subjects;  $66 \pm 22$ mg/dL) and rosuvastatin 5mg (10%;  $61 \pm 28$ mg/dL). The mean dose of atorvastatin as monotherapy among patients with LDL <100mg/dL was 14.7mg and that of rosuvastatin monotherapy was 7.2mg.

**Conclusion:** The study shows that average dosage requirements of statins in South Indian populations titrated to target lipid parameters are low, and the low compliance rate that seems to exist, pose a significant public health concern. Considering the low optimal dose of statins required in the majority of T2DM subjects to keep LDL levels at goals, this is undoubtedly a cost effective option. Widespread public health campaigns have to be promoted to maintain statin compliance among diabetes patients.

HbA1c distribution. This is illustrated in Figure 1. The median yearly HbA1c was 7.8% [95% CI: 7.7 to 7.8%]. The median HbA1c for each month was 7.8% in January, March, May and September to December and 7.7% for the rest of the months. There was no significant difference in the median HbA1c for each month ( $p=0.380$ ).

**Conclusion:** We found no variation in HbA1c across the months over the period of study. The results of the present study reaffirms that seasonal variation in HbA1c does not exist in patients with diabetes who live in tropical countries such as Singapore.

Figure 1: Monthly median HbA1c with 95% confidence intervals from 2004 to 2010

## 361

Is there seasonal variation of HbA<sub>1c</sub> in a tropical climate location such as Singapore?

D. Tay, B. Ng, L. Cho;

Changi General Hospital, Singapore.

**Background and aims:** There have been several studies examining the seasonal variability of the HbA<sub>1c</sub>. Almost all studies were done in temperate regions in both northern and southern hemispheres which showed that HbA<sub>1c</sub> varies in a sinusoidal pattern with a peak in winter and a nadir in summer. However little is known about the variations and fluctuations in HbA<sub>1c</sub> values in tropical climates such as that in Singapore in South East Asia.

**Materials and methods:** This is a retrospective study of 13886 HbA<sub>1c</sub> tests from 6646 patients who attended our diabetes service between January 2004 to March 2010. Monthly temperatures were obtained from Changi Meteorological Station. Data was analysed using SPSS version 19. One-way ANOVA test was used to compare the medians.

**Results:** There were no significant differences in monthly temperatures over the period of the study. The mean yearly temperature in Singapore was 27.8°C. Similarly there did not appear to be a seasonal variation seen in the

### 362

#### Casual blood glucose to identify diabetes as identified by HbA<sub>1c</sub>

T. Nakagami<sup>1</sup>, Y. Uchigata<sup>1</sup>, N. Yoshiike<sup>2</sup>;

<sup>1</sup>Diabetes Center, Tokyo, <sup>2</sup>Department of Health Science, Aomori, Japan.

**Background and aims:** Recently, casual blood glucose (CBG) over 200 mg/dL has been included in the 10-year risk assessment chart for death from cardiovascular disease (CVD) in Japan. CBG is measured routinely and thus could be used to identify individuals needing a diagnostic test for diabetes, as many clinicians only regard CBG  $\geq 200$  mg/dL as informative. The aim of this study was to assess whether lower values of CBG could be used for screening of diabetes in the integrated CVD screening program.

**Materials and methods:** 15,369 individuals (5,979 men) aged 20 years and older who had not been previously diagnosed with diabetes had measurements of both HbA<sub>1c</sub> and plasma CBG with information on postprandial time (0.5, 1, 2, 3, 4, 5–6, 7–8,  $>8$  hours), in the Japan National Health and Nutrition Survey conducted in 1997, 2002, and 2003. Individuals were categorized into four HbA<sub>1c</sub> groups as follows:  $<5.6$ , 5.6–5.9, 6.0–6.4 (=possible diabetes),  $\geq 6.5\%$  (=undiagnosed diabetes). The area under the receiver operating characteristic curve (AUC) for CBG corresponding to HbA<sub>1c</sub>  $\geq 6.5\%$  and  $\geq 6.0\%$  was calculated in three postprandial times:  $\leq 2$ , 3–4,  $\geq 5$  hours.

**Results:** The means (SDs) for age, CBG and HbA<sub>1c</sub> were 53 (16) years, 104 (29) mg/dL and 5.6 (0.7) %, respectively. The prevalence of HbA<sub>1c</sub>  $\geq 6.5$  and  $\geq 6.0\%$  and CBG  $\geq 200$  and  $\geq 100$  mg/dL were 5.4, 16.1, 1.4, and 46.2%, respectively. The mean CBGs increased with deteriorated with HbA<sub>1c</sub> categories in any postprandial time and decreased according to postprandial time until  $<5$  hours in any HbA<sub>1c</sub> category. The AUCs for CBG corresponding to HbA<sub>1c</sub>  $\geq 6.5\%$  in postprandial time  $\leq 2$ , 3–4,  $\geq 5$  hours were 87.2 (95% CI: 84.7–90.1), 86.1 (83.4–88.7) and 81.6 (78.6–84.6). The respective values corresponding to HbA<sub>1c</sub>  $\geq 6.0\%$  were 73.1 (71.0–75.3), 74.8 (72.9–76.6) and 70.6 (68.5–72.6). These were higher in postprandial time  $<5$  hours than  $\geq 5$  hours ( $p<0.05$ ). This finding was not influenced by the condition of CVD risk factors: age, hypertension, hyperlipidemia and smoking status. The table shows the performance of different CBGs corresponding to HbA<sub>1c</sub>  $\geq 6.5$  or  $\geq 6.0\%$  according to postprandial time. When CBG  $\geq 200$  or  $\geq 100$  mg/dL were used for the screening of diabetes, the positive predictive value (PPV) and the specificity increased and the sensitivity decreased according to postprandial time course. The optimal cut-off of CBG maximizing sensitivity plus specificity for HbA<sub>1c</sub>  $\geq 6.5\%$  decreased with postprandial time course: 130, 122, and 108 mg/dL. The respective values for HbA<sub>1c</sub>  $\geq 6.0\%$  were: 117, 111, and 98 mg/dL. In the data analysis of postprandial time  $\geq 5$  hours, the CBGs that provided identical prevalence of HbA<sub>1c</sub>  $\geq 6.5\%$  ( $=4.7\%$ ) and  $\geq 6.0\%$  ( $=13.7\%$ ) were 124 mg/dL and 109 mg/dL, respectively.

**Conclusion:** CBG is a useful screening test for diabetes defined by HbA<sub>1c</sub>. The lowered cut-off of CBG (around 110–130 mg/dL) could be efficiently used for the screening of diabetes in the integrated CVD screening program.

Performance of different CBGs corresponding to HbA<sub>1c</sub> over 6.5% or 6.0% by postprandial time

casual blood glucose (mg/dL)	post-prandial time (hours)	HbA <sub>1c</sub> over 6.5% (undiagnosed DM)				HbA <sub>1c</sub> over 6.0% (possible DM)

#### A cross-sectional study for assessment and validation of the estimated formula of 2-hour post-challenge glucose level composing fasting glucose level and HbA<sub>1c</sub>

Y. Kondo<sup>1</sup>, N. Harada<sup>1</sup>, A. Hamasaki<sup>1</sup>, D. Nastesuka<sup>1</sup>, S. Yamane<sup>1</sup>, A. Muraoka<sup>1</sup>, T. Sozu<sup>2</sup>, N. Inagaki<sup>1</sup>;

<sup>1</sup>Kyoto University Graduate School of Medicine, <sup>2</sup>Biostatistics, Kyoto University School of Public Health, Japan.

**Background and aims:** Postprandial hyperglycemia begins prior to Type 2 diabetes mellitus (T2DM). Since, it is a high risk factor not only for development of T2DM but also for development of macrovascular disease, its detection and early intervention are critical for preventing pre-diabetes and reducing diabetic complications. Oral glucose tolerance test (OGTT) is an appropriate method for estimating postprandial hyperglycemia. So far, combination of fasting plasma glucose levels (FPG) and HbA<sub>1c</sub> (without OGTT) was used for DM or impaired glucose tolerance (IGT) screening. However, the calculation of estimated formula of 2-hour post-challenge plasma glucose level (2hPG) during OGTT and validation of the accuracy of the formula were not assessed. So we designed a hospital-based cross-sectional study to assess and validate the estimated formula of 2hPG composing FPG and HbA<sub>1c</sub>, and then verified whether the subjects should undergo OGTT or not.

**Materials and methods:** 380 Japanese participants undergoing 75g OGTT were recruited. Gender, age, body mass index (BMI) and HbA<sub>1c</sub> were checked. OGTT was performed and PG and serum insulin (IRI) levels were measured at 0, 30, 60, 90, and 120 min after oral administration of 75g glucose. We separated subjects into two groups randomly: Test group (n=190) for stepwise multiple linear regression analysis, and validation group (n=190) for validation between measured 2hPG (m2hPG) obtained from OGTT and estimated 2hPG (e2hPG) calculated from estimated formula. We also analyzed the sensitivity (Sn), specificity (Sp), and the receiver-operating characteristic (ROC) curve in validation group to assess the optimal cut-off values for detecting DM and IGT. Data were analyzed using JMP Statistical Software (ver. 9).

**Results:** According to the WHO criteria, the subjects were classified into the four groups: normal glucose tolerance (NGT) 32.9%, impaired fasting glucose (IFG) 2.4%, IGT 28.1%, DM 36.6%. Mean age was 54.5 $\pm$ 15.6 (mean $\pm$ SD) years and mean BMI was 23.4 $\pm$ 4.8 kg/m<sup>2</sup>. High linear correlations between m2hPG and FPG and between m2hPG and HbA<sub>1c</sub> were demonstrated, with  $r=0.75$  and  $0.70$ , respectively, which were regarded as strongest predictors of m2hPG. Multiple linear regression analysis was performed in the test group;  $e2hPG = 1.67 \times FPG \text{ (mmol/L)} + 1.63 \times HbA_{1c} - 10.1$  (adjusted  $R^2 = 0.60$ ,  $P<0.0001$ ). In the validation group, when the cut-off value was based on the diagnosis of DM (11.1 mmol/L) and IGT (7.8 mmol/L), the equation had 80% Sn and 95% Sp for detecting DM, and 86% Sn and 39% Sp for detecting IGT, respectively. ROC curve showed the optimal cut-off values of e2hPG at 10.8 mmol/L with 85% Sn and 94% Sp for detecting DM, and at 7.5 mmol/L with 92% Sn and 38% Sp for detecting IGT.

**Conclusion:** For detecting non-IGT and DM, high Sn and Sp are needed for cut-off value, respectively. The present study demonstrated that our formula is useful to judge the necessity of OGTT, that is, the values of e2hPG  $< 7.8$  mmol/L or  $11.1$  mmol/L  $< e2hPG$  could be regarded as non-IGT and DM, respectively.

### 364

#### Fasting plasma glucose (FPG), HbA<sub>1c</sub> and OGTT in screening for type 2 diabetes: the diabetes mellitus and vascular health initiative (DMVhi) study

M. Sinnott<sup>1</sup>, B. Kinsley<sup>2</sup>, T. O'Grady<sup>1</sup>, C. Walsh<sup>3</sup>, P. Gaffney<sup>4</sup>, G. Boran<sup>4</sup>, J.J. Nolan<sup>5</sup>, B. Carr<sup>6</sup>;

<sup>1</sup>Wellness, Vhi Healthcare, Dublin, <sup>2</sup>Diabetes, Mater Misericordiae University Hospital, Dublin, <sup>3</sup>Statistics, Trinity College, Dublin, <sup>4</sup>Clinical Chemistry Laboratory, Tallaght Hospital, Dublin, Ireland, <sup>5</sup>Chief Executive, Steno Diabetes Center, Copenhagen, Denmark, <sup>6</sup>Medical, Vhi Healthcare, Dublin, Ireland.

**Background and aims:** Early diagnosis and treatment improves outcomes in T2DM. In pre-diabetes (preDM) lifestyle modification prevents or delays progression to T2DM. The DMVhi Study was undertaken by Ireland's largest health insurer to assess prevalence of T2DM and preDM and to investigate efficient approaches to population screening. The aim of this abstract is to

compare a combination of FPG, HbA<sub>1c</sub> and OGTT with FPG and OGTT as a screening method for T2DM and preDM.

**Materials and methods:** Policy holders (45–75 years, non DM) in two major urban areas were invited for screening. To date over 24,000 individuals have been screened. This abstract describes data for a sub group of 2,460 individuals where each participant had an HbA<sub>1c</sub> and FPG measured, plus OGTT if FPG  $\geq 5.6 \leq 6.9$  mmol/L or repeat FPG if  $\geq 7.0$  mmol/L.

**Results:** FPG and OGTT screening gave a DM rate = 1.3%, preDM = 5.8%, normal = 92.9%. OGTT rate = 9.8%. FPG and HbA<sub>1c</sub> screening gave a DM rate = 1.3%, preDM = 36%, normal = 62.7%. Adding OGTT to HbA<sub>1c</sub> and FPG screening in the preDM group with both IFG and HbA<sub>1c</sub> of 5.7–6.4% identified 10 extra cases of T2DM. This screening method results in a DM rate of 1.8%, preDM = 35.5%, normal = 62.7% with an OGTT rate of 6.2%.

**Conclusion:** This data may suggest that screening using FPG and HbA<sub>1c</sub> with OGTT performed in those with both FPG and HbA<sub>1c</sub> in the preDM range, increases T2DM detection rate by 38% compared to screening with either FPG and OGTT or FPG and HbA<sub>1c</sub>. Using this method the OGTT rate decreases by 37% as compared to screening with FPG and OGTT.

## 365

### Screening for diabetes and pre-diabetes with combined use of FPG and quantitative postprandial urine glucose in Chinese high-risk population: a community-based study

J. He<sup>1</sup>, Z. Sun<sup>1</sup>, T. Wu<sup>2</sup>, Z. Xie<sup>1</sup>, Y. Lu<sup>3</sup>, C. Lei<sup>1</sup>, J. Han<sup>1</sup>, Y. Zhou<sup>1</sup>;

<sup>1</sup>Endocrinology, Institute of Diabetes, Zhongda Hospital, Nanjing, China,

<sup>2</sup>Discipline of Medicine, University of Adelaide, Australia, <sup>3</sup>Hi-Tech Research Institute, Nanjing University of Technology, China.

**Background and aims:** Fasting plasma glucose (FPG) has not been sensitive enough for diabetes screening, while measurements of oral glucose tolerance test (OGTT) and HbA<sub>1c</sub>, although reliable, are time-consuming and resource-dependent, appearing less practical in large-scale screening, especially in low-income regions. The study was designed to evaluate the utility of the combination of FPG and quantitative postprandial urine glucose (PUG) in diabetes screening among Chinese high-risk population.

**Materials and methods:** Subjects with high risks but no previous diabetes history were recruited from 8 Chinese community medical centers from September 2010 to September 2011 for the measurements of FPG, 75 g-OGTT, HbA<sub>1c</sub> and 2h-PUG after 75 g oral glucose intake. The ROC curve was used to evaluate the performance of PUG in diabetes screening, from which an optimal threshold of PUG was estimated. Combined use of FPG and PUG in diabetes and pre-diabetes screening was evaluated against FPG alone.

**Results:** 909 out of 1035 subjects completed the study. The levels of 2h-PUG in response to 75g oral glucose positively correlated to FPG, 2h-PG, and HbA<sub>1c</sub>, respectively ( $P < 0.001$  for each). A threshold of 2h-PUG at 135 mg/dL was estimated to detect a 2h-PG  $\geq 11.1$  mmol/L, with a sensitivity of 76.2% and a specificity of 89.4%. In contrast to FPG, combined use of FPG ( $\geq 5.6$  mmol/L),  $< 7.0$  mmol/L, and PUG ( $\geq 135$  mg/dL) had a comparable capacity to detect glycemic dysregulation, with a sensitivity of 84.9% and specificity of 66.3% to identify a 2h-PG  $\geq 11.1$  mmol/L, and a sensitivity of 68.6% to predict postprandial hyperglycemia (2h-PG  $\geq 7.8$  mmol/L). Both sensitivity was higher than applying FPG test alone in screening ( $P < 0.0000$  for each comparison).

**Conclusion:** The combined use of FPG and PUG shows a good performance in diabetes and pre-diabetes screening, although its specificity for diabetes diagnosis is relatively low. The measurements of FPG and PUG may not replace the diagnostic value of OGTT, but represents a promising method for diabetes and pre-diabetes screening among high-risk population.

### Post glucose-load hypoglycaemia is not associated with increased incidence of diabetes after three years. The DEPLAN study

S. Liatis, C. Stathi, A. Tsiakou, D. Perrea, N. Katsilambros, K. Makrilakis; First Department of Internal Medicine, Diabetes Center, Athens, University Medical School, Laiko Hospital, Greece.

**Background and aims:** It has been reported that postprandial (reactive) hypoglycaemia may be related to future development of diabetes. Aim of the present analysis was to investigate the relationship between hypoglycaemia

that develops two hours after an oral glucose tolerance test (OGTT) and incidence of diabetes or impaired glucose tolerance (IGT) after 3 years.

**Materials and methods:** The study participants were healthy individuals who underwent an OGTT during a screening procedure for participation in the Greek arm of a European, community-based, type 2 diabetes prevention programme by lifestyle modification (DEPLAN). The OGTT was repeated 3 years later. Post-load hypoglycaemia was defined as a plasma glucose value  $\leq 70$  mg/dl at two hours. IGT was defined as a plasma glucose value 140–199 mg/dl at two hours post-load.

**Results:** The analysis was performed in 229 individuals (116 males, mean age: 53.67 [52.37–54.98] years, mean BMI: 29.43 [28.76–30.10] Kg/m<sup>2</sup>), with normal baseline glucose tolerance (NGT). At baseline, 37 individuals (16.16%) had 2hr post-load hypoglycaemia. Three-year incidence of diabetes and/or IGT was lower in those with 2hr post-load hypoglycaemic plasma glucose levels at baseline (3/37 [8.11%] vs. 43/189 [22.75%], OR: 0.309 [0.090–1.056],  $p=0.06$ ). After adjustment for age, gender, family history of diabetes, BMI, and fasting plasma glucose at baseline, 2hr post-load hypoglycaemia was not associated with increased risk for diabetes and/or IGT development after three years (OR: 0.49 [0.14–1.80]).

**Conclusion:** Individuals who exhibit hypoglycaemia two hours after a 75g oral glucose load do not seem to be at increased risk for diabetes development in the short-term (up to three years). Analyses in larger cohorts for longer periods of time are needed, in order to expand the investigation in sub-populations and draw more solid conclusions.

### Utility of HbA<sub>1c</sub> as a screening tool for diagnosis of diabetes and prediabetes in Indian population

R. Rajput;

PGIMS, Rohtak, India.

**Background and aims:** The aim of study was to evaluate the performance of HbA<sub>1c</sub> and FPG tests as a mass screening tool for diabetes and pre-diabetes as defined by standard oral glucose tolerance test (OGTT).

**Materials and methods:** Data from 1008 participants of age 20–75 years enrolled in population based cross sectional study from urban areas of Rohtak city, Haryana were analysed. 2-hr.75 gm OGTT was used to diagnose diabetes and pre-diabetes. Performance of HbA<sub>1c</sub> and FPG was evaluated against the results of OGTT by using receiver operating characteristic curve (ROC) analysis.

**Results:** The prevalence of pre-diabetes and newly diagnosed diabetes was found 20.6% and 12.5% respectively. For subjects with newly diagnosed diabetes, the area under the ROC curve was 0.957 for A1C and 0.942 for FCG ( $P$  value 0.11), whereas for pre-diabetes, these values were 0.831 for HbA<sub>1c</sub> and 0.807 for FPG ( $p$  value 0.205). At the optimal HbA<sub>1c</sub> cutoff points of 5.4% for pre-diabetes and of 6.2% for newly diagnosed diabetes, sensitivities (specificities) were 79.02%(79.31%) and 92.24%(90.52%) respectively. Similarly FPG optimal cut off points of  $\geq 97$  mg% for pre-diabetes and  $\geq 119$  mg% for diabetes were found to have max. sensitivities (specificities) of 93.17(63.32) and 93.54(89.64) respectively.

**Conclusion:** As a screening tool for newly diagnosed diabetes and pre-diabetes, the HbA<sub>1c</sub> measurement performed not inferior than FPG in this study population.

## 368

### Glycated HbA<sub>1c</sub> for diagnosing diabetes in 1329 Chinese subjects over 50 years old: a community-based cross-sectional study

S. Lin, X. Li, L. Hu, S. He, Z. Ren, X. Tang, Y. Qiu, J. Xu, P. Mu, L. Zeng; Department of Endocrinology, The 3rd Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.

**Background and aims:** Recently, substantial evidence shows that glycated haemoglobin A<sub>1c</sub> (HbA<sub>1c</sub>) may be a useful tool for screening for and diagnosis of diabetes. However, little is known about using HbA<sub>1c</sub> to screen for diabetes and/or impaired fasting glucose (IFG) in Chinese subjects over 50 years old. This study aims to evaluate HbA<sub>1c</sub> in diagnosing diabetes and identify the optimal HbA<sub>1c</sub> cut-off to be used in Chinese subjects aged over 50 years in a community-based setting.

**Materials and methods:** A community-based cross-sectional epidemiological survey was conducted during Oct 2010 to Jan 2011 in Shipai community

of Guangzhou city, Guangdong province, South China. A total of 1494 subjects aged over 50 years were investigated. All participants completed a uniform questionnaire containing questions about the histories of current and previous illness and medical treatment. Fasting blood samples were obtained to measure plasma glucose and HbA<sub>1c</sub>. Plasma glucose was measured by glucose oxidase method and HbA<sub>1c</sub> was measured by using high performance liquid chromatography (D-10, BIO-RAD, America, reference range was 4.0–6.0%). The glycaemic thresholds for diagnosis of diabetes and IFG were based on the 1999 World Health Organization criteria. Diabetes is defined as fasting plasma glucose (FPG) of at least 7.0 mmol/L. 161 subjects (10.8%) had previously diagnosed with diabetes and 4 with missing data were excluded and data from 1329 subjects (50–96 years old) were analysed. Pearson correlation analysis was done to investigate the association of HbA<sub>1c</sub> with FPG; Receiver Operating Characteristics curve (ROC) were plotted to assess the sensitivity and specificity of HbA<sub>1c</sub> in identifying participants as having undiagnosed diabetes or IFG.

**Results:** 1329 subjects had average age 62 years (interquartile range: 55–67 years), mean FPG 5.2 mmol/L (SD 1.3 mmol/L), mean HbA<sub>1c</sub> 5.8% (SD 0.75%), and were 60% female. Among them, 54 subjects (4.1%) had diabetes, 88 subjects (6.6%) had IFG, 10.7% had hyperglycemia (diabetes plus IFG). HbA<sub>1c</sub> was significantly positively correlated with FPG (correlation coefficient was 0.784,  $P < 0.001$ ). According to the receiver operating characteristics curve, the area under the curve for HbA<sub>1c</sub> in diagnosing diabetes and hyperglycemia (diabetes plus IFG) were 0.945 (95% CI 0.910–0.981) and 0.849 (95% CI 0.810–0.889) respectively. An HbA<sub>1c</sub> threshold of 6.5% yielded the highest combination of sensitivity (83.3%) and specificity (95.8%) for diagnosing diabetes (with a highest Youden's index of 0.791). At an optimal cut-off point of  $\geq 6.1\%$ , the sensitivity was 71.8% and specificity 83.1% for diagnosing hyperglycemia (with a highest Youden's index of 0.549).

**Conclusion:** An HbA<sub>1c</sub> threshold of 6.5% was highly specific and have a good sensitivity for diagnosing diabetes in Chinese adults aged over 50 years in community-based setting. This optimal HbA<sub>1c</sub> threshold may be suitable as a diagnostic criterion for diabetes in elderly Chinese people when fasting plasma glucose and oral glucose tolerance tests are not available.

## PS 013 Risk scores for type 2 diabetes and disease complications

369

### Comparison of the Leicester risk assessment score, FINDRISC and SCOUT DS\* for diabetes screening in an at-risk Greek population

P. Lathouris<sup>1</sup>, K. Tzemos<sup>2</sup>, J.D. Maynard<sup>3</sup>, N. Tentolouris<sup>4</sup>;

<sup>1</sup>Central Diabetes Center, Greece National Social Insurance Institute, Athens, Greece, <sup>2</sup>KTIC, Athens, Greece, <sup>3</sup>R&D, VeraLight, Inc., Albuquerque, USA,

<sup>4</sup>Internal Medicine, Laiko General Hospital, Athens, Greece.

**Background and aims:** An important part of diabetes prevention is screening of at risk subjects to detect disease development at an early stage. Methods that are noninvasive, non-fasting, provide immediate results and simple to administer can facilitate ascertainment of at risk individuals. We examined the accuracy of Leicester Diabetes Risk Assessment score (LDRA), the concise Finnish Diabetes Risk Score (FINDRISC) and the skin fluorescence based SCOUT DS diabetes score for detecting increasing levels of dysglycemia as defined by HbA<sub>1c</sub>.

**Materials and methods:** Subjects at risk for type 2 diabetes but without an existing diagnosis of diabetes were recruited at the diabetes centers for the LAIKO General Hospital and Greece National Social Insurance Institute in Athens, Greece. ~200 subjects were recruited at each clinical site. Subject participation consisted of a single, non-fasting visit that lasted less than 30 minutes. The clinic staff measured the subject's height, weight and waist circumference. Skin fluorescence was measured on the underside of the left forearm with the SCOUT DS device and it calculated a diabetes score. A finger prick was done to measure RCG (OneTouch Ultra) and HbA<sub>1c</sub> (DCA Vantage). A health history questionnaire was completed by each subject to characterize cohort demographics. We used concise FINDRISC score (does not require physical activity and consumption of fruits, vegetables and berries data) because we did not collect information on consumption of fruits, vegetables and berries. A point of care HbA<sub>1c</sub> measurement was used as the reference and dysglycemia states of  $\geq 6.0\%$  and  $\geq 6.5\%$  were defined.

**Results:** 398 of 409 subjects had complete data for analysis with means and 95% confidence intervals for A1c, age, BMI, and waist of  $5.7 \pm 1.2\%$ ,  $52.3 \pm 29.4$  yrs,  $27.3 \pm 9.8$  kg/m<sup>2</sup> and  $90 \pm 26.8$  cm. 51% were male and the cohort was 99.5% Caucasian. Prevalence of HbA<sub>1c</sub>  $\geq 6.0\%$  and  $\geq 6.5\%$  were 34% and 12%, respectively. The receiver operator characteristic curves for detection of A1c  $\geq 6.0\%$  are shown in Figure 1. SCOUT DS had significantly greater area under the curve (AUC) for both levels of dysglycemia relative to the LDRA and FINDRISC. For detection of HbA<sub>1c</sub>  $\geq 6.0\%$ , the SCOUT DS, LDRA and FINDRISC AUCs were 84.0%, 74.9% and 73.6%, respectively. For detection of HbA<sub>1c</sub>  $\geq 6.5\%$ , the SCOUT DS, LDRA and FINDRISC AUCs were 90.4%, 78.6% and 79.4%, respectively (ROCs not shown).

**Conclusion:** All methods were able to detect HbA<sub>1c</sub>-defined dysglycemia and have the benefits of being simple, noninvasive, non-fasting and providing immediate results at the point of service. At the respective screening thresholds, SCOUT DS detected 20% and 30% more cases of HbA<sub>1c</sub>  $> 6.0\%$  compared to FINDRISC and LDRA with comparable specificity. In this study, SCOUT DS had superior detection capability relative to the questionnaire-based LDRA and concise FINDRISC scores.

## 370

**Risk scores for diabetes and impaired glycaemia in the Middle East and North Africa**

L.N. Handlos<sup>1</sup>, D.R. Witte<sup>1</sup>, T.P. Almdal<sup>1</sup>, L.B. Nielsen<sup>2</sup>, S.E. Badawi<sup>3</sup>, A.R.A. Sheikh<sup>4</sup>, M. Belhadj<sup>5</sup>, D. Nadi<sup>6</sup>, S. Zinai<sup>7</sup>, D. Vistisen<sup>1</sup>; <sup>1</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>2</sup>Novo Nordisk, Bagsvaerd, Denmark, <sup>3</sup>UAE Ministry of Health, Dubai, United Arab Emirates, <sup>4</sup>King Abdul Aziz University Hospital, Jeddah, Saudi Arabia, <sup>5</sup>EHU, Oran, Algeria, <sup>6</sup>Algerian Ministry of Health, Algiers, Algeria, <sup>7</sup>Novo Nordisk, Algiers, Algeria.

**Background and aims:** The world's highest prevalence of diabetes is found in the Middle East and North Africa (MENA) region. We aimed to develop a simple and non-invasive risk score for diabetes and impaired glycaemia in the MENA region. Furthermore, we aimed to derive national risk scores for Algeria, Saudi Arabia (KSA) and the United Arab Emirates (UAE).

**Materials and methods:** Between November 2010 and December 2011, 7,216 individuals between 30 and 75 years of age were screened in Algeria, KSA and UAE. Screening was based on opportunity sampling and consisted of a self-administered questionnaire and a clinical examination including measurement of HbA<sub>1c</sub>. One regional and three national risk scores were developed in a stepwise approach. First univariate associations between diabetes or impaired glycaemia (HbA<sub>1c</sub> ≥ 6.0%) and each of the potential risk factors were assessed separately. Secondly, risk factors significant at a 10% level in the univariate analyses were included in a multiple logistic regression using stepwise backward elimination. A p value of <5% was considered significant. To ensure a parsimonious model, risk factors which at the same time added less than 1% to the area under the receiver operating characteristics curve (AUC) and less than 5% to the relative integrated discrimination improvement were successively removed. The risk factors in the final model were each assigned a score by multiplying the regression coefficients by 10 and rounded off to the nearest integer. Each participant was assigned a summed risk score calculated by adding the individual scores of the risk factors in the model. A cut-point value on the risk score corresponding to a sensitivity as close to 75% as possible was chosen. The AUC of the MENA and the national risk scores were compared in data from each country using DeLong's method.

**Results:** After exclusion of those with known diabetes and missing data, the analyses included 6,588 (91%) out of the 7,216 individuals who were screened. An average 54.8% were men, mean age was 44.3 years, 10.0% had impaired glycaemia (HbA<sub>1c</sub> ≥ 6.0% and < 6.5%) and 7.8% had undetected diabetes (HbA<sub>1c</sub> ≥ 6.5%). The final risk scores included different combinations of age, BMI, family history of diabetes, gender, gestational diabetes, ownership of computer, self-assessed health and ethnicity (Asian or other). AUC for the MENA score was between 0.69 (95% CI: 0.66–0.72) and 0.70 (0.67–0.73). For sensitivities around 75%, specificities varied from 52% (50%–54%) to 53% (51%–55%) according to country. Generally the MENA and the national risk scores performed equally well in the three samples. In KSA, the national risk score performed significantly better (p<5%) than the MENA risk score, but the actual difference in AUC was very small, and the discrepancy in performance mainly existed at sensitivities below 70%.

**Conclusion:** A regional score for diabetes and impaired glycaemia in the MENA region was developed. The MENA score performed as well as the nationally derived risk scores from Algeria, KSA and UAE.

## 371

**Screening questionnaires are useful in identifying undiagnosed HbA<sub>1c</sub> diagnosed diabetes in a Caucasian population**

B.A. Knight, B. Shields, G. Baker, A. Hattersley, A. Jones; Peninsula Clinical Research Facility, Peninsular Medical School, Exeter, UK.

**Background and aims:** Type 2 diabetes is a common metabolic disorder which may go undiagnosed and untreated for many years, leading to increased morbidity and mortality. Early detection and instigation of treatment may reduce these risks and the World Health Organisation (WHO) now recommends the use of an HbA<sub>1c</sub> value of 48mmol/mol (6.5%) as the cut off value for the diagnosis of diabetes. The Leicester Risk Assessment (LRA) Score and the Cambridge Risk Assessment (CRA) Score have been developed as simple non invasive screening tools which utilise routinely available clinical characteristics to identify those at risk of undiagnosed type 2 diabetes. They were developed using OGTT (rather than HbA<sub>1c</sub>) to define diabetes. We aimed to assess the ability of these two risk scores to detect diabetes de-

fined by HbA<sub>1c</sub> in a predominantly Caucasian population without known diabetes.

**Materials and methods:** Baseline clinical data for both scoring systems (including age, sex, ethnicity, family history, BMI, waist circumference, known hypertension, current medication and smoking history) was available on 2130 participants aged 40–75 years of age without known diabetes from the Exeter Ten Thousand (EXTEND) research study. We calculated the LRA and CRA scores for all participants. We determined area under receiver operating characteristic curve (ROC AUC) for detection of diabetes (defined by HbA<sub>1c</sub> ≥ 48mmol/mol (6.5%)) for each risk score. We determined sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and likelihood ratios for each risk score in detecting diabetes using the suggested LRA score cut off for diabetes of ≥14 and the equivalent CRA score of ≥0.127.

**Results:** Baseline characteristics of participants were (mean (SD)): age 57.0 (9.4) years, BMI 26.7 (4.4), 99% Caucasian and 36% Male. Prevalence of undiagnosed HbA<sub>1c</sub> defined diabetes was 3.1%. AUC ROC for undiagnosed diabetes was 0.80 (perfect test = 1.0) for the LRA score and 0.83 for the CRA score. Using their suggested cut offs for type 2 diabetes gave 83.6% sensitivity and 58.5% specificity (LRA score), and 83.3% sensitivity and 58.1% specificity (CRA score). PPV and NPV for both scores were identical (6.1% and 99.1% respectively). Positive and negative likelihood ratios were 2.0 and 0.28 (LRA score) and 2.16 and 0.21 (CRA score).

**Conclusion:** Both the LRA and CRA scores are potentially useful screening tools with moderately high sensitivities and negative predictive values but poor specificity. A positive result from these screening tools doubles the probability that a patient has undiagnosed diabetes from 3 to 6%. A negative result reduces the probability of undiagnosed diabetes to <0.9%. Given the poor specificity and availability of an inexpensive diagnostic test (HbA<sub>1c</sub>) selective testing other than on the basis of age may not be justified. Further assessment is needed of the utility and cost effectiveness of these scoring systems.

## 372

**Prediction of incident diabetes mellitus in nondiabetic Asian subjects: a 4-year retrospective, longitudinal study**

M. Seo, W.-S. Jeon, S. Park, E. Rhee, C. Park, K. Oh, S. Park, S. Kim, W.-Y. Lee; Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

**Background and aims:** Prediction rules for Type 2 diabetes (T2DM) have been developed. But we lack consensus for the most effective approach in non-diabetic Asian. Our objective was to assess T2DM prediction models in non-diabetic Asian.

**Materials and methods:** A total of 5596 Koreans without diabetes who underwent consecutive comprehensive health check-ups annually for 5yr were enrolled. There were 332 cases of new T2DM, and regression models were used to predict new T2DM, starting with characteristics known to the subject (personal model, ie, age, sex, and body mass index (BMI)), adding simple clinical measurements that included metabolic syndrome traits (simple clinical model), and, finally, assessing complex clinical models that included the homeostasis model assessment-insulin resistance (HOMA-IR), fasting serum insulin level, and diagnosis of non-alcoholic fatty liver disease by ultrasonography. Discrimination was assessed with area under the receiver operating characteristic curves (AROCs).

**Results:** The personal model variables statistically significant predictors of T2DM (AROC, 0.672). In the simple clinical model, the point estimate of AROC was 0.801. Complex clinical models showed no further improvement in model discriminations (AROC 0.804) and were not superior to the simple clinical model.

**Conclusion:** We found that age, sex, obesity, and metabolic traits effectively predict T2DM risk in Asian and were used to develop a simple T2DM prediction algorithm to estimate risk of new T2DM during a 5 year follow up interval.

**Comparison of prediction of T2DM according to Clinical variables**

Model (variables)	AROC
Personal (age, sex, BMI)	0.672
Simple (personal added hypertension, low level of high-density cholesterol, elevated triglyceride levels, increased waist circumference and impaired fasting glucose)	0.801
Complex (Simple added HOMA-IR, fasting serum insulin and NAFLD)	0.804

## 373

**Characteristics and treatment of patients with type 2 diabetes and renal impairment in the UK**H.T. Smith<sup>1</sup>, S. Davé<sup>2</sup>, I. Eriksson<sup>2</sup>, S. Lawson<sup>1</sup>, A. Martin<sup>1</sup>, A. Lawton<sup>1</sup>, J. Cid-Ruzafa<sup>2</sup>, A. Maguire<sup>2</sup>;<sup>1</sup>GlaxoSmithKline, London, <sup>2</sup>United BioSource Corporation, London, UK.

**Background and aims:** Among patients with type 2 diabetes (T2DM) 30–50% have evidence of renal impairment. Options for management of hyperglycaemia in patients with T2DM and renal impairment are limited; higher levels of a drug or its active metabolites can increase the risk of adverse events and dose adjustments to improve tolerability are common in drugs cleared by renal excretion, potentially reducing efficacy. A number of commonly used drugs for T2DM are not recommended in patients with end stage renal disease. The objective of the study was to estimate the prevalence and severity of renal impairment in patients with T2DM in the UK and to describe differences between patients with and without renal impairment in terms of characteristics, treatment, comorbidities, and healthcare resource utilisation. This abstract describes the characteristics and treatment of patients with T2DM and renal impairment in the UK.

**Materials and methods:** This is a cross-sectional study. The study population comprised patients with T2DM, diagnosed or treated on or prior to the cross-sectional study date (1/7/2010). The medical history was observed for the entire record prior to/on the cross sectional date. Patients with T2DM were identified by diagnosis codes and prescription history. Stage (1 to 5) specific chronic kidney disease (CKD) Read codes were used to define renal impairment (or absence, stage 0) within the T2DM population; for patients without a Read code, eGFR was estimated and used to classify degree of renal impairment.

**Results:** 150,084 patients with T2DM were identified, a CKD stage could be identified for 127,370 (85%). Mean age was 66.9 years and 55.6% of the population were male. 47% of the T2DM patients in the study were defined as having CKD, the majority having moderate disease (stage 2–3). Patients with CKD were older than those without and age increased with CKD stage. Based on BMI 51% of patients were classed as obese ( $\geq 30$  kg/m<sup>2</sup>), the proportion was slightly higher in patients with CKD (54%). Only 54% of patients achieved target HbA1c of  $\leq 7\%$ . Prescribing varied according to CKD stage. Prescription of metformin fell with more advanced CKD and insulin prescribing was higher in the more severe CKD stages. Prevalence of several diabetes related comorbidities including coronary heart disease, congestive heart failure, peripheral vascular disease and retinopathy/blindness was higher in the CKD patient population, increasing with CKD severity.

Table 1: Patient characteristics and diabetes treatment

	No CKD						All CKD patients	All patients
	Stage 0	Stage 1	Stage 2	Stage 3	Stage 4	Stage 5		
N (%)	68,089 (53)	3,069 (2)	15,803 (12)	36,304 (29)	3,332 (3)	773 (1)	59,281 (47)	127,370 (100)
Age, years; mean (SD)	63.4 (12.63)	60.8 (13.89)	66.8 (12.43)	72.7 (10.43)	77.7 (9.01)	73.6 (10.62)	70.8 (11.75)	66.9 (12.77)
% Male	54.8	53.9	60.5	55.6	48.2	59.5	56.5	55.6
BMI, kg/m <sup>2</sup> ; mean (SD)	30.6 (6.21)	29.6 (6.68)	30.9 (6.44)	31.7 (6.45)	31.9 (6.79)	31.3 (6.27)	31.4 (6.50)	30.9 (6.36)
HbA1c (% at target = 7%)	53.7	47.0	49.8	56.0	52.0	61.2	53.7	53.7
<b>Treatment at 1/7/2010 (% on therapy)</b>								
Metformin	60.7	65.7	63.3	55.1	18.2	8.4	55.1	58.1

Peripheral vascular disease	10.0	13.0	14.9	18.1	26.4	29.8	17.6	13.5
Hypertension	31.3	32.5	33.9	33.5	33.3	38.9	33.6	32.4
Other cardiovascular disorders~	24.6	25.7	30.8	35.7	46.6	48.3	34.6	29.3
Retinopathy/blindness	21.1	24.7	26.7	27.5	39.3	43.9	28.0	24.3
Neuropathy	4.5	5.6	6.8	7.5	12.4	16.0	7.6	5.9

\* Acute renal failure, renal failure and other renal disorder

~ Revascularization, acute coronary syndrome, cerebrovascular disease, myocardial infarction, hypercholesterolemia, amputation

**Conclusion:** Almost half of the T2DM patient population had some degree of CKD and management of HbA1c was poor; approximately half of patients achieving HbA1c treatment goals. The CKD population exhibited higher rates of comorbidities. Limited approved treatment options are available for these patients. Despite contraindications, metformin use was predominant in the CKD population and there was an increased use of insulin compared to the broader T2DM population.

Supported by: GlaxoSmithKline

## 374

**Prevalence of chronic kidney disease in type 2 diabetes - results from a nationwide survey in Germany**L.F. Merker<sup>1</sup>, B. Gallwitz<sup>2</sup>, B. Waldeck<sup>3</sup>, K. Schoene<sup>3</sup>;<sup>1</sup>Diabetes- und Nierenzentrum Dormagen, <sup>2</sup>Medizinische Klinik 4, Eberhard Karls Universität Tübingen, <sup>3</sup>Boehringer Ingelheim Pharma GmbH & Co KG, Ingelheim, Germany.

**Background and aims:** Chronic kidney disease in type 2 diabetes (T2D) is common, however, in primary care settings renal disease is frequently under-recognized and the true prevalence remains vague. In Germany a systematic prospective nationwide database on the prevalence of chronic kidney disease (CKD) in type 2 diabetes is lacking.

**Materials and methods:** To evaluate the frequency of CKD in T2D we performed a large, pre-defined and prospective nationwide survey. 2541 individuals with type 2 diabetes were recruited from 245 primary care sites. Renal screening habits prior to this survey were assessed by questionnaire. On site urinalysis was evaluated by dipstick. Central renal lab included serum creatinine, and urine albumin-creatinine-ratio (UACR); eGFR (ml/min/1.73m<sup>2</sup>) was estimated by MDRD formula. The study was conducted according to GCP standards and approved by German ethics committees. All statistical analyses were descriptive. The study was performed between February and July 2011.

**Results:** Data were available for 2531 individuals (1345 male, 1186 female). Baseline characteristics of the overall population were: Age 69.5 yrs., BMI 30.5 kg/m<sup>2</sup>, HbA1c 6.7 %, diabetes duration 8.3 years. 83 % had hypertension, 98 % received antihypertensive treatments. 1) Assessment of renal function: Prior to this study screening for renal function was conducted by serum creatinine measurement in 97%, by eGFR estimation in 51% and by Cockcroft-Gault calculation in 9%. In the study moderate renal impairment (RI) (CKD 3, eGFR 30–60 ml/min/1.73m<sup>2</sup>) was present in 27.7 %. 43.7 % of the affected had CKD diagnosis prior to this study, 55.3% were newly diagnosed. Severe RI (CKD 4, eGFR 15–30 ml/min/1.73m<sup>2</sup>) was present in 1.4 % with the magnitude previously diagnosed (91.4 % vs. 8.6% newly diagnosed). 2) Assessment of renal damage: Prior to this study screening for albuminuria was conducted in 54% by dipstick and in 7% by laboratory assessment. In the study elevated UACR (>30mg/g creatinine) was detected in 22.2 %, with micro- and macroalbuminuria being present in 17.6 % and 4.5% respectively. When considering signs of renal function decline and damage, 40.8% were affected by CKD: Micro- and macroalbuminuria associated with CKD was present in 6% and 2.5%. eGFR <60 ml/min/1.73m<sup>2</sup> without albuminuria was found in 18.7 % and albuminuria with eGFR >60 ml/min/1.73m<sup>2</sup> in 13.6%.

**Conclusion:** Based on these results, CKD is a common condition in T2D in Germany with 4 out of 10 patients being affected. However, in more than half of all patients being identified with moderate renal impairment this condition was previously not diagnosed. Assessing renal function using both eGFR and screening for albuminuria is most appropriate to detect renal disease in T2D. This should be mandatory particularly in elderly patients to detect renal impairment, which is necessary e.g. for dose adjustments of medication or referral to nephrologists.

### Glomerular filtration rate-dependent association of serum uric acid with metabolic syndrome and hepatic fat content in Chinese community population

M.-F. Xia<sup>1</sup>, H.-D. Lin<sup>1</sup>, X.-M. Li<sup>1</sup>, H.-M. Yan<sup>1</sup>, H. Bian<sup>1</sup>, W.-Y. He<sup>2</sup>, X. Gao<sup>1</sup>;  
<sup>1</sup>Endocrinology, <sup>2</sup>Ultrasonography, Zhongshan Hospital, Shanghai, China.

**Background and aims:** Mounting evidence has demonstrated that hyperuricaemia was involved in the development of metabolic syndrome (MS), type 2 diabetes and non-alcoholic fatty liver disease (NAFLD). All these conditions are thought to be partly mediated by the pro-oxidant effect of uric acid. However, uric acid is also a special molecule with a dual role both as a pro- and as an anti-oxidant under different physicochemical circumstance, and some recent studies indicated a different contribution of hyperuricaemia for the occurrence of metabolic disorders between subjects with diet and lifestyle-induced uric acid over-production and those with uric acid retention due to impaired renal excretion function. The aim of this study was to detect the association of serum uric acid level with MS and NAFLD in a middle-aged and elderly population with normal and impaired renal excretion function, respectively.

**Materials and methods:** A cross-sectional study was performed in a community population comprising 1141 subjects enrolled consecutively to Shanghai Changfeng Study in one year. Participants with hepatitis B or C, excessive alcohol intake and other hepatic disease or use of hepatic protectant or hypouricemic agents were excluded. A standard interview, anthropometric, laboratory measurement and hepatic fat content quantification by a newly-established were performed for each participant.

**Results:** ① Serum uric acid was significantly associated with hepatic fat content ( $r=0.193$ ,  $P<0.001$ ) and higher in subjects with metabolic syndrome than those without metabolic syndrome ( $P<0.001$ ) by univariate correlation analysis and independent-sample t-test, especially in subjects with normal renal excretion function ( $\text{GFR} \geq 90 \text{ ml/min/1.73m}^2$ ) ( $r=0.255$ ,  $P<0.001$ ). ② Logistic regression analysis showed that in subjects with  $\text{GFR} \geq 90 \text{ ml/min/1.73m}^2$ , elevation of serum uric acid was independently associated with the occurrence of metabolic syndrome ( $\text{OR}[95\% \text{CI}]: 1.004[1.002-1.007]$ ) (Table 1) and NAFLD ( $\text{OR}[95\% \text{CI}]: 1.005[1.002-1.007]$ ), but not in those with renal insufficiency ( $\text{GFR} < 90 \text{ ml/min/1.73m}^2$ ). ③ By using new ultrasound quantitative method for hepatic fat content, we found that uric acid level was independently associated with hepatic fat content ( $P=0.003$ ) only in participants with normal renal function, but not in subjects with  $\text{GFR} < 90 \text{ ml/min/1.73m}^2$  (Table 1).

**Conclusion:** Hyperuricaemia was independently associated with MS and NAFLD in people with normal renal excretion function, but in patients with renal excretion insufficiency, the meaning of hyperuricaemia on metabolic disorders should be explained with caution.

Multivariate regression analysis showing factors independently associated with MS/hepatic fat content					
Metabolic syndrome			Hepatic fat content		
Independent variables	OR (95% CI)	P value	Independent variables	Standardized $\beta$	P value
GFR $\geq 90 \text{ ml/min/1.73m}^2$			GFR $\geq 90 \text{ ml/min/1.73m}^2$		
age	1.027(1.007-1.048)	0.008	BMI	0.348	$<0.001$
BMI	1.404(1.311-1.504)	$<0.001$	Age	-0.121	0.001
Uric acid	1.004(1.002-1.007)	0.002	Triglycerides	0.113	0.002
GFR $< 90 \text{ ml/min/1.73m}^2$			GFR $< 90 \text{ ml/min/1.73m}^2$		
BMI	1.506(1.377-1.648)	$<0.001$	Uric acid	0.110	0.003
age	1.029(1.007-1.052)	0.011	BMI	0.397	$<0.001$
-	-	-	Triglycerides	0.140	0.001
-	-	-	Age	-0.096	0.027

The values included for analysis of MS risk factors were age, sex, BMI, smoking status, alcohol drinking, GFR and Uric acid, and all the above parameters, liver enzymes and MS components were included for analysis of independent factors associated with hepatic fat content.

### Relationships of visit-to-visit variability and time-to-effect in systolic blood pressure to the risks of nephropathy and retinopathy in type 2 diabetes

T. Takao<sup>1</sup>, T. Ide<sup>1</sup>, H. Yanagisawa<sup>2</sup>, M. Kikuchi<sup>1</sup>, S. Kawazu<sup>1</sup>, Y. Matsuyama<sup>3</sup>;

<sup>1</sup>Division of Diabetes and Metabolism, The Institute for Adult Diseases, Asahi Life Foundation, Tokyo, <sup>2</sup>Department of Public Health and Environmental Medicine, The Jikei University School of Medicine, Tokyo, <sup>3</sup>Department of Biostatistics School of Public Health, University of Tokyo, Japan.

**Background and aims:** Visit-to-visit variability in BP has been found to independently add to the mean BP in predicting the risk of diabetic nephropathy (DNp), but not retinopathy (DR), in type 1 diabetes. Lack of a BP legacy effect on cardiovascular events has been reported in type 2 diabetes (T2D). This study aimed to determine whether systolic BP (SBP) variability can predict progression of DNp and DR, independently of the mean SBP, in patients with T2D, and to evaluate the time-to-effect relationship between SBP control and the risks of DNp and DR.

**Materials and methods:** A total of 670 (553 men, 117 women) patients with T2D who first visited our hospital from 1995 to 1996 with less than one year of discontinuation were followed up through 2010. Their mean age, duration of diabetes, BMI, BP, HbA1c, creatinine (Cr) and nonHDLcholesterol (nonHDL-C) at baseline were 55.8 years, 5.7 years, 23.4 kg/m<sup>2</sup>, 133.6/77.8 mmHg, 7.6%, 0.80 mg/dl and 160.6 mg/dl, respectively. Insulin therapy and antihypertensive drugs at baseline were administered to 86 and 158 patients, respectively. The total number of SBP measurements was 51,615. Progression of DNp was defined as doubling of Cr, and DR was onset of mild-moderate non-proliferative DR. 536 of 670 had no DR at first visit. 665 of 670 and 531 of 536 had at least two SBP determinations for each endpoint. SD or CV was used as a measure of SBP variability.

**Results:** By the end of follow-up, DNp had progressed in 31 patients and DR in 106. The SD or CV of SBP was a significant predictor of DNp, but not DR, independently of mean SBP (Table). SBP, analyzed as a time-dependent covariate (last observation carried forward, LOCF), was non-significant for DNp but significant for DR, after adjusting for the baseline covariates and mean of BMI, HbA1c and nonHDL-C. Adjusted HR for the annual mean SBP before progression of DNp and DR was obtained using the moving-mean method. HR of the mean SBP for DNp became significant during the 6-year period and gradually increased over the 15-year period before progression of DNp. HR of the mean SBP for DR was highest during the first year, then decreased and became non-significant during the 6-year period, and plateaued and decreased slowly during the 12- to over 15-year period before progression of DR.

**Conclusion:** Visit-to-visit SBP variability is a significant predictor of progression of DNp, but not DR, in patients with T2D, independently of the mean SBP. DNp progression was significantly associated with the mean SBP of more than 6 years earlier. In contrast, DR was less than 5 years earlier. These findings suggest a SBP legacy effect on progression of DNp, but not DR. SBP should be managed with emphasis on early and stable control to prevent DNp, and continuous lowering to prevent DR.

Multivariate Cox proportional hazard models for the progression of nephropathy and retinopathy

#### Glycaemic threshold for diabetes specific retinopathy among individuals from Saudi Arabia, Algeria and Portugal are not different from other populations

T.P. Almdal<sup>1</sup>, L.N. Handlos<sup>1</sup>, E. Juul<sup>1</sup>, M. Amtoft<sup>1</sup>, D. Vistisen<sup>1</sup>, L.B. Nielsen<sup>2</sup>, S.E. Badawi<sup>3</sup>, A.R.A. Sheikh<sup>4</sup>, M. Belhadj<sup>5</sup>, D. Nadir<sup>6</sup>, S. Zinai<sup>7</sup>, J. Raposo<sup>8</sup>, M. Kozarzewski<sup>9</sup>, H. Lund-Andersen<sup>1</sup>, D.R. Witte<sup>1</sup>;

<sup>1</sup>Steno Diabetes Center, Gentofte, Denmark, <sup>2</sup>Novo Nordisk, Bagsvaerd, Denmark, <sup>3</sup>UAE Ministry of Health, Dubai, United Arab Emirates, <sup>4</sup>King Abdul Aziz University Hospital, Jeddah, Saudi Arabia, <sup>5</sup>EHU, Oran, Algeria, <sup>6</sup>Algerian Ministry of Health, Algiers, Algeria, <sup>7</sup>Novo Nordisk Algeria, Algiers, Algeria, <sup>8</sup>APDP, Lisbon, Portugal, <sup>9</sup>Novo Nordisk, Lisbon, Portugal.

**Background and aims:** Previous studies from the US, Australia and Asia included in the Detect 2 study reports a glycemic threshold for diabetes specific retinopathy of 6.3 - 6.7%. There are only one such study from the Middle East and none from Europe. The aim of the present study was to investigate the glycemic threshold of retinopathy in populations from Saudi Arabia, Algeria and Portugal.

**Materials and methods:** Individuals without any previous history of diabetes was offered screening for diabetes in three countries; Saudi Arabia, Algeria and Portugal in an opportunistic design. All Individuals were offered determination of HbA<sub>1c</sub> (DCA 2000 technique). Among those with HbA<sub>1c</sub> <6.0% every 10<sup>th</sup> individual (n= 168) were offered retinal examination while all individuals (n= 582) with HbA<sub>1c</sub> ≥ 6.0% were offered retinal examination. The retinal examination consisted of 2 photos of the retina of each eye. The photos were assessed according to a modified ETDRS scale standard. Results are reported as presence of any retinopathy given abnormalities in a least one eye or presence of diabetes specific retinopathy in at least one eye.

**Results:** 789 individuals were screened; 299 in Saudi Arabia, 294 in Algeria and 196 in Portugal. Mean age varied from 44.6 years in Saudi Arabia to 60.8 years in Portugal and the proportion of men was between 46.1% and 54.0% in Portugal and Saudi Arabia, respectively. Mean HbA<sub>1c</sub> level was 6.6% in Saudi Arabia, 7.1% Algeria and 6.3% in Portugal, and BMI ranged from 29.4 kg/m<sup>2</sup> in Portugal to 31.6 kg/m<sup>2</sup> in Saudi Arabia. The prevalence of any retinopathy and diabetes specific retinopathy weighed according to probability of selection for retinopathy screening was 1.65% and 0.77%, respectively, in the sample from all three countries. The standardized risk for having retinopathy (for a 50-year old man) was 1.1% (0.6; 1.8) in Saudi Arabia, 1.9% (1.3; 3.0) in Algeria and 2.7% (1.7; 4.2) in Portugal.

**Conclusion:** The present study confirms that the glycemic threshold for diabetes specific retinopathy is HbA<sub>1c</sub> = 6.0 - 6.5%. Among persons with HbA<sub>1c</sub> ≥ 7% the prevalence is above 6% which also corroborates well with previous results.

Figure 1. Prevalence of any retinopathy and diabetes specific retinopathy according to HbA<sub>1c</sub> group with 95% confidence intervals

### Islet GPR55 is coupled to increased insulin secretion and decreased apoptosis

S. Song<sup>1</sup>, B. Liu<sup>1</sup>, D. Baker<sup>2</sup>, G.C. Huang<sup>1</sup>, S.A. Amiel<sup>1</sup>, A.J. King<sup>1</sup>, J.E. Bowe<sup>1</sup>, P.M. Jones<sup>1</sup>, S.J. Persaud<sup>1</sup>;

<sup>1</sup>Diabetes Research Group, DNS Division, King's College London, <sup>2</sup>Blizard Institute, Barts and the London School of Medicine and Dentistry, London, UK.

**Background and aims:** We have recently reported that CB1 and CB2 cannabinoid receptors are expressed by islet  $\beta$ -cells where they regulate insulin secretion. A novel cannabinoid receptor, GPR55, is also activated by endocannabinoids, but it has some atypical features such as being activated by the CB1 antagonist AM251 and showing agonist activity to the lipid lysophosphatidylinositol (LPI). The physiological role of this receptor in islets has not been established so the current study investigated GPR55 expression and function in mouse and human islets.

**Materials and methods:** RT-PCR and Western blotting were used to detect GPR55 mRNA and protein expression, and insulin secretion from mouse and human islets was quantified by radioimmunoassay. Intraperitoneal glucose tolerance tests (IPGTTs) were performed on GPR55 knockout (KO) mice and their wildtype littermates. Apoptosis was induced by exposure of mouse islets to mixed cytokines for 20 hours and caspase-3/7 activities were quantified by a luminescent assay.

**Results:** Amplicons of the appropriate sizes were obtained using cDNAs from mouse and human islets with GPR55 primers, and an immunoreactive protein of the expected size was detected by Western blotting of mouse and human islet protein extracts. Activation of GPR55 using a pharmacological agonist (10  $\mu$ M O-1602) caused a reversible stimulation of insulin secretion from perfused mouse and human islets at 2mM glucose (peak stimulation, mouse:  $243 \pm 38\%$ ; human:  $450 \pm 200\%$ ,  $n=3-4$ ,  $P<0.05$ ). O-1602 significantly ( $P<0.05$ ) potentiated glucose-induced insulin secretion from mouse islets (peak stimulation above 20mM glucose plateau:  $220 \pm 44\%$ ,  $n=4$ ), and also from human islets (peak stimulation:  $190 \pm 29\%$ ,  $n=4$ ). In addition, the putative endogenous GPR55 ligand (5  $\mu$ M LPI) significantly elevated basal insulin secretion from mouse and human islets (peak stimulation, mouse:  $208 \pm 12\%$ ; human:  $1200 \pm 200\%$ ,  $n=3-4$ ,  $P<0.05$ ). Administration of LPI during the second phase of glucose-induced insulin secretion significantly potentiated insulin secretion from mouse and human islets (peak stimulation above 20mM glucose plateau, mouse:  $190 \pm 27\%$ ; human:  $747 \pm 180\%$ ,  $n=4$ ,  $P<0.05$ ). In static incubation secretion experiments a novel GPR55 agonist, CID1792197, also stimulated insulin secretion, as did AM251, a CB1 antagonist known to activate GPR55 in some cell types (2mM glucose:  $0.28 \pm 0.05$  ng/islet/h; + 10  $\mu$ M CID1792197:  $0.66 \pm 0.18$ ; + 10  $\mu$ M AM251:  $0.63 \pm 0.17$ ,  $n=6-8$ ,  $P<0.05$ ). IPGTTs of normal weight GPR55 KO mice indicated that there was a small impairment of glucose handling following GPR55 deletion (peak excursion at  $t=15$ , WT mice:  $11.4 \pm 0.9$  mM glucose; KO mice:  $14.1 \pm 1.7$  mM glucose,  $n=3-4$ ). Islets isolated from GPR55 KO mice also showed higher basal levels of apoptosis (luminescence units: WT mice:  $68,495 \pm 1,074$ ; KO mice:  $114,128 \pm 3,068$ ,  $n=16$ ,  $P<0.01$ ) and in the presence of cytokines (WT mice:  $253,047 \pm 7,125$ ; KO mice:  $283,403 \pm 6,678$ ,  $n=16$ ,  $P<0.01$ ).

**Conclusion:** GPR55 is expressed by islets and its activation with a range of pharmacological agonists stimulates insulin secretion from mouse and human islets *in vitro*. Global knockout of GPR55 was associated with a small decrease in glucose tolerance and enhanced islet apoptosis. These data are consistent with GPR55 playing an important role in glucose homeostasis through increased insulin secretion and maintenance of  $\beta$ -cell mass.

### CB<sub>1</sub> cannabinoid receptor ligands exhibit CB<sub>1</sub>-dependent and independent effects in CB<sub>1</sub> receptor-deficient mouse islets

C. Li<sup>1</sup>, J.E. Bowe<sup>2</sup>, D. Baker<sup>3</sup>, P.M. Jones<sup>2</sup>, S.J. Persaud<sup>2</sup>;

<sup>1</sup>Dasman Diabetes Institute, Kuwait City, Kuwait, <sup>2</sup>King's College London, UK, <sup>3</sup>Queen Mary University, London, UK.

**Background and aims:** We have previously demonstrated that islet CB<sub>1</sub> receptors are coupled to decreased cyclic AMP (cAMP) and increased intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ), and their activation with apparently selective pharmacological agonists stimulates insulin secretion from isolated mouse and human islets. However, both CB<sub>1</sub> agonists and antagonists have been reported to exert effects independently of their interaction with CB<sub>1</sub> receptors, so this study investigated the function of islets isolated from wildtype (WT) and CB<sub>1</sub> knockout (KO) mice and the effects of pharmacological cannabinoids on these islets.

**Materials and methods:** Islets were isolated from global CB<sub>1</sub> receptor-deficient mice and wildtype littermates by collagenase digestion of the pancreas. Cyclic AMP and  $[\text{Ca}^{2+}]_i$  levels were measured by ELISA and microfluorimetry, respectively. The dynamics and reversibility of insulin secretion were determined by radioimmunoassay following perfusion of isolated mouse islets *in vitro*.

**Results:** Islets isolated from KO and WT mice were indistinguishable in terms of yield and morphology. CB<sub>1</sub>-deficient islets exhibited enhanced insulin secretion in response to 20mM glucose ( $1,370 \pm 178\%$  vs  $699 \pm 76\%$  basal,  $n=4$ ,  $P<0.01$ ), which may be attributable, at least in part, to their higher insulin content (WT:  $30.8$  ng/islet; KO:  $50.5$  ng/islet). Administration of 10  $\mu$ M ACEA, a CB<sub>1</sub> agonist, significantly inhibited forskolin-induced cAMP production in WT islets ( $65 \pm 6\%$  of 10  $\mu$ M forskolin response,  $n=4$ ,  $P<0.05$ ), but had no effect in KO islets ( $91 \pm 16\%$  of 10  $\mu$ M forskolin response,  $n=5-7$ ,  $P>0.2$ ). Exposure of dispersed WT islet cells to 1  $\mu$ M ACEA led to increased  $[\text{Ca}^{2+}]_i$  ( $42 \pm 13\%$  of maximum tolbutamide response,  $n=3$ ), although subsequent treatment with 10  $\mu$ M ACEA elicited no response, most likely due to receptor desensitisation. However, 10  $\mu$ M ACEA unexpectedly caused a significant ( $P<0.01$ ) increase in  $[\text{Ca}^{2+}]_i$  in KO islets ( $39 \pm 6\%$  of maximum tolbutamide response,  $n=6$ ). ACEA activates TRPV<sub>1</sub> channels in other cells types and their activation is coupled to increased  $[\text{Ca}^{2+}]_i$  in  $\beta$ -cells, so the ACEA-mediated  $[\text{Ca}^{2+}]_i$  increase in CB<sub>1</sub>-deficient islet cells may occur via TRPV<sub>1</sub> activation. The competitive CB<sub>1</sub> antagonist AM251 significantly ( $P<0.05$ ) increased  $[\text{Ca}^{2+}]_i$  in WT islets ( $71 \pm 19\%$  of maximum tolbutamide response,  $n=4$ ), perhaps through activation of the novel cannabinoid GPR55 receptors, which we have identified in islets. As expected, 10  $\mu$ M ACEA reversibly potentiated insulin secretion from WT islets (from  $22.3 \pm 2.7$  pg/islet/min to  $35.1 \pm 2.2$ ,  $n=4$ ,  $P<0.01$ ), but it also exerted similar stimulatory effects in islets from KO mice (from  $33.6 \pm 3.2$  pg/islet/min to  $52.7 \pm 9.6$ ,  $n=4$ ,  $P<0.05$ ).

**Conclusion:** The use of islets isolated from CB<sub>1</sub> receptor knockout mice has demonstrated that ACEA and AM251 exhibit both CB<sub>1</sub> receptor-dependent and independent effects on  $[\text{Ca}^{2+}]_i$  and insulin secretion, suggesting that caution should be exercised when using these ligands to define the roles of CB<sub>1</sub> receptors in islet function.

### Chronic activation of cannabinoid receptors modifies gene expression, glucagon content, but not insulin secretion from mouse islets *in vitro*

A. Vilches-Flores<sup>1,2</sup>, S.J. Persaud<sup>1</sup>;

<sup>1</sup>Diabetes Research Group, King's College London, UK, <sup>2</sup>Universidad Nacional Autonoma de Mexico, Mexico City, Mexico.

**Background and aims:** We have previously demonstrated that short term activation of cannabinoid receptors stimulates insulin secretion from mouse and human islets. There is evidence that the endocannabinoid system (ECS) is overactive in type 2 diabetes, which may impact on impaired glucose homeostasis. Islets produce endocannabinoids, but little is known about whether the local ECS may play a role in islet dysfunction. The aim of the current study, therefore, was to investigate the effect of chronic exposure to pharmacological cannabinoid receptors agonists on gene expression and secretory function of isolated mouse islets.

**Materials and methods:** Mouse islets were maintained in culture with 100nM ACEA (CB<sub>1</sub>R agonist) or 100nM JWH015 (CB<sub>2</sub>R agonist), for 48 hours and 7 days. Messenger RNAs encoding preproinsulin, preproglucagon, cannabinoid receptors (CB<sub>1</sub>R and CB<sub>2</sub>R), biosynthetic (NAPE-PLD, DAG-

L) and degrading (FAAH, MGL) enzymes were quantified by real-time PCR. Radioimmunoassay was used to determine dynamic insulin secretion from perfused islets, and islet insulin and glucagon contents.

**Results:** NAPE-PLD and FAAH mRNAs are relatively highly expressed in islets ( $0.35 \pm 0.002\%$  and  $2.1 \pm 0.1\%$  of preproinsulin mRNA levels, respectively), with much lower levels of CB1R, CB2R, DAG-L and MGL mRNAs (all  $<0.1\%$  of FAAH levels), suggesting that the synthesis and degradation of endogenous CB1R agonist is important in islet function. Islets treated with  $100\text{ nM}$  of the CB2R agonist JWH015 for 48 hours showed significant reductions in mRNAs encoding CB2R, DAG-L and NAPE-PLD (by  $54 \pm 16\%$ ,  $59 \pm 18\%$  and  $46 \pm 21\%$ , respectively,  $n=4$ ,  $P<0.01$ ), suggesting a negative feedback on receptor and biosynthetic enzyme expression. Exposure to JWH015 for 48 hours and 7 days led to significant reductions in preproglucagon mRNA (by  $70 \pm 10\%$ ,  $P<0.01$ ,  $n=3$  and  $36 \pm 5\%$ ,  $P<0.05$ ,  $n=4$ ), preproinsulin mRNA at 48 hours (by  $30 \pm 8\%$ ,  $P<0.05$ ,  $n=4$ ), and FAAH and MGL at 7 days (by  $42 \pm 5\%$  and  $37 \pm 2\%$ ,  $P<0.05$ ,  $n=4$ ). Glucagon content was also significantly reduced ( $45 \pm 15\%$ , and  $40 \pm 18\%$ ,  $P<0.05$ ,  $n=4$ ) following JWH015 exposure for 48 hours or 7 days and although there was an increase in insulin content this was not statistically significant ( $41.6 \pm 12.5$  ng/islet vs  $29.6 \pm 8.9$  in control,  $n=6$   $P>0.1$ ). These observations suggest that  $\alpha$ -cells could be more sensitive than  $\beta$ -cells to chronic activation of CB2 receptors. The CB1R agonist ACEA increased FAAH mRNA expression at 48 hours (by  $50 \pm 20\%$ ,  $n=4$ ,  $P<0.05$ ) and at 7 days ( $36 \pm 8\%$ ,  $n=4$ ,  $P<0.05$ ) of exposure, consistent with increased turnover of the endogenous CB1R agonist anandamide. Perfusion experiments showed that acute exposure to ACEA and JWH015 induced reversible increases in insulin secretion at  $3\text{ mM}$  glucose at 48 hours (by  $52 \pm 26\%$  and  $48 \pm 24\%$ ,  $n=3$ ,  $P<0.05$ ), and 7 days (by  $25 \pm 12\%$  and  $65 \pm 21\%$ ,  $n=3$ ,  $P<0.05$ ), both in control islets and in those treated chronically with cannabinoids. The  $16\text{ mM}$  glucose-induced insulin secretion was not modified in islets by chronic exposure to ACEA or JWH015.

**Conclusion:** These data indicate that chronic exposure of isolated mouse islets to a CB2R agonist has direct effects on gene expression of ECS components, on glucagon mRNA and protein content, but there are no deleterious effects on insulin content or insulin secretion. Chronic CB1R activation is associated with increased expression of the anandamide-degrading enzyme FAAH, but also does not disrupt glucose-induced insulin secretion.

### Expression and function of CCL5 and the receptors GPR75, CCR1, CCR3 and CCR5 in islets of Langerhans

Z. Hassan, B. Liu, S. Amisten, G.C. Huang, S.A. Amiel, P.M. Jones, S.J. Persaud;

Diabetes Research Group, King's College London, UK.

**Background and aims:** Chemokine ligand 5 (CCL5) is a 68 amino acid protein that belongs to the CC-chemokine subfamily, and stimulates the migration of monocytes and T cells to damaged and infected sites following an inflammatory insult. This is mediated via CCL5 activation of the CCR family of chemokine receptors. However, it is now apparent that CCL5 also stimulates the recently de-orphanised G-protein coupled receptor 75 (GPR75), which shows little sequence homology with the conventional chemokine receptors. CCL5 increases intracellular  $\text{Ca}^{2+}$  ( $[\text{Ca}^{2+}]_i$ ) in GPR75 transfected CHO cells and it also acts via GPR75 to inhibit neuronal cell death. The current study investigated the expression of CCL5, GPR75, CCR1, CCR3 and CCR5 in mouse and human islets of Langerhans, the effects of CCL5 on insulin secretion and the potentially protective effects of CCL5 activation of GPR75 on  $\beta$ -cell survival.

**Materials and methods:** CCL5, CCR1, CCR3, CCR5 and GPR75 expression and cellular localisation in mouse and human islets were examined by quantitative RT-PCR, western blotting and immunohistochemistry (IHC). Insulin secretion was quantified by radioimmunoassay after perfusion of isolated mouse islets. Apoptosis was induced by exposure of MIN6  $\beta$ -cells or mouse islets to mixed cytokines (IFN $\gamma$ , TNF $\alpha$ , IL-1 $\beta$ ) or cis-diaminedichloroplatinum (cis-Pt) for 20 hours and caspase-3/7 activities were quantified by the luminescent CaspaseGlo assay. MIN6  $\beta$ -cell proliferation was quantified by measuring the rate of BrdU incorporation into cellular DNA.

**Results:** Quantitative RT-PCR indicated that islets expressed CCL5 and GPR75 mRNAs (CCL5:  $2.7 \pm 0.6\%$  and  $0.4 \pm 0.16\%$  of GAPDH mRNA expression, mouse and human islets respectively; GPR75:  $5.4 \pm 1.2\%$  and  $0.29 \pm 0.11\%$ , respectively,  $n=3$ ). CCR1, CCR3 and CCR5 mRNAs were also detected in mouse islets, but at significantly lower levels than quantified for GPR75, while CCR5 mRNA was not detected in human islets and only trace amounts of

CCR1 and CCR3 mRNAs were present. IHC revealed widespread GPR75 immunoreactivity in mouse and human islets, consistent with a  $\beta$ -cell localisation and a  $59\text{ kDa}$  immunoreactive protein was detected by western blotting. Islets also expressed the GPR75 ligand CCL5. Exposure of isolated mouse and human islets to exogenous CCL5 potentiated glucose-stimulated insulin secretion (mouse,  $20\text{ mM}$  glucose plateau:  $263 \pm 48\%$  basal;  $+20\text{ nM}$  CCL5:  $540 \pm 103\%$ ,  $n=4$ ,  $P<0.01$ ; human,  $20\text{ mM}$  glucose plateau:  $306 \pm 32\%$  basal;  $+10\text{ nM}$  CCL5:  $601 \pm 92\%$ ,  $n=4$ ,  $P<0.01$ ). In MIN6  $\beta$ -cells CCL5 significantly increased proliferation (BrdU incorporation, absence of CCL5:  $1.28 \pm 0.04$  absorbance units,  $+25\text{ nM}$  CCL5:  $1.71 \pm 0.10$ ,  $n=7$ ,  $P<0.01$ ) and reduced cytokine-induced caspase 3/7 activities (cytokines:  $1,073,086 \pm 24,422$ ;  $+25\text{ nM}$  CCL5:  $1,001,520 \pm 17,051$ ,  $n=8$ ,  $P<0.05$ ). CCL5 also significantly reduced apoptosis in mouse islets (cytokines:  $171,263 \pm 37,605$ ;  $+2.5\text{ nM}$  CCL5:  $76,395 \pm 8,573$ ; cis-Pt:  $78,210 \pm 8,370$ ;  $+2.5\text{ nM}$  CCL5:  $50,723 \pm 7,066$ ,  $n=8$ ,  $P<0.05$ ).

**Conclusion:** CCL5 is expressed by mouse and human islets where it may exert auto/paracrine effects via the most abundant CCL5 receptor, GPR75, to potentiate insulin secretion, stimulate  $\beta$ -cell proliferation and inhibit  $\beta$ -cell apoptosis. These data suggest that GPR75-selective agonists may be potential therapies for the treatment of Type 2 diabetes mellitus.

## 382

### Regulation of $[\text{Ca}^{2+}]_i$ and insulin secretion by activation of FFAR1 in murine beta cells

G. Drews<sup>1</sup>, D. Cornejo<sup>1</sup>, A. Edalat<sup>1</sup>, G. Schulz-Raffelt<sup>2</sup>, M. Düfer<sup>1</sup>,

P. Krippeit-Drews<sup>1</sup>, E. Christiansen<sup>3</sup>, H.U. Häring<sup>2</sup>, T. Ulven<sup>3</sup>, S. Ullrich<sup>2</sup>;

<sup>1</sup>Pharmazeutisches Institut, Tübingen, Germany, <sup>2</sup>Department of Internal Medicine IV, University Hospital Tübingen, Germany, <sup>3</sup>University of Southern Denmark, Odense, Denmark.

**Background and aims:** Free fatty acids (FFAs) exert stimulating or inhibiting effects on beta cell function depending on the signalling pathways that are activated. The insulinotropic effect of FFAs is mediated by the stimulation of free fatty acid receptor 1 (FFAR1/GPR40), a Gq-coupled receptor which is proposed to activate phospholipase C. With respect to a possible insulinotropic action we aimed to investigate the effects of specific activation of FFAR1 by small receptor agonists and conjugated linoleic acids (CLAs) on glucose-induced insulin secretion (GIIS) and to analyse the changes of cytosolic  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) in primary mouse beta cells.

**Materials and methods:** In isolated islets and islet cells from C57BL/6 mice and FFAR1 knock-out mice insulin secretion was measured after static incubations by radioimmunoassay and  $[\text{Ca}^{2+}]_i$  by the fura-2 technique, respectively. FFAR1 was activated by a synthetic, small molecular agonist, TUG-469, and CLAs which do not stimulate FFAR2 and FFAR3 in expression systems.

**Results:** TUG-469 ( $10\text{ }\mu\text{M}$ ) augmented GIIS in wild type (from  $2.9 \pm 0.4$  to  $4.5 \pm 0.5\%$  of insulin content;  $n=11$ ;  $p \leq 0.05$ ) but not in FFAR1 knock-out mouse islets ( $2.1 \pm 0.3$  vs.  $2.5 \pm 0.3\%$ ;  $n=12$ , n.s.). Concomitantly, TUG-469 ( $100\text{ nM}$  and  $10\text{ }\mu\text{M}$ ) augmented  $[\text{Ca}^{2+}]_i$  at a stimulatory glucose concentration of  $15\text{ mM}$  ( $100\text{ nM}$ : from  $215 \pm 9\text{ nM}$  to  $284 \pm 17\text{ nM}$ ,  $n=11$ ,  $P \leq 0.01$ ;  $10\text{ }\mu\text{M}$ : from  $280 \pm 31\text{ nM}$  to  $355 \pm 27\text{ nM}$ ,  $n=17$ ,  $P \leq 0.05$ ). This effect was not owing to  $\text{Ca}^{2+}$  release from intracellular stores since the glucose- and TUG-induced increase in  $[\text{Ca}^{2+}]_i$  was abolished by the L-type  $\text{Ca}^{2+}$  channel blocker nifedipine ( $10\text{ }\mu\text{M}$ ) ( $n=11-18$ ). The SERCA inhibitor thapsigargin did not prevent the TUG-469-induced increase in  $[\text{Ca}^{2+}]_i$  ( $100\text{ nM}$  TUG: from  $194 \pm 17\text{ nM}$  to  $261 \pm 24\text{ nM}$ ,  $n=13$ ,  $P \leq 0.001$ ). Activation of muscarinic receptors by carbachol ( $10\text{ }\mu\text{M}$ ) still transiently increased  $[\text{Ca}^{2+}]_i$  from  $84 \pm 5\text{ nM}$  to  $196 \pm 20\text{ nM}$  after treatment of the cells with TUG-469 ( $n=18$ ,  $P \leq 0.001$ ). The effect of TUG-469 on  $[\text{Ca}^{2+}]_i$  was absent in beta cells of FFAR1 knock-out mice ( $n=20$ ). Similar to TUG-469, CLAs ( $100\text{ }\mu\text{M}$ ), widely used as dietary supplements, stimulated insulin secretion through FFAR1. The increase in  $[\text{Ca}^{2+}]_i$  induced by both isomers ( $100\text{ }\mu\text{M}$ ), CLA9c,11t (from  $265 \pm 21\text{ nM}$  to  $386 \pm 24\text{ nM}$ ,  $n=31$ ,  $P \leq 0.001$ ) and CLA10t,12c (from  $239 \pm 14\text{ nM}$  to  $340 \pm 20\text{ nM}$ ,  $n=32$ ,  $P \leq 0.001$ ), was, however, only partly reduced in  $\beta$ -cells of FFAR1 knock-out mice ( $n=31$  and  $n=46$ ,  $P \leq 0.05$  FFAR1 knock-out vs. wild type mice).

**Conclusion:** The specific activation of FFAR1 augments GIIS which makes FFAR1 attractive as a target for oral antidiabetic drugs. The insulinotropic effect of TUG-469 is solely due to FFAR1 activation while CLAs evidently exert additional effects on beta cell stimulus-secretion coupling. The data further suggest that FFAR1-induced IP $_3$ -dependent  $\text{Ca}^{2+}$ -release does not explain TUG-469 and CLA-induced changes in  $[\text{Ca}^{2+}]_i$ .

## 383

**Purinoreceptor-mediated feedback in beta cells promotes diacylglycerol spiking, local protein kinase C activation and insulin secretion**

A. Wuttke, A. Tengholm;

Medical Cell Biology, Uppsala University, Sweden.

**Background and aims:** The lipid diacylglycerol (DAG) is generated in the  $\beta$ -cell plasma membrane in response to receptor and nutrient stimuli and plays an important role in various signaling processes. DAG facilitates membrane recruitment and activation of C1-domain-containing proteins like protein kinase C (PKC), which in turn amplifies insulin secretion. We recently discovered that glucose and depolarizing stimuli evoke pronounced DAG spiking in the plasma membrane of  $\beta$ -cells. The effect is mediated by ATP released from the secretory granules acting in an autocrine manner on purinoreceptors to activate phospholipase C. We now investigated whether these short-lasting DAG-transients are able to activate PKC and if they influence insulin secretion.

**Materials and methods:** Various fluorescent translocation biosensors were expressed in MIN6  $\beta$ -cells or in primary mouse and human islet cells. DAG was measured with the two adjacent C1 domains of rat protein kinase Cy (C1aC1b-GFP or C1aC1b-mCherry), which translocate to the plasma membrane upon DAG formation. PKC-activity was detected with myristoylated alanine-rich C-kinase substrate (MARCKS-GFP), which dissociates from the plasma membrane upon phosphorylation by PKC. Insulin secretion kinetics was recorded with general receptor for phosphoinositides-1 (Grp1-4GFP), which detects phosphatidylinositol (3,4,5)-trisphosphate formation following autocrine insulin receptor activation.

**Results:** Glucose induced pronounced spikes (4–18 s duration,  $n=46$ ) of the plasma membrane DAG-concentration in MIN6 cells, primary mouse  $\beta$ -cells and human islet cells. Recordings from glucose-stimulated MIN6 cells co-expressing C1aC1b-mCherry and MARCKS-GFP showed that isolated DAG-spikes translated into transient PKC activation in spatially restricted regions of the plasma membrane. MARCKS-GFP dissociated from the membrane within 1 s after the increase in DAG, but MARCKS-reassociation was much slower than the duration of the DAG transient. Consequently, high frequency DAG-spiking tended to cause sustained MARCKS-GFP dissociation from the plasma membrane. The glucose-induced MARCKS-GFP dissociation, but not DAG spiking, was prevented by 0.5  $\mu$ M of the PKC-inhibitor staurosporine. A variant of MARCKS-GFP with mutated PKC phosphorylation sites failed to dissociate from the plasma membrane in response to glucose. Both DAG spiking and PKC activity was abolished by 10  $\mu$ M of the purinergic P2Y1 receptor antagonist MRS 2179, consistent with the involvement of feedback from exocytotically released ATP. Interestingly, MRS 2179 also reduced glucose-stimulated insulin secretion. Thus, the purinoreceptor inhibitor decreased both the initial amplitude of glucose-induced Grp1-4GFP translocation (reduction by  $41 \pm 10\%$ ,  $n=8$ ) and the area under the curve of the subsequent Grp1-4GFP oscillations (reduction by  $66 \pm 5\%$ ,  $n=10$  cells).

**Conclusion:** Glucose triggers spiking of the DAG-concentration in spatially restricted regions of the  $\beta$ -cell plasma membrane. This pattern translates into local and transient activation of PKC. The underlying feedback activation of purinergic receptors by exocytotically released ATP is important for appropriate control of insulin secretion.

## 384

**The role of klotho in pancreatic beta cells**

S. Schinner, B. Funk, F. Ülgen, W.A. Scherbaum;

Endocrinology, University Hospital Düsseldorf, Germany.

**Background and aims:** Klotho is a regulator of life-span and aging. Klotho deficient mice (“klotho mice”) show reduced insulin levels and increased insulin sensitivity. The role of klotho in pancreatic beta-cells is not known. Therefore, we have investigated the expression and function of klotho in beta-cells.

**Materials and methods:** Transient transfections of Ins-1 beta-cells. Isolation of primary mouse islets. Quantitative PCR and Western blots of islets of wild-type and klotho mice. Immunofluorescence. Proliferation assays.

**Results:** Klotho is expressed in pancreatic beta-cells of wild-type mice as assessed by immunofluorescence (co-localisation). The expression of klotho in pancreatic islets was confirmed on the RNA (quantitative PCR) and protein level (Western blots). In Ins-1 beta-cells exogenous klotho (100ng/ml) regulated the proliferation after chronic stimulation with Wnt3a: In contrast

to acute stimulation, chronic Wnt-stimulation inhibited cell proliferation by 80%. This effect was completely reversed by simultaneous treatment with recombinant klotho. Mechanistically, the activation of canonical Wnt-signaling (assessed by a Topflash reporter gene) by Wnt3a was inhibited by additional klotho protein.

**Conclusion:** Klotho is a novel protein expressed in pancreatic beta-cells. In vivo, klotho deficient mice show hypoplastic islets; in vitro klotho regulates beta-cell proliferation, suggesting klotho as a novel regulator of beta-cell function.

## 385

**ob/ob mouse islets exhibit reduced muscarinic M3 receptor expression and decreased secretory sensitivity to cholinergic receptor activation**

A.C. Hauge-Evans, C. Reers, Z. Tippu, S. Amisten, A. Vilches, S.J. Persaud, P.M. Jones;

Diabetes Research Group, King's College London, UK.

**Background and aims:** Islets are innervated by parasympathetic nerves which release acetylcholine (ACh) during feeding. In beta-cells the effect of ACh is mediated primarily via muscarinic M3 receptors (M3) leading to amplification of glucose-induced insulin secretion from the islets. Beta-cell specific knock-out of M3 results in reduced insulin secretion and impaired glucose tolerance so we therefore investigated the expression and function of M3 receptors in islets from a model of type 2 diabetes, the *ob/ob* mouse.

**Materials and methods:** M3 mRNA and protein expression was determined by qPCR and immunohistochemistry in islets isolated from 12-week old *ob/ob* and lean mice. Insulin content and secretion were assessed by radioimmunoassay and the latter normalized to protein content. Blood glucose levels were measured in non-fasted animals prior to islet isolation using a commercially available glucose meter.

**Results:** Non-fasting plasma blood glucose levels, average islet area and protein content were significantly increased in *ob/ob* mice (blood glucose:  $19.99 \pm 0.49$  mmol/l glucose vs.  $8.24 \pm 0.31$  mmol/l,  $p<0.01$ ,  $n=3$ ; area:  $84,195 \pm 7,678 \mu\text{m}^2$  vs.  $26,295 \pm 2,699 \mu\text{m}^2$ ,  $p<0.0001$ ,  $n=4$ ; protein content:  $1.84 \pm 0.19 \mu\text{g}/\text{islet}$  vs.  $1.20 \pm 0.09 \mu\text{g}/\text{islet}$ ,  $p<0.0001$ ,  $n=5$ ), whereas insulin content was unchanged (lean:  $77.76 \pm 11.04$  ng insulin/islet; *ob/ob*:  $62.64 \pm 5.78$  ng insulin/islet,  $p>0.2$ ,  $n=5$ ). M3 mRNA expression was decreased by 68% in *ob/ob* mouse islets compared to lean control islets (lean:  $0.97 \pm 0.09\%$  GAPDH expression, *ob/ob*:  $0.31 \pm 0.03\%$ ,  $p<0.005$ ,  $n=6$ ) and protein expression was reduced by 43% (lean:  $59.2 \pm 1.2\%$  total islet area, *ob/ob*:  $33.6 \pm 1.3\%$  total islet area,  $p<0.0001$ ,  $n=4$ ). Glucose-induced insulin secretion from *ob/ob* mouse islets was comparable to that of controls but their response to the acetylcholine analogue, carbamylcholine (CCh), was decreased by  $43 \pm 15\%$ . Thus, treatment with 0.5 mmol/l CCh resulted in a 4-fold increase in insulin secretion from control islets at 20mmol/l glucose ( $8.79 \pm 1.1$  vs.  $2.17 \pm 0.85$  ng insulin/ $\mu\text{g}$  protein  $p<0.05$ ,  $n=3$ ), whereas a 2.4-fold increase was observed in *ob/ob* mouse islets ( $5.02 \pm 1.12$  vs.  $2.12 \pm 0.36$  ng insulin/ $\mu\text{g}$  protein,  $p=0.09$ ,  $n=4$ ). To assess whether down-regulation of M3 in *ob/ob* mouse islets is linked to the specific genotype of the *ob/ob* mouse or is caused by the hyperglycaemic environment, M3 mRNA expression was assessed in islets from wild type ICR mice maintained in culture at 5.5 or 16 mmol/l glucose for 72h. Incubation at 16 mmol/l glucose significantly decreased M3 mRNA expression levels compared to those at 5.5 mmol/l (16 mmol/l:  $40 \pm 2\%$  time 0 control, 5.5 mmol/l:  $106 \pm 15\%$ ,  $p<0.05$ ,  $n=3$ ). Culture of islets in high glucose is reported to cause increased activation of protein kinase C (PKC) and this has been implicated in the down-regulation of GLP-1 receptors in *ob/ob* mouse islets. However, PKC-depletion by exposure to the PKC activator, PMA (0.5  $\mu\text{mol/l}$ ), for 72h did not increase M3 mRNA expression in islets from wild type ICR mice (106% control at 72h).

**Conclusion:** Parasympathetic regulation of insulin release is impaired in *ob/ob* mouse islets most likely due to reduced expression of M3 receptors. Our data suggest that the receptor down-regulation may be a PKC-independent consequence of the hyperglycaemic environment, and they imply that M3 receptors could be potential targets in the treatment of type 2 diabetes.

## 386

**Glucose-induced metabolic memory in min6 is camkii dependent**

G.J. Santos, S.M. Ferreira, L.F. Rezende, A.C. Boschero;

Department of Anatomy, Cell Biology and Physiology and Biophysics, State University of Campinas, Brazil.

**Background and aims:** Calcium-calmodulin kinase II (CaMKII), activated by the Ca<sup>2+</sup>-calmodulin complex, plays an important role in the Ca<sup>2+</sup>-signaling. In neurons, it is crucial for the generation of a process named Long Term Potentiation (LTP), responsible for formation of memory. It is also important for the process of neurotransmitters and hormones release. In this regard, CaMKII is increased in islets beta-cells during glucose-induced insulin secretion (GSIS), and animal lacking CaMKII shows a deficient glucose homeostasis. Therefore, we decided to evaluate if MIN6 cells possess the ability to form memory (acquire, store and retrieve information) in a CaMKII-dependent manner.

**Materials and methods:** MIN6 cells were exposed to 3 mM glucose (group 3mM) or to three pulses of 30 mM glucose of 1 h each, at intervals of 7 h (Group Pulse), with or without 10  $\mu$ M KN93 (a CaMKII specific inhibitor). After the stimulatory period, all the groups were maintained in a medium containing 3 mM glucose for 24 h (resting period). After, we assessed GSIS, CaMKII-phosphorylation, Calmodulin-pCaMKII association, and cell viability by RIA, Western Blot, Immunoprecipitation, and Flow cytometer, respectively.

**Results:** MIN6 cells secreted insulin in response to increasing concentrations of glucose, which correlated to increases with CaMKII phosphorylation and Calmodulin-pCaMKII interaction. Pulse treatment increased CaMKII phosphorylation and insulin secretion in both basal (2.8 mM) and stimulatory (16.7 mM) concentrations of glucose. Increase in both pCaMKII and insulin secretion over time (0–60'), even after removal of 16.7 mM glucose, were observed in the Pulse group. These alterations were not observed in the presence of KN93. In 3 mM group, there was an increase in Calmodulin-pCaMKII interaction, after exposure to 16.7 mM glucose, which was not observed in the Pulse group.

**Conclusion:** Even after 24 h, cells exposed to pulses of 30 mM glucose showed increased and prolonged GSIS, suggesting that MIN6 cells are able to acquire, store and retrieve information, that means to form memory. The inhibition of glucose-induced memory by KN93 indicates that CaMKII phosphorylation participates in this process.

**Immunofluorescence.** After 24 hours of the Pulse or 3mM treatment, MIN6 cells were exposed for 1 hour to 2.8 or 16.7 mM of glucose. After this period the cells were fixed and permeabilized, so, exposed, to an specific antibody.

## PS 015 Beta cell receptor tyrosine kinase and other signalling mechanisms

## 387

**Prevalent role of insulin receptor isoform A in insulin/IGF-I-induced beta cell hyperplasia**O. Escribano<sup>1,2</sup>, A. Gómez-Hernández<sup>1,2</sup>, C. Nevado<sup>1,2</sup>, G. García<sup>1,2</sup>,S. Fernández<sup>1,2</sup>, Y.F. Otero<sup>1,2</sup>, M. Benito<sup>1,2</sup>;<sup>1</sup>Biochemistry and Molecular Biology II, Complutense University of Madrid,<sup>2</sup>CIBERDEM, Barcelona, Spain.

**Background and aims:** Type 2 diabetes results from a combination of insulin resistance and impaired insulin secretion. While there is some debate about the primary defect in type 2 diabetes, insulin resistance is the most relevant pathophysiological feature in the prediabetic state. The main compensatory response to insulin resistance is the pancreatic beta cell hyperplasia to allow an increase in the insulin secretion. Previous work done in our laboratory showed a role of hepatic IGF-I in the compensatory beta cell hyperplasia observed in inducible liver-specific insulin receptor knockout mice (iLIRKO), a model of insulin resistance and type 2 diabetes. Moreover, several studies performed in pancreatic beta cells have shown differential insulin signaling depending on the type of activated insulin receptor isoform. However, the role of insulin receptor isoform A (IRA) or B (IRB) in the insulin/IGF-I-induced beta cell proliferation as well as glucose transport is poorly understood. Our aim was to generate a murine model of beta cells in order to study the role of insulin receptor isoforms in glucose transport, insulin/IGF-I-induced cell proliferation and also investigate the differential underlying mechanisms.

**Materials and methods:** Our laboratory had previously generated immortalized beta cell lines bearing IR (+/+), lacking IR (-/-), expressing exclusively IRA (IRA), or alternatively expressing IRB (IRB). In these cell lines, we measured the insulin/IGF-I-induced cell proliferation, glucose uptake and the underlying mechanisms involved were studied with standard biochemical techniques such as immunoprecipitation and Western blot.

**Results:** Cell proliferation studies have showed that cells expressing IRA are statistically more sensitive than those expressing IRB to the mitogenic response induced by insulin or IGF-I, being higher the mitogenic effect observed in response to IGF-I. Immunoprecipitation studies showed in IRA beta cells an enhanced Tyr-phosphorylation of IRS-1 in response to IGF-I and also an increased association of this protein with  $\alpha$ p85 compared to IRS-2. In summary, the main IGF-I signaling pathway occurred through IRA/IRS-1/ $\alpha$ p85/Akt/p70S6K. In the same way, IRA beta cells showed an increased glucose uptake as compared to control (+/+) and IRB beta cells under basal and insulin-stimulated conditions, this effect being likely owing to an enhanced association between the glucose transporters Glut-1 or Glut-2 with IRA and/or IGF-IR respectively.

**Conclusion:** Our results show a prevalent role of IRA in glucose uptake and IGF-I-induced pancreatic beta cell proliferation. These results could explain, at least partially, the molecular mechanisms involved in the compensatory beta cell hyperplasia in response to hepatic insulin resistance observed in iLIRKO mice.

## 388

**Pkb/akt isoforms and the regulation of pancreatic beta cell mass and function**M.G. Dietrich<sup>1,2</sup>, R.A. Zuellig<sup>1</sup>, G.A. Spinas<sup>1,2</sup>, O. Tschopp<sup>1,2</sup>, M. Niessen<sup>1,2</sup>;<sup>1</sup>Endocrinology, Diabetes & Clinical Nutrition, University Hospital of Zurich, Switzerland, <sup>2</sup>Competence Center for Systems Physiology and Metabolic Diseases, Swiss Federal Institute of Technology (ETH) Zurich, Switzerland.

**Background and aims:** Protein kinase B (PKB/Akt) regulates growth, proliferation and survival in different cell types. Three isoforms exist (PKBa/Akt1; PKB $\beta$ /Akt2 and PKB $\gamma$ /Akt3) and all are expressed in pancreatic  $\beta$  cells. No alterations in islet phenotype after deletion of individual isoforms of PKB were described. We have previously presented evidence that PKBa regulates  $\beta$  cell growth, proliferation and survival in mice. The aim of this study is to

determine the regulation and function of the three isoforms of PKB in pancreatic  $\beta$  cells.

**Material and methods:** Pancreatic islets were isolated from male rats (Sprague-Dawley). Human islets were obtained from the Juvenile Diabetes Research Fund (JDRF) and the European Consortium for Islets Transplantation's (ECIT) "Islets for Research Distribution Program". Isoforms of PKB were overexpressed from adenoviral vectors. Glucose-induced insulin secretion (GSIS) was assessed by ELISA or RIA after incubation of rat or human islets, respectively, at 2.8 mM glucose and subsequent stimulation with 16.7 mM glucose. Proliferation was measured by bromodeoxyuridine (BrdU) incorporation.  $\beta$  Cell apoptosis was induced with IL-1 $\beta$  and determined by TUNEL staining. Growth factor-induced isoform-specific signalling and activation of isoforms was analysed by Western blotting.

**Results:** Overexpression of PKBa increased the rate of proliferation in rat islets 2.2 fold (in human islets: 4.1 fold). Overexpression of PKB $\beta$  did not significantly increase proliferation. Overexpression of PKBa and PKB $\beta$  increased  $\beta$  cell size to the same extent. IL-1 $\beta$  increased the rate of cell death in human islets more than 2 fold. Only overexpression of PKBa protected the islets from IL-1 $\beta$ -induced apoptosis. In rat islets overexpression of PKB $\beta$  increased insulin content 2.4 fold (in human islets: 1.15 fold) but it decreased GSIS (around 20%). Insulin content and GSIS was not significantly changed after overexpression of PKBa. IGF-I activated PKB in INS-1E cells around 10 fold more than insulin. IGF-I activated all three isoforms, but PKB $\beta$  activation was 2 fold higher compared to PKBa and PKB $\gamma$ . Insulin did not activate PKB $\gamma$  and activated PKB $\beta$  around 5 fold more compared to PKBa. Combined stimulation with insulin and IGF-I was not synergistic and altered the activation pattern of isoforms. Phosphorylation of GSK-3 was higher after stimulation with IGF-1 as compared to insulin. Phosphorylation of 4EBP-1 was increased by insulin but decreased by IGF-1. Stimulation with IGF-1 reduced phosphorylation of I $\kappa$ B $\alpha$ , but insulin increased it about 1.5 fold. Phosphorylation of JNK was lowered by insulin and IGF-1 to a similar extent (about 25%).

**Conclusion:** Although insulin and IGF-I share the same post receptor signal transduction cascades they activate PKB isoforms differently in INS-1E  $\beta$  cells. Similarly, insulin and IGF-I are not equivalent in regulating targets downstream of PKB. Our findings in human and rat pancreatic islets indicate that only PKBa regulates proliferation and apoptosis in pancreatic  $\beta$  cells. PKB $\beta$  might be involved in the regulation of insulin synthesis. Our results strongly indicate that PKB isoforms have specific and redundant functions in pancreatic  $\beta$  cells.

## 389

**Impact of Akt1 and 2 on TBC1D1/D4 in response to glucose in beta cells** S. Rutti<sup>1</sup>, V. Kaddai<sup>2</sup>, F. Negro<sup>2</sup>, M. Kanzaki<sup>3</sup>, P.A. Halban<sup>1</sup>, K. Bouzakri<sup>1</sup>;

<sup>1</sup>Departement of Genetic Medicine and Development, University of Geneva, Switzerland, <sup>2</sup>Departement of Pathology and Immunology, University of Geneva, Switzerland, <sup>3</sup>Department of Biomedical Engineering, Tohoku University, Japan.

**Background and aims:** Protein kinase B/Akt plays a central role in beta-cells. The Rab-GAP AS160 (TBC1D4), an Akt substrate, is phosphorylated after glucose stimulation and downregulated in islets from type 2 diabetic individuals. However the impact of Akt isoforms on AS160 in response to glucose, as well as the expression and regulation in beta-cells of another Akt substrate, TBC1D1, remain to be investigated.

**Materials and methods:** Sorted rat primary beta-cells were transfected with siRNA to knockdown Akt1 and/or Akt2 (control = scrambled siRNA). Glucose stimulated insulin secretion (GSIS) was measured over 60 min. Proliferation (BrdU incorporation) and apoptosis (TUNEL) were assessed by immunofluorescence.

**Results:** Knockdown of Akt1 or Akt2 increased beta-cell apoptosis (Akt1:  $4.9 \pm 0.8\%$ , Akt2:  $2.4 \pm 0.17\%$  vs control:  $0.35 \pm 0.05\%$ ;  $p < 0.05$ ) and decreased proliferation (Akt1:  $1.49 \pm 0.14\%$ , Akt2:  $1.87 \pm 0.11\%$  vs control:  $10.22 \pm 0.3\%$ ;  $p < 0.05$ ), whereas only Akt1 knockdown decreased GSIS to  $0.99 \pm 0.31\%$  of total insulin content/h at 16.7 mM glucose, from  $2.3 \pm 0.22\%$  (control;  $p < 0.05$ ) without changing basal secretion. Both Akt isoforms regulated AS160/TBC1D4 phosphorylation in response to glucose. Akt2 knockdown decreased threonine-642 phosphorylation (western blot band density  $1.27 \pm 0.18$  vs  $4.51 \pm 0.83$  in control (arbitrary units);  $p < 0.05$ ), whereas Akt1 silencing decreased serine-588 phosphorylation ( $1.41 \pm 0.32$  vs  $4.58 \pm 0.48$  in control (arbitrary units);  $p < 0.05$ ). TBC1D1 was expressed in primary beta cells and phosphorylated (at serine 231 and 237) in response to glucose. However,

knockdown of Akt1 and 2 failed to modulate TBC1D1 phosphorylation (at serine 231 and 237).

**Conclusion:** Both Akt isoforms are involved in beta cell survival and proliferation, but only Akt1, not Akt2, appears to be implicated in GSIS. Both Akt1 and 2 regulate AS160/TBC1D4 phosphorylation in response to glucose. Akt2 is specifically involved in threonine-642 phosphorylation, whereas serine-588 phosphorylation is Akt1 dependent. TBC1D1 is expressed in primary beta-cells and is phosphorylated in response to glucose but such phosphorylation is not Akt-dependent.

## 390

**Influence of the ubiquitin-proteasome-system on the glucose sensor glucokinase in pancreatic beta cells**

A. Hofmeister-Brix<sup>1</sup>, S. Lenzen<sup>1</sup>, S. Baltrusch<sup>2</sup>;

<sup>1</sup>Institute of Clinical Biochemistry, Hannover Medical School, <sup>2</sup>Institute of Medical Biochemistry and Molecular Biology, University of Rostock, Germany.

**Background and aims:** In pancreatic beta cells, glucokinase (GK) acts as a glucose sensor and catalyses the rate-limiting step for initiation of glucose-induced insulin secretion. GK is mainly regulated on the posttranslational level. The ubiquitin-proteasome-system (UPS) has a pivotal role for protein turnover. In a recent study *in vitro* polyubiquitination of glucokinase was shown. However, studies regarding the interaction of the UPS and glucokinase in mammalian cells are still missing. The aim of this study was to analyse the protein stability and lifetime of glucokinase under treatment with the proteasome inhibitor Z-Leu-Leu-Leu-al (MG132) in MIN6 beta cells.

**Materials and methods:** MIN6 and primary mouse beta cells were incubated with 10  $\mu$ M MG132 and/or 10  $\mu$ g/ml cycloheximide (CHX) for 12 h. Cell viability was analysed by MTT-test, protein expression by Western blotting and immunofluorescence analyses. Glucokinase containing aggregate depositions were detected using the ProteoStat Aggresome Detection Kit. Glucokinase enzyme activity was determined using an enzyme coupled photometric assay. Insulin secretion was analysed by radioimmunoassay after stimulation with 3 or 25 mM glucose.

**Results:** Basal insulin secretion (3 mM glucose) and stimulated insulin secretion (25 mM glucose) were completely lost in MIN6 cells after a 12 h incubation with the proteasome inhibitor MG132 or CHX, an inhibitor of translation, alone or in combination. Cell viability was decreased by 30% under all experimental conditions. Glucokinase activity was reduced by 50% after treatment with MG132. However, the GK protein content increased as determined by Western blot analyses. In addition a second line with GK immunoreactivity was observed. After co-treatment with CHX this line was absent and GK activity was comparable to control conditions. Immunofluorescence analyses revealed that treatment of MIN6 and primary mouse beta cells with MG132 lead to an aggregation of GK in the cytoplasm. Such aggresomes were not observed in untreated cells and could be reduced by co-treatment with CHX.

**Conclusion:** Inhibition of the UPS for 12 h led to a total loss of glucose-induced insulin secretion in MIN6 cells, which could not be explained by the determined reduction in viability. The aggregation of GK in the cytosol after treatment with MG132 indicates that the specific protein lifetime is exceeded which results in protein missfolding and consequently in reduction of GK activity. Simultaneous inhibition of the translation with CHX increased the availability of long living chaperones which counteract this missfolding. This study points out the importance of the UPS for proper lifetime regulation of the glucose sensor GK in beta cells. Dysfunction of the UPS might contribute to the loss of glucose responsiveness in type 2 diabetes mellitus.

## 391

**The dual leucine zipper bearing kinase (DLK) levels are required for beta cell tasks by modulating PDX-1 activity and are impaired in human diabetic islets**N. Beeler<sup>1</sup>, B. Lefebvre<sup>2</sup>, R. Blouin<sup>3</sup>, P. Froguel<sup>4</sup>, F. Pattou<sup>2</sup>, G. Waeber<sup>1</sup>, A. Abderrahmani<sup>4,1</sup>;<sup>1</sup>Service of Internal Medicine, Centre Hospitalier Universitaire Vaudois and University of Lausanne, Switzerland, <sup>2</sup>Department of Endocrine Surgery, Lille University Hospital; European Genomic Institute for Diabetes, University of Lille, France, <sup>3</sup>Département de Biologie, Faculté des sciences, Université de Sherbrooke, Canada, <sup>4</sup>University of Lille, European Genomic Institute for Diabetes, Lille, France.

**Background and aims:** Pro-inflammatory cytokines play a critical role in decline of pancreatic b-cells and thereby in development of diabetes. One of the mechanisms triggered by cytokines involves activation of the mitogen activated protein kinase (MAPK) also called c-Jun N terminal kinase (JNK) pathway. Activation of JNK is achieved through a canonical signaling cascade involving the MAP Kinase Kinase Kinases (MAP3Ks) and MAP2Ks, which finally culminates to phosphorylation of JNK. The goal of this project was to determine the role of the Dual Leucine Zipper Bearing Kinase (DLK) as the MAP3K of JNK signaling and in b-cells tasks.

**Materials and methods:** DLK expression was either increased by overexpression of plasmids coding for DLK or decreased by RNA interference in isolated islets from rat or in the insulin producing INS-1E and MIN6 cell lines. mRNA and protein levels were assessed by quantitative real-time PCR and western blotting respectively. Apoptosis has been quantified by counting pyknotic nuclei. PDX-1 binding activity has been measured by electrophoretic mobility shift assay (EMSA).

**Results:** We first tested the presence of DLK in  $\beta$ -cells. DLK is expressed in pancreatic  $\beta$ -cells and in islets whereas it is undetectable in other cell types. This selective expression pattern of DLK results from the absence of the REST/NRSF transcription factor. Silencing of DLK decreases the cytokine-induced activation of JNK and this is associated with a reduced insulin expression and an increase in cells death evoked by pro-inflammatory cytokines. Reduction of DLK diminished the PDX-1 binding activity. On the opposite, overexpression of DLK promotes insulin production and increases PDX-1 binding activity. Expression of DLK is reduced in islets from individuals with diabetes.

**Conclusion:** DLK regulates the JNK signaling and is required for b-cell tasks by maintaining PDX-1 activity.

## 392

**Heparan sulfate in beta cells: does it play a role in FGF signalling?**A. Theodoraki<sup>1</sup>, Y. Hu<sup>1</sup>, S. Poopalasundaram<sup>1</sup>, S. Guimond<sup>2</sup>, J. Turnbull<sup>2</sup>, P. Bouloux<sup>1</sup>;<sup>1</sup>Centre for Neuroendocrinology, Royal Free Hampstead NHS Trust, London, <sup>2</sup>Institute of Integrative Biology, The University of Liverpool, UK.

**Background and aims:** Heparan sulfate (HS) proteoglycans are ubiquitous macromolecules present on cell membranes and extracellular matrix. They modulate the binding of heparin-binding growth factors to their receptors regulating the transmission of signals to the intracellular compartment. Fibroblast growth factors (FGFs) consist of a family of structurally related heparin-binding polypeptides. The FGF19 subfamily (FGF19, 21, 23) members have a weak affinity toward HS allowing them to escape into circulation and function as hormones. FGF21 protects beta cells from glucolipotoxicity. The aim of this study was to characterize the participation of HS chains in FGF signaling in beta cells. Additionally, to investigate if the glycosaminoglycan heparin protects the beta cell lines INS1 and MIN6 from reactive oxygen species induced cell death in vitro.

**Materials and methods:** INS1 and MIN6 cells were incubated with FGF1 or FGF21 for 2min-6hrs and signaling cascades were studied by Western blotting. HeparinaseIII was used (0.25-2.5IU/ml) to cleave endogenous HS chains. Enzymatic cleavage was confirmed with the antibodies 3G10 (western blots) and 10E4 (immunocytochemistry). Oxidative damage in cultured cells was induced with hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>). The mitochondrial membrane potential marker TMRE and the nucleic acid dead cell indicator ToPro3 were used in flow cytometry to identify healthy (TMRE+, ToPro-), early apoptotic (TMRE-, ToPro-) and dead cells (TMRE-, ToPro+). Porcine intestinal mucosal heparin (PIMH) was used at a concentration 5-250ug/ml.

**Results:** Timed signaling experiments with FGF1(10-100ng/ml) and FGF21(50-400ng/ml) identified the maximum ERK1/2 activation 5-10min post ligand addition; pAkt/tAkt ratio started to increase 10min post FGF1 or FGF21 addition. Cleavage of endogenous HS with heparinaseIII did not alter the FGF1 or FGF21 signaling cascade through ERK1/2. HeparinaseIII upregulated Akt phosphorylation ( $1.796 \pm 0.226$  after 2hr incubation with heparinaseIII 2.5IU/ml vs.  $0.903 \pm 0.09$  after incubation with vehicle control in MIN6). This was independent to FGF ligand addition and through the GSK3 $\beta$ , but not the mTOR pathway. Co-incubation with heparin did not inhibit signaling through Akt, while heparin alone had no effect. H<sub>2</sub>O<sub>2</sub> (250uM for 6hrs) reduced the number of INS1 TMRE positive cells from  $83.09\% \pm 3.97$  in control to  $22.49\% \pm 3.02$ . Heparin rescued a significant proportion of cells from oxidative damage: TMRE+ cells increased to  $41.19\% \pm 1.57$  ( $p < 0.005$ ) when H<sub>2</sub>O<sub>2</sub> and PIMH 50ug/ml were added concomitantly. TMRE+ cells were  $47.24\% \pm 1.53$  ( $p < 0.001$ ) when cells were pre-incubated with PIMH 50ug/ml for 24hrs followed by H<sub>2</sub>O<sub>2</sub> and PIMH 50ug/ml addition ( $n=4$ ).

**Conclusion:** Our results suggest that in the INS1 and MIN6 beta cells endogenous heparan sulfate chains are not indispensable for FGF signaling. HeparinaseIII upregulates the PI3K pathway. An important role of HS in beta cells seems to be the protection from reactive oxygen species induced cell death.

## 393

**Cross-talk between the c-Kit and insulin receptors enhance beta cell proliferation and function**

Z.C. Feng, A. Jan, J. Li, R. Wang;

Physiology &amp; Pharmacology, Children's Health Research Institute, the University of Western Ontario, London, Canada.

**Background and aims:** c-Kit, also known as a stem cell marker, is a member of the receptor tyrosine kinase superfamily. Expression of c-Kit is found on multiple tissues, including a subpopulation of beta cells. Interactions between c-Kit and its ligand, stem cell factor (SCF), play an integral role in the survival and function of beta cells, primarily via the PI3K/Akt/GSK3 $\beta$  signaling pathway. Our recent study demonstrated that mice with beta cell specific c-Kit overexpression had significant up-regulation of insulin receptor (IR) expression. Meanwhile, the contrary was observed in c-Kit loss-of-function (c-Kit<sup>Wv/+</sup>) mouse islets, suggesting that c-Kit modulates beta-cells by interacting with insulin signaling pathways. However, the underlining molecular mechanisms regarding this cross-talk have not been studied. The objective of the present study is to investigate the role of c-Kit with respect to IR and insulin receptor substrate (IRS) expression and the downstream signaling pathways implicated in modulating beta cell proliferation and function.

**Materials and methods:** INS-1 cells were cultured with either SCF or c-Kit siRNA. Expression and phosphorylation of c-Kit, IR, IRS, their downstream signaling pathways and islet transcriptional factors (e.g. Pdx1, MafA) was examined by qRT-PCR, western blot, co-immunoprecipitation, as well as double immunofluorescence assays.

**Results:** c-Kit and IR are both expressed in INS-1 cells. After SCF stimulation, we observed increased co-localization of c-Kit with IR as determined by double immunofluorescence and immunoprecipitation analyses. SCF-stimulated c-Kit and IRS1 phosphorylation occurred immediately (within 5 minutes) and reached peak level at 24 hours. Exogenous SCF treatment enhanced IR gene and protein expression ( $p < 0.05$ ), while significantly increasing pIRS1 ( $p < 0.01$ ) in INS-1 cells, and also lead to elevated Pdx-1 and MafA expression ( $p < 0.05$ ) when compared to controls. In line with these results, siRNA knock-down of c-Kit resulted in significantly decreased IR ( $p < 0.01$ ) and pIRS1 ( $p < 0.05$ ) protein levels with down-regulation of Pdx-1 and MafA expression. Furthermore, SCF/c-Kit-mediated improvements in cell proliferation, insulin, IR and pIRS1 expression were inhibited by wortmannin, indicating a requirement of the PI3K/Akt pathway.

**Conclusion:** These data suggest that c-Kit and IR may form a complex in INS-1 cells, and that cross-talk between these two receptors can enhance beta cell proliferation and function in a PI3K/Akt pathway-dependent manner. These data will advance our understanding of beta cell biology and enable us to develop better methods for the treatment of diabetes.

## 394

**Role of PTP1B in beta cell plasticity and function**R. Fernandez Ruiz<sup>1,2</sup>, E. Vieira<sup>1,2</sup>, P.M. García-Rovés<sup>2</sup>, R. Gomis<sup>1,2</sup>;<sup>1</sup>CIBERDEM, <sup>2</sup>IDIBAPS-Hospital Clinic, Barcelona, Spain.

**Background and aims:** Insulin resistance and  $\beta$  cell dysfunction are indispensable for the development of type 2 diabetes. In a prediabetic state,  $\beta$  cell mass and function are able to compensate for the diminished capacity of peripheral tissues to respond to insulin. Insulin has major autocrine effects on  $\beta$  cells, and in this sense, it is able to maintain both the glucose sensing machinery and promote  $\beta$  cell growth and survival. Protein tyrosine phosphatase 1B (PTP1B), a phosphotyrosine phosphatase anchored to the cytoplasmic face of the endoplasmic reticulum, inhibits insulin signalling through dephosphorylation of tyrosine residues in the insulin receptor and insulin receptor substrates. Due to the critical role that PTP1B plays regulating insulin action and its known effect in cell proliferation, our objective is to decipher the role of PTP1B in  $\beta$  cell mass and function.

**Materials and methods:** PTP1B knockout mice (KO) were kindly donated by Abbott Laboratories. At 8 weeks of age an intravenous glucose tolerance test (IPGTT) was performed by injecting 2g of glucose per Kg body weight, after an overnight fasting in knockout and wild type (WT) mice. Glycemia and insulin levels were measured from tail vein at different time points during the IGTT. Pancreas morphometry was performed by insulin and glucagon immunostaining. Studies of  $\beta$  cell proliferation and apoptosis were performed by ki67 and caspase3 immunostaining, respectively. Islets lysates were prepared in RIPA buffer for protein expression analysis.

**Results:** Whole body glucose tolerance was measured in WT and KO mice ( $n=13-14$ ) after a glucose load. Glucose levels are significantly lower in KO mice at 15, 30 and 60 minutes after glucose injection ( $p<0.05$ ), reflecting a higher glucose tolerance than in WT mice. The area under the curve is significantly lower in KO than in WT mice ( $23859.9\pm2544.58$  vs  $16282.9\pm2862.52$  mg\*min/dl). Insulin levels during the IPGTT shows an insulin secretion delay in KO mice versus WT. Insulin levels are significantly different ( $p<0.05$ ) both at 0, 15 and 60 minutes during the test between both groups. Analysis of  $\beta$  cell mass shows a significant increase ( $p<0.05$ ) in KO mice versus WT ( $81.87\pm11$  vs  $48.79\pm4$  ug/pancrea weight). In line with increased  $\beta$  cell mass a higher percentage of  $\beta$  cell proliferation ( $0.765\pm0.17$  vs  $0.072\pm0$ ), and a lower percentage of  $\beta$  cell apoptosis ( $1.37\pm0.0003$  vs  $4.58\pm0.0013$ ) was observed in KO versus WT mice. Moreover, these results of proliferation and apoptosis are in line with a higher Akt/PKB and Erk1/2, and a lower p53 protein expression in KO compared to WT mice. In order to assess the potential role of PTP1B in a pathological condition, we treated WT and KO mice with streptozotocin. After 7 weeks follow-up, the glycemia was significantly lower in KO mice, concomitantly with a higher  $\beta$  cell mass, higher  $\beta$  cell replication, and lower  $\beta$  cell apoptosis.

**Conclusion:** Ablation of PTP1B improves peripheral insulin sensitivity and increases  $\beta$  cell mass by mean of a higher  $\beta$  cell proliferation rate and a reduction in apoptosis. Thus, PTP1B is a potential therapeutic target for the treatment of diabetes due to improvements in insulin sensitivity and its positive actions in  $\beta$  cell plasticity and function.

## PS 016 Secretory granule and cytoskeleton dynamics in the beta cell

## 395

**Role of Rab3 family members in the regulation of beta cell insulin secretion**

C. Johné, S.E. Baltrusch;

Institute of Medical Biochemistry and Molecular Biology, University Rostock, Germany.

**Background and aims:** Rab proteins, that belong to the Ras superfamily are small GTPases with crucial functions in vesicle trafficking. Studies in the past decade revealed that Rab proteins, namely Rab27A and Rab3A, are also involved in insulin dense core vesicle trafficking and thus, impact insulin secretion from pancreatic beta cells. Rab27A has an effect on the replenishment of the docked granule pool and, on the coordination of pre-exocytotic stages. Rab3A interacts with different regulators promoting docking and exocytosis. Recent studies proposed that another member of the Rab family, Rab3B, has a pivotal function in beta cell insulin secretion. Therefore the aim of this study was to explore the role of Rab3B in beta cells.

**Materials and methods:** Mouse islets, murine tissues and MIN6 beta cells were analyzed for Rab3 expression by RT-PCR, Western Blot and immunofluorescence analyses. For overexpression of Rab3A and Rab3B, cells were transiently transfected. Down regulation of Rab proteins was evoked by lentiviral shRNA transduction. Glucose-induced insulin secretion was measured by ELISA.

**Results:** Both, Rab3A and Rab3B are expressed in mouse islets, brain, liver and pancreas as well as in MIN6 beta cells. In total pancreas tissue Rab3A was expressed 10-fold higher than Rab3B. In contrast, an equal amount of Rab3A and Rab3B was detectable in isolated islets, indicating the pivotal role of Rab3B in endocrine tissue. Immunofluorescence analyses revealed a punctate distribution of Rab3A and Rab3B in beta cells. Surprisingly, the observed Rab3A and Rab3B vesicle-like localization showed only little colocalization with each other. Rab3A displayed a higher degree of colocalization with insulin granules than Rab3B. Islets and MIN6 cells were cultured for 72 h in the presence of palmitate at high or low glucose concentrations. The expression of both, Rab3A and Rab3B decreased by palmitate incubation in MIN6 cells. However, a significant increase in the expression level of both proteins was observed in islets. Furthermore the impact of Rab3 proteins on insulin secretion was studied. Neither Rab3A nor Rab3B overexpression in MIN6 beta cells modified insulin secretion. In contrast, knocking down Rab3A or Rab3B protein expression resulted in a significant reduction of glucose-induced insulin secretion.

**Conclusion:** Our study confirmed the key role of Rab3A in regulation of murine beta cell insulin secretion. A recent publication suggested that rather Rab3B is the crucial regulator of insulin dense core vesicle trafficking in human islets. We could show for the first time in mouse islets Rab3B expression and alterations in the expression level by means of nutrient. Thus, Rab3B and Rab3A are crucial factors in beta cell function and reduced or imbalanced expression may contribute to progression of type 2 diabetes mellitus.

## 396

**Glucose-induced ERK1/2 activation is permissive for receptor-operated potentiation of insulin secretion through cytoskeletal remodelling**

J.E. Bowe, A. Chander, S.J. Persaud, P.M. Jones;

Diabetes Research Group, King's College London, UK.

**Background and aims:** We have previously shown that several receptor-operated secretagogues, including kisspeptin, the cannabinoid 2 receptor agonist JWH015, the GLP-1 analogue exendin-4 and the CaR agonist A568, potentiate glucose-induced insulin release via an ERK1/2-dependent pathway. The present study aimed to further examine the mechanism by which ERK1/2 modulate receptor-operated potentiation of insulin release and to investigate whether actin dissociation might be involved.

**Materials and methods:** Isolated mouse islets were incubated for 1hr in a physiological salt solution and insulin release was measured by radioimmunoassay. Activation of ERK1/2 was measured by western blotting for phos-

pho-ERK relative to total ERK immunoreactivity. Dispersed mouse islet cells were incubated for 10 min in a physiological salt solution containing various treatments, before fixation in 4% paraformaldehyde and staining for actin filaments with rhodamine-phalloidin.

**Results:** Neither kisspeptin, A568 nor exendin-4 significantly stimulated insulin release from islets at a sub-stimulatory glucose concentration (2 mmol/L glucose control:  $0.14 \pm 0.02$  ng/islet/h, 1  $\mu$ mol/L kisspeptin:  $0.14 \pm 0.02$ , 10  $\mu$ mol/L A568:  $0.16 \pm 0.05$ , 100 nmol/L exendin-4:  $0.13 \pm 0.04$ ,  $n=9$ ,  $p>0.2$ ). However, in the presence of 10  $\mu$ mol/L okadaic acid and 100  $\mu$ mol/L sodium pervanadate, which activated ERK1/2 through inhibition of dephosphorylation, these secretagogues significantly increased insulin release from islets incubated at 2 mmol/L glucose (1  $\mu$ mol/L kisspeptin:  $381 \pm 52\%$  basal, 10  $\mu$ mol/L A568:  $456 \pm 39\%$ , 100 nmol/L exendin-4:  $322 \pm 30\%$ , 10  $\mu$ mol/L JWH015:  $210 \pm 19\%$ ,  $n=9$ ,  $p<0.05$ ). Dissociation of actin filaments by 1 h treatment of islets with either 10  $\mu$ mol/L cytochalasin-B or 10  $\mu$ mol/L latrunculin enabled all receptor-operated secretagogues tested to significantly stimulate insulin release from islets incubated at 2 mmol/L glucose (islets treated with 10  $\mu$ mol/L cytochalasin-B: 1  $\mu$ mol/L kisspeptin:  $315 \pm 32\%$  basal, 10  $\mu$ mol/L A568:  $407 \pm 35\%$ , 100 nmol/L exendin-4:  $351 \pm 24\%$ , 10  $\mu$ mol/L JWH015:  $192 \pm 29\%$ ,  $n=9$ ,  $p<0.05$ . Islets treated with 10  $\mu$ mol/L latrunculin: 1  $\mu$ mol/L kisspeptin:  $287 \pm 27\%$  basal, 10  $\mu$ mol/L A568:  $816 \pm 138\%$ , 100 nmol/L exendin-4:  $427 \pm 59\%$ , 10  $\mu$ mol/L JWH015:  $245 \pm 39\%$ ,  $n=9$ ,  $p<0.2$ ). Furthermore, a decrease in filamentous actin was observed in primary  $\beta$ -cells at 20 mmol/L glucose compared to  $\beta$ -cells incubated in the presence of 2 mmol/L glucose (2 mmol/L glucose: staining intensity  $56.9 \pm 9.3$  arbitrary units, 20 mmol/L glucose:  $24.2 \pm 4.4$ ,  $n=38-52$ ,  $p<0.05$ ) and this dissociation of actin filaments was reduced by the MEK inhibitor PD098059 (20 mmol/L glucose + 50  $\mu$ mol/L PD098059:  $39.5 \pm 4.1$  arbitrary units,  $n=49$ ,  $p<0.05$ ).

**Conclusion:** These observations suggest that the permissive role that ERK1/2 activation plays in the potentiation of glucose-induced insulin secretion by some receptor-operated agonists is mediated through actin dissociation.

### The synaptotagmin isoform 11 interacts with components of the RNA-induced silencing complex RISC at the ER-Golgi intermediate compartment

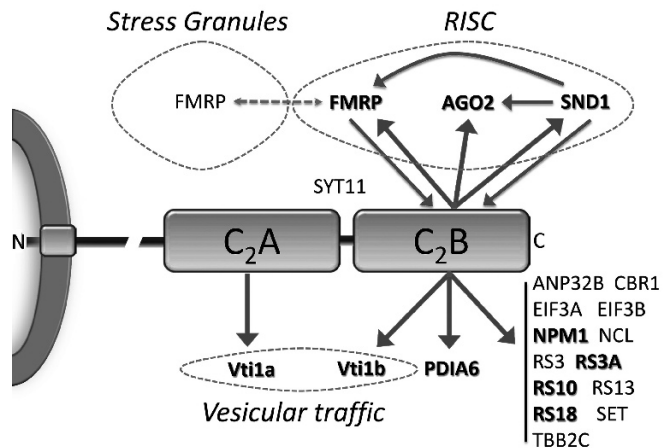

J. Lang<sup>1</sup>, A. Milochau<sup>1</sup>, V. Lagrèe<sup>1</sup>, S. Chaignepain<sup>1</sup>, A. Lajoix<sup>2</sup>, I. Garcia-Arcos<sup>3</sup>, C. Monterra<sup>1</sup>, L. Coudert<sup>1</sup>, J.-M. Schmitter<sup>1</sup>, B. Ochoa<sup>3</sup>,  
<sup>1</sup>Université de Bordeaux, Pessac, France, <sup>2</sup>Faculté de Pharmacie, Université Montpellier 1, France, <sup>3</sup>Department of Physiology, University of the Basque Country, Bilbao, Spain.

**Background and aims:** Synaptotagmins form a family of transmembrane proteins that contains two cytosolic  $C_2$  domains. Whereas some isoforms co-operatively bind calcium and membrane phospholipids via their  $C_2$  domains, others contain calcium-insensitive  $C_2$  domains. The function of several  $Ca^{2+}$ -insensitive isoforms have been characterized in detail in post-Golgi trafficking including exocytosis, where they act as regulators of membrane fusion. In contrast, the localization and the biological role of most other isoforms are still poorly understood. We have therefore addressed the localization and interactions of the calcium-insensitive isoform synaptotagmin 11 to obtain insight into its potential role.

**Materials and methods:** The polyclonal antibody against syt11 was produced by immunization of rabbits with the synthetic peptide CHQQAEEKKHK-TPPYK (amino acids 40–54 of rat syt11) coupled to KHL. Antibodies were further immunopurified. Islets, HIT-T15, MIN6 and INS-1E were cultured as previously published. Immunoprecipitations and pull-down experiments were performed on Triton X-100 extracts from INS-1E cells. Recombinant proteins were purified according to standard procedures. Peptide data were acquired on a MALDI Q-TOF Premier mass spectrometer used in MS/MS mode (Waters, Manchester, UK) and proteins were identified using the MASCOT software.

**Results:** In islets and clonal beta-cells synaptotagmin 11 localized in the early secretory pathway, at the ER/Golgi intermediate compartment (ERGIC) and in the cis-Golgi, as evidenced by subcellular fractionation and immunofluorescence. Novel binding partners of synaptotagmin 11 in INS-1E cells were identified by affinity binding assays coupled to mass spectrometry. A number of the binding partners identified here had been assigned previously to ER/Golgi derived-vesicles or ERGIC and a majority of them is linked to RNA synthesis, translation and processing. Whereas the  $C_2A$  domain of synaptotagmin 11 interacted with the Q-SNARE Vti1a, its  $C_2B$  domain interacted with the SN domains of the

staphylococcal nuclease domain-containing protein 1 (SND1), Ago2 and the fragile X mental retardation protein (FMRP), known components of the RNA-induced silencing complex (RISC). Upon induction of stress, only FMRP, but neither SND1 nor syt11 distributed with stress granules. **Conclusion:** Synaptotagmin 11 recruits RISC early in the secretory pathway via its  $C_2B$  domain and may provide a link between gene regulation by microRNAs and membrane traffic in the early secretory pathway.

### ICA512 regulates the expression of villin-1, insights into the function of this actin binding protein in pancreatic beta cells

H. Mziaut<sup>1</sup>, D. Schumann<sup>2</sup>, T. Hildebrandt<sup>2</sup>, B. Mulligan<sup>1</sup>, A. Altkrüger<sup>1</sup>, C. Münster<sup>1</sup>, M. Lee<sup>3</sup>, S. Kauschke<sup>2</sup>, M. Mark<sup>2</sup>, P. Eickelmann<sup>2</sup>, M. Solimena<sup>1</sup>,  
<sup>1</sup>Molecular Diabetology, Medical School, University of Technology Dresden, Germany, <sup>2</sup>Cardiometabolic Research, Boehringer Ingelheim Pharma GmbH & Co. KGn, Biberach, Germany, <sup>3</sup>Department of Medicine, Samsung Medical Center, Seoul, Republic of Korea.

**Background and aims:** Insulin-containing secretory granules are formed at the trans-Golgi network and transported close to the plasma membrane for exocytosis. Stimulation of insulin secretion causes a rearrangement of microfilaments, but information about the interplay between insulin granules and cortical actin is still incomplete. Islet cell autoantigen 512/IA-2 (ICA512) is an intrinsic membrane protein of neurosecretory granules and a member of the receptor protein-tyrosine phosphatase family lacking phosphatase activity. Genetic deletion of ICA512 in mice results in mild glucose intolerance and decreased glucose-responsive insulin secretion. We have previously shown that ICA512 tethers insulin granules to actin microfilaments via its interaction with  $\beta 2$ -syntrophin. To gain further insights into how ICA512 regulates insulin secretion we have now compared the gene expression profiles of islets from ICA512<sup>-/-</sup> mice and control littermates.

**Materials and methods:** These studies included 2 groups of knockout mice, ICA512<sup>-/-</sup>, vil<sup>-/-</sup> and their control littermates, and insulinoma cell lines INS-1 and MIN6 cells. Statistical analyses were performed using the unpaired Student's t test.

**Results and Conclusion:** We report that ICA512<sup>-/-</sup> islets express significantly lower levels of villin-1, as first assessed by microarray assays and deep sequencing and then corroborated by immunocytochemistry and western blotting. Villin belongs to the gelsolin protein family and regulates the absorptive and secretory function of epithelial cells by modulating F-actin polymerisation/depolymerisation. Accordingly, we found that villin-1 is enriched at the cell cortex of pancreatic  $\beta$ -cells. As in mouse islets, downregulation of ICA512 in insulinoma Min6 and INS-1 cells by siRNA reduced villin expression. Furthermore, we found that villin regulates insulin secretion, presumably being required for proper changes in the organisation of the F-actin architecture. Preliminary evidence, in particular, suggests that downregulation of villin-1 in Min6 cells affects the processive movement of insulin granules. These results are consistent with the role of gelsolin-related proteins as regulators of exocytosis through their  $Ca^{2+}$ -dependent actin-bundling, -capping, and -severing activities. They also strengthen the close relationship between ICA512 and the cortical cytoskeleton. Specifically we propose that downregulation

lation of villin in ICA512-/- mice represents a compensatory adaptation to sustain the secretion of peptide hormones, including insulin.

### Pre-exocytotic mobility of insulin granules in the submembrane space

K. Schumacher, K. Hatlapatka, M. Matz, K. Baumann, I. Rustenbeck;  
Technical University of Braunschweig, Germany.

**Background and aims:** Current hypotheses of insulin exocytosis provide that a pool of membrane-adjacent secretory granules exists which are in a primed and docked state and await one final trigger, a depolarization-induced influx of  $\text{Ca}^{2+}$ . This pool is held responsible for the first phase of glucose-induced insulin secretion. A number of recent observations have put this hypothesis into question.

**Materials and methods:** Granules in the immediate vicinity of the plasma membrane were visualized by transient transfection of insulin-secreting MIN6 cells with an insulin-EGFP fusion protein and imaged by TIRF microscopy. The cells were continuously perfused with HEPES-buffered Krebs-Ringer medium (37.0 °C), which was saturated with 95%  $\text{O}_2$  and 5%  $\text{CO}_2$ . The TIRF field had a calculated decay constant of 84 nm. The image files were evaluated by an in house written program (MATLAB 7.6.0) to achieve a complete observer-independent quantification. Granule mobility in the X/Y-plane was described by using the concept of the “caging diameter” (CD). The free cytosolic  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) of MIN6 cells was measured with the Fura technique.

**Results:** Like primary mouse islets, MIN6 pseudo-islets responded to the depolarization by 40 mM KCl and the resulting increase of the  $[\text{Ca}^{2+}]_i$  with a strong increase in insulin secretion. In single MIN6 cells nearly 80% of the granules that were released by a perfusion with 40 mM  $\text{K}^+$  during 25 s acquisition sequences were already present in the first image of the sequence. The fastest itinerary took 3 s from granule arrival to exocytosis. Given that the residence time in the submembrane space prior to exocytosis was clearly different, and assuming that a certain pattern of mobility might precede exocytosis, the CDs of the last 3 s before fusion were calculated after normalizing the residence time to the time point of exocytosis. Granules that were released had initially a low CD value of about  $72 \pm 16$  nm which increased ( $p = 0.017$ , ANOVA) continuously to  $185 \pm 28$  nm at 0.125 s before fusion. Two types of control were considered. Firstly, the CDs of all those granules were determined that departed from the evanescent field in either direction and were present for 3 s or longer. Secondly, the CDs of a subgroup were determined, namely those granules that were the closest (both temporal and spatial) to the exocytoses. The former control had a CD value of about 140 nm and did not show a significant change ( $p = 0.324$ , ANOVA) in the 3 s time interval. However, the latter control which initially had also a CD value of about 140 nm showed a marginally significant increase ( $p = 0.078$ , ANOVA) to values of about 190 nm during the last 0.5 s.

**Conclusion:** Observer-independent quantification of the entire submembrane granule population by TIRF microscopy showed that pre-exocytotic granules significantly increased their mobility in the X/Y-plane during the last 3 seconds before fusion. This further calls into question the concept of a static membrane-attached granule pool as the correlate of the first phase secretory response.

### Syntaxin recruitment to the release site marks the transition of insulin granules from tethered to docked

S. Barg, N. Gandasi;  
Medical Cell Biology, Uppsala University, Sweden.

**Background and aims:** The SNARE proteins syntaxin1A is required for both docking and exocytosis of insulin granules. Reduced expression of syntaxin is observed in type-2 diabetes and complete lack of syntaxin prevents granule docking in mice. Syntaxin clusters into raft-like nanodomains of up to 80 molecules in the plasma membrane, which may act as docking receptor for insulin granules. Here we tested two predictions of this model: syntaxin should be present at the release site before the granule docks, and association with a syntaxin cluster should mark a granule as docked and ready for exocytosis.

**Materials and methods:** Insulin-secreting Ins1 cells were co-transfected with syntaxin1a-EGFP and a granule marker and imaged using TIRF microscopy. **Results:** Syntaxin formed small clusters (<100nm) in the plasma membrane, often near docked granules. The clusters were stationary over several minutes, but exhibited striking intensity variations with a period of a few seconds. Single-molecule imaging showed that individual syntaxin molecules were mobile but occasionally captured near a granule, for a short time (<1s). Only granules associated with a syntaxin cluster remained stably docked over several minutes. Surprisingly, when a granule approached the plasma membrane it did not search for an empty syntaxin cluster. Instead, such clusters formed during granule docking at a rate of 0.6s-1. About two-thirds of the granules only visited the plasma membrane and did not stably dock; in these cases syntaxin did not accumulate. The rate at which visiting granules converted into stably docked was 0.1s-1. A syntaxin-derived peptide interfered with both cluster localization and prevented the transition of granules to stably docked. Finally, spontaneous loss of syntaxin clusters predicted subsequent loss of the granule by undocking.

**Conclusion:** We propose that visiting granules induce clustering of syntaxin in the target membrane, which then acts as their own docking receptor. This process marks the transition from loosely tethered to stably docked and occurs on a timescale consistent with rapid cellular signaling. It may thus underlie the docking defect observed with reduced expression of syntaxin.

### Activated Cdc42-bound-IQGAP1 determines the cellular endocytic site in pancreatic beta cells

T. Kimura, M. Yamaoka, S. Taniguchi, I. Niki;  
Pharmacology, Oita University, Faculty of Medicine, Oita, Japan.

**Background and aims:** Intracellular protein and lipid trafficking is a fundamental cellular process that is required for the generation of specialized membranous organelles and for communication between these organelles. Recruitment of specific molecules to specific membrane sites is essential for this trafficking. Rab27a, a member of the Rab GTPase family, has been considered to act as a molecular switch for exocytosis in insulin secretion, cycling between an ‘active’ GTP-bound and an ‘inactive’ GDP-bound state. We previously showed that GDP-bound Rab27a is not an ‘inactive’ form but is in fact an ‘active’ form that regulates endocytosis through the GDP-dependent effector coronin 3. In the present study, we searched for another GDP-dependent Rab27a effector to investigate GDP-dependent roles of Rab27a in the pancreatic beta cell.

**Materials and methods:** Extracts from the insulin-secreting beta-cell line, MIN6, were applied to a GDP-bound Rab27a affinity column to investigate GDP-bound Rab27a interacting proteins. For immunostaining and live imaging, MIN6 cells were transfected with plasmid DNAs or siRNA using Lipofectamine 2000. After 24 h of transfection, the cells were analyzed with a confocal laser microscopy system. For the observation of endocytosis, cells were incubated in culture media containing the endocytosis marker. The rate of cells with cytoplasmic pattern was evaluated.

**Results:** We identified IQGAP1, an effector of GTP-bound Cdc42, as another GDP-dependent effector of Rab27a. We found that IQGAP1 interacted with GDP-bound Rab27a when it formed a complex with GTP-bound Cdc42. IQGAP1 regulated endocytosis of insulin secretory membranes. Silencing of IQGAP1 inhibited endocytosis and the glucose-induced redistribution of Rab27a and coronin 3 to the cell periphery. These processes could also be inhibited by disruption of the trimeric complex with dominant-negative IQGAP1 and Cdc42.

**Conclusion:** These results indicate that activation of Cdc42 in response to the insulin secretagogue glucose recruits endocytic machinery, including GDP-bound Rab27a and coronin 3, to IQGAP1 at the cell periphery and regulates endocytosis at this membrane site.

**Nonmuscle myosin II is involved in focal adhesion and actin remodelling controlling glucose-stimulated insulin secretion**

C. Arous, D. Rondas, P.A. Halban;

Dpt. Genetic Medicine and Development, University Medical Center, University of Geneva, Switzerland.

**Background and aims:** Regulation of insulin secretion from the beta cell is a key determinant of normal glucose homeostasis. Actin and focal adhesion (FA) remodelling, and activation of the ERK1/2 signalling pathway are essential for increased insulin exocytosis upon glucose stimulation. Nonmuscle myosin II isoforms may have a central role in glucose-stimulated insulin secretion (GSIS) because of their role in actin remodelling and FA maturation in other cell events. Furthermore, divergence of function between myosin IIa and IIb suggests possible isoform-specific roles in beta cells. Myosin light chain (MLCK) and Rho kinase (ROCK) are upstream regulators of myosin II that have been shown to be involved in GSIS. The aim was to elucidate the implication of myosin IIa and IIb in beta cell actin cytoskeleton remodelling, FA maturation and granule trafficking involved in GSIS.

**Materials and methods:** Three inhibitors were used to study the impact of myosin II regulation in GSIS: blebbistatin, specific inhibitor of myosin II; ML7, selective inhibitor of MLCK; Y23632, ROCK inhibitor. All studies (except live imaging) were performed using sorted rat primary beta cells cultured in monolayer, on extracellular matrix. After 2h at low glucose (2.8mM), cells were stimulated up to 60 min at high glucose (16.7mM). Insulin was measured by radioimmunoassay. Protein levels and phosphorylation were determined by western blot. Immunofluorescence and live cell imaging were used to study dynamic changes in localization and appearance of FA proteins, focal adhesion kinase (FAK) and paxillin (PAX), actin cytoskeleton and insulin granules. Live cell imaging was performed on MIN6B1 (mouse beta cell line) at 0mM (basal) and 20mM glucose (stimulated). Data are mean  $\pm$  SEM (n=3–4 independent experiments).

**Results:** Myosin II and MLCK inhibitors significantly decreased GSIS by 33.4 $\pm$ 5.2% and 25.5 $\pm$ 3.5% respectively whereas the ROCK inhibitor increased GSIS about 2-fold as previously shown. Glucose stimulation led to bundling of actin filaments, with FAK and PAX phosphorylation and their localization in small filopodial extensions resembling maturing FAs. ROCK inhibition caused disassembly of glucose-induced actin stress fibres in the central portion of the cell and resulted in large FAs containing pFAK and PAX without significant effect on FA number. MLCK inhibition was without apparent effect on actin remodelling induced by glucose but resulted in a 53.8 $\pm$ 3.3% decrease of ERK1/2 phosphorylation and 54.1 $\pm$ 5.1% decrease of FA number. Blebbistatin completely blunted actin reorganization and insulin granule movement, and decreased by 88.7 $\pm$ 6.0% FA protein recruitment to the membrane after glucose stimulation. Finally, glucose induced reorganization of both myosin IIa and IIb into fibres co-localizing with actin but not with PAX at filopodial extensions. Interestingly, only glucose-induced myosin IIa reorganisation was blunted by MLCK inhibition.

**Conclusion:** Myosin II seems to be directly involved in GSIS acting through actin cytoskeleton and FA remodelling and granule trafficking. Our results indicate an indirect role of myosin II on FA maturation and stabilization, likely through actin and/or microtubule regulation with MLCK and ROCK as upstream regulators. Finally, our data suggest a distinct regulation of FA formation induced by glucose through the MLCK-myosin IIa-ERK1/2 pathway.

**Potential role of Huntingtin-associated protein-1 in regulating insulin secretion from beta cells**G. Li<sup>1</sup>, B. Xie<sup>1</sup>, R. Luo<sup>1</sup>, X.-J. Li<sup>2</sup>, Y.-M. Bee<sup>3</sup>;<sup>1</sup>Dept of Clinical Research, Singapore General Hospital, Singapore, <sup>2</sup>Dept of Human Genetics, Emory University, Atlanta, USA, <sup>3</sup>Dept of Endocrinology, Singapore General Hospital, Singapore.

**Background and aims:** Huntingtin-associated protein-1 (HAP1) is involved in the pathogenesis of Huntington's disease. It may act as a scaffold in the assembly of protein complexes and participate in intracellular trafficking. There is evidence that HAP1 is expressed in pancreatic islets. We have detected HAP1 expression in insulin-secreting INS-1  $\beta$ -cells and thus investigated its potential roles by small RNA interference technology.

**Materials and methods:** INS-1 cells were transfected with a pool of siRNA oligos targeting HAP1 for 48–72h to knock down its expression as assessed by

qRT-PCR and immunoblotting. Subsequently, insulin secretion induced by glucose and other secretagogues was measured. The key events for stimulation of insulin secretion, including glucose metabolism, membrane potential depolarization and intracellular free  $\text{Ca}^{2+}$  levels ( $[\text{Ca}^{2+}]_i$ ), were also assessed in these cells.

**Results:** Transfection of HAP1-targeting siRNA oligos for 48–72h markedly knocked down HAP1 by >80% as assessed by qRT-PCR and immunoblotting in INS-1 cells. HAP1 knockdown significantly reduced glucose-stimulated insulin secretion up to 30%, without altering insulin content in INS-1 cells. However, the proximal signaling events of the signaling cascade implicated in regulating glucose-stimulated insulin secretion were not affected by HAP1 knockdown; these include the glucose metabolism, glucose-induced depolarization of membrane potential and elevation of  $[\text{Ca}^{2+}]_i$ . In addition, the effect of tolbutamide (an ATP-sensitive potassium channel blocker) on membrane potential depolarization remained intact, whereas its ability to stimulate insulin release was inhibited following HAP1 knockdown. Moreover, high (40 mM) KCl-induced insulin secretion was also significantly reduced in these cells, though  $[\text{Ca}^{2+}]_i$  elevation by high KCl was not affected. These results suggest that a step after  $[\text{Ca}^{2+}]_i$  rise in the insulin secretion scenario involves HAP1. On the other hand, glucose-stimulated insulin secretion was markedly potentiated by forskolin and IBMX which elevate cAMP level and activation of PKA. Interestingly, there was no significant change in glucose-stimulated insulin secretion in the presence of forskolin or IBMX after HAP1 knockdown in INS-1 cells.

**Conclusion:** All these results indicate that HAP1 knockdown interfered with glucose-stimulated insulin secretion beyond the steps of membrane depolarization and  $[\text{Ca}^{2+}]_i$  rise, and such inhibition could be relieved by cAMP elevation. Thus, HAP1 may participate in the regulating insulin secretion by involved in intracellular vesicles trafficking and exocytosis, such as motivating insulin-containing granules from reserved pool to docked pool in order to meet the need of rapid insulin release.

**Proteomic approach to search for differentially expressed proteins between human pancreatic islets and human insulinomas**L.F. Terra<sup>1,2</sup>, P.C. Teixeira<sup>3</sup>, R.A.M. Wailemann<sup>1,2</sup>, A. Zelanis<sup>4</sup>, G. Palmisano<sup>5</sup>, E. Cunha-Neto<sup>3</sup>, J. Kalil<sup>3</sup>, L. Labriola<sup>1,2</sup>, M.C. Sogayar<sup>1,2</sup>;<sup>1</sup>Departamento de Bioquímica, Instituto de Química, Universidade de São Paulo, Brazil, <sup>2</sup>NUCEL, Universidade de São Paulo, Brazil, <sup>3</sup>InCor, FM-USP, São Paulo, Brazil, <sup>4</sup>Instituto Butantã, São Paulo, Brazil, <sup>5</sup>Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark.

**Background and aims:** Transplantation of isolated pancreatic islets is an alternative treatment for type 1 Diabetes; being limited by the shortage of organ donors. Ex-vivo culture prior to transplantation appears as an attractive alternative; however, maintenance of human islets in culture remains a difficult task. Only a few human beta-cell lines are available, therefore, culture of insulinomas, pancreatic tumors arising from beta-cells, may provide a tool to study cell proliferation and insulin synthesis and secretion. We have developed three human beta-cell lines (APM, VGA, CPR) which maintain the antigenic characteristics and insulin secretion profiles of the original tumors. In order to better characterize these beta cell lines, we set out to identify proteins displaying altered expression levels between normal and neoplastic beta cells.

**Materials and methods:** Identification of differentially expressed proteins was achieved through 2-dimensional gel electrophoresis (2D-DIGE) and mass spectrometry. Results were confirmed by western blotting.

**Results:** An average of 1,800 spots was detected; approximately 1% of which was differentially regulated. So far, we have been able to identify nine of these proteins, namely: a) Caldesmon, described as being involved in cytoskeletal organization, and NR6A1, which plays a putative role in germ cell development during gametogenesis, are both up-regulated in islets, when compared to the human insulinomas; b) MAGE-A2, described as being expressed in different tumors, but never in normal cells, 14-3-3 protein, whose classical role is to inhibit PKC and promote cell death inhibition, OTUD7A, whose putative function is presenting deubiquitinating activity, and Dermcidin, which has already been described as playing a role in cell migration and as a survival factor, were all found to be up-regulated in the APM cell line. None of these proteins had previously been described either in human insulinomas or in human islets; c) GAPDH, from the glycolytic pathway; PKN1, responsible for the regulation of microfilaments and NEUA, which catalyzes activation of the

N-acetylneuraminic acid, were also identified, but did not display differential expression.

**Conclusion:** Collectively, these observations not only prompt research towards successful establishment of bioengineered human beta-cells, providing a large and much needed source of cultured human beta-cell tissue for experimentation, but, could also lead to generation of therapeutic tools for insulinomas, since these differentially expressed proteins could be related to the malignancy displayed by these cells.

## PS 017 Insulin secretion and exocytosis: novel aspects

### 405

**Ghrelin attenuates glucose-dependent ability of GLP-1 to increase cAMP, cytosolic  $\text{Ca}^{2+}$  and insulin release in islet beta cells**

**B. Damdindorj**<sup>1</sup>, K. Dezaki<sup>1</sup>, T. Kurashina<sup>1</sup>, R. Rita<sup>1</sup>, M. Kakei<sup>2</sup>, T. Yada<sup>1</sup>;

<sup>1</sup>Division of Integrative Physiology, Department of Physiology, Jichi Medical University, Tochigi, <sup>2</sup>First Department of Medicine, Saitama Medical Center, Jichi Medical University, Saitama, Japan.

**Background and aims:** A gastric hormone ghrelin and its receptor, growth hormone secretagogue-receptor (GHS-R), as well as ghrelin O-acyltransferase (GOAT), the enzyme that acylates the third serine residue of ghrelin, are all expressed in the pancreatic islets. Administration of GHS-R antagonists and GOAT inhibitors reportedly enhances plasma insulin responses and lowers glucose concentrations during glucose tolerance tests, indicating that ghrelin is a physiological insulinostatic hormone. We have reported that ghrelin stimulates pertussis toxin-sensitive  $\text{G}\alpha_{12}$ , an inhibitory subtype of GTP-binding proteins and attenuates cAMP signaling, thereby inhibiting glucose-induced increases in cytosolic  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) and insulin release in islet  $\beta$ -cells. This study aimed to clarify whether exogenous ghrelin counteracts and blockade of endogenous ghrelin enhances effects of glucagon-like peptide-1 (GLP-1), a physiological incretin hormone, on insulin release, cAMP and  $[\text{Ca}^{2+}]_i$  signaling in rat islet  $\beta$ -cells.

**Materials and methods:** Islets of Langerhans were isolated by collagenase digestion from male Wistar rats. Insulin release and cAMP production in isolated islets were measured under static incubation and determined by ELISA.  $[\text{Ca}^{2+}]_i$  in isolated islets and single  $\beta$ -cells was measured by fura-2 microfluorimetry.

**Results:** In rat isolated islets under static incubation, glucose (8.3 mM)-induced insulin release was potentiated by 10 nM GLP-1, and this potentiation was suppressed by ghrelin at 10 nM. The glucose (8.3 mM)-induced cAMP production in islets was enhanced by GLP-1, and this enhancement was blocked by ghrelin. In the presence of 8.3 mM glucose, GLP-1 and an adenylate cyclase activator forskolin evoked  $[\text{Ca}^{2+}]_i$  increases in single  $\beta$ -cells and they were significantly attenuated by ghrelin. Blockade of the action of islet-derived ghrelin by [D-lys<sup>3</sup>]-GHRP-6, a GHS-R antagonist, enhanced glucose-induced insulin release, cAMP production and  $[\text{Ca}^{2+}]_i$  increases in isolated islets, indicating that the insulinostatic action of endogenous islet-derived ghrelin. Moreover, [D-lys<sup>3</sup>]-GHRP-6 markedly elevated GLP-1-induced insulin release, cAMP production and  $[\text{Ca}^{2+}]_i$  increases in isolated islets.

**Conclusion:** The results indicate that both exogenous and endogenous ghrelin potently attenuates glucose-dependent insulinotropic actions of GLP-1 by suppressing cAMP-mediated  $[\text{Ca}^{2+}]_i$  signaling in islet  $\beta$ -cells, while ghrelin receptor antagonist potentiates the GLP-1-induced insulin release by elevating cAMP generation and  $[\text{Ca}^{2+}]_i$  increases. These findings indicate that interaction between ghrelin and GLP-1 plays an important role in physiological regulation of glucose-induced insulin release in islet  $\beta$ -cells, and suggest that ghrelin antagonism provides a novel strategy to treat type 2 diabetes with dysregulated insulin release.

### 406

**Knockout of connexin 36 (Cx36) blocks KCl-induced exchange of ATP with the medium and glucose-induced insulin secretion in isolated mouse islets**

**J. Tamarit-Rodriguez**<sup>1</sup>, J. Pizarro-Delgado<sup>1</sup>, L.C. Barrio<sup>2</sup>, R. Martín-del-Río<sup>2</sup>, M. Romero<sup>2</sup>, D. González-Nieto<sup>2</sup>, D.L. Paul<sup>3</sup>;

<sup>1</sup>Biochemistry, Complutense University, Madrid, Spain, <sup>2</sup>Research, Hospital Ramón y Cajal, Madrid, Spain, <sup>3</sup>Neurobiology, Harvard University, Boston, USA.

**Background and aims:** Rat islets loose amino acids and adenine nucleotides after KCl-depolarization even in the absence of extracellular  $\text{Ca}^{2+}$  discarding that a mechanism of exocytosis could be implicated. The leakage of intracellular metabolites is reversible, e.g., by adding extracellular ATP, and can be partially prevented by connexin/pannexin inhibitors mefloquine, flufenamic acid. To determine whether the adenine nucleotide exchange may be mediated by hemichannels of connexin-36 (Cx36), the principal connexin expressed

in pancreas islets, we have used constitutive Cx36-deficient mice (Cx36-KO) in our studies

**Materials and methods:** Islet ATP and ADP content were measured with the luciferin/luciferase method. Insulin release was radioimmunologically determined.

**Results:** 70 mM KCl-depolarization at 5 mM glucose (G5) decreased ATP content in wild ( $1.74 \pm 0.14$ ,  $n=11$  vs  $2.55 \pm 0.23$ ,  $n=11$  pmol/islet;  $p<0.008$ ) but not in KO-islets ( $3.82 \pm 0.33$ ,  $n=8$  vs  $3.65 \pm 0.21$ ,  $n=7$  pmol/islet; N.S.). However, basal (G5) ATP content in KO-islets was much higher than in wild controls at either G5 ( $3.82 \pm 0.33$ ,  $n=7$  vs  $2.55 \pm 0.23$ ,  $n=11$  pmol/islet;  $p<0.005$ ) or G20 ( $4.82 \pm 0.56$ ,  $n=6$  vs  $3.52 \pm 0.20$ ,  $n=10$  pmol/islet;  $p<0.04$ ). G20 increased, as expected, the intracellular content in both controls ( $3.52 \pm 0.20$ ,  $n=10$  vs  $2.55 \pm 0.23$ ,  $n=11$  pmol/islet;  $p<0.005$ ) and KO-islets ( $4.82 \pm 0.56$ ,  $n=6$  vs  $3.82 \pm 0.33$ ,  $n=7$ ; N.S.). As previously observed in normal rat islets, depolarization with 70 mM KCl allowed extracellular ATP (5mM) to increase its content in islets of wild type ( $4.49 \pm 0.58$ ,  $n=7$  vs  $1.74 \pm 0.14$ ,  $n=11$  pmol/islet;  $p<0.0001$ ) but not in KO-islets ( $4.11 \pm 0.63$ ,  $n=8$  vs  $3.65 \pm 0.21$ ,  $n=7$  pmol/islet; N.S.). The ATP/ADP ratio was measured in all the experiments and it was only increased by G20 in either wild ( $2.14 \pm 0.30$ ,  $n=9$  vs  $1.14 \pm 0.15$ ,  $n=9$ ;  $p<0.004$ ) or KO-islets ( $2.29 \pm 0.37$ ,  $n=5$  vs  $1.10 \pm 0.09$ ,  $n=7$ ;  $p<0.01$ ). Perfused wild type islets showed a biphasic insulin secretory response to a change of glucose concentration from 5 to 20 mM ( $22.8 \pm 6.0$ ,  $n=5$  vs  $85.8 \pm 21.0$ ,  $n=5$  ng insulin/30 min x 40 islet;  $p<0.02$ ). By contrast, KO-islets showed a significantly lower basal (G5) release of insulin than controls ( $7.5 \pm 1.5$ ,  $n=5$  vs  $22.8 \pm 6.0$ ,  $n=5$  ng insulin/30 min x 40 islet;  $p<0.05$ ) and it was only transiently and poorly stimulated by G20 ( $19.3 \pm 4.5$ ,  $n=5$  vs  $7.5 \pm 1.5$ ,  $n=5$  ng insulin/30 min x 40 islet;  $p<0.04$ ). Extracellular ATP (5 mM) stimulated a second phase of insulin secretion in control islets depolarized with 70 mM KCl ( $42.3 \pm 7.2$ ,  $n=4$  vs  $23.0 \pm 3.9$ ,  $n=5$  ng insulin/20 min x 40 islet;  $p<0.04$ ) but not in KO-islets ( $8.7 \pm 1.7$ ,  $n=6$  vs  $6.8 \pm 1.1$ ,  $n=6$  ng insulin/20 min x 40 islet; N.S.).

**Conclusion:** i) Deficiency of Cx36 in isolated mouse islets prevented the leakage of ATP to the extracellular medium and abolished the uptake of extracellular ATP, indicating that the transmembranal flux of ATP is mediated by Cx36 hemichannels. ii) Failure of Cx36-KO islets to increase insulin secretion in response to glucose highlights the importance of both Cx36 channels and hemichannels in the  $\beta$ -cells.

### Novel 2-way communication between liver and islets mediated by follistatin, insulin and glucagon

K. Bouzakri<sup>1</sup>, P. Plomgaard<sup>2,3</sup>, C. Brandt<sup>2</sup>, B.K. Pedersen<sup>2</sup>, P.A. Halban<sup>1</sup>;

<sup>1</sup>Department of Genetic Medicine and Development, CMU, Geneva, Switzerland, <sup>2</sup>Department of Infectious Diseases, Rigshospitalet, Centre of Inflammation and Metabolism, Copenhagen, Denmark, <sup>3</sup>Department of Clinical Biochemistry, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** Follistatin also known as activin-binding protein is a glycoprotein which binds and neutralizes several members of the TGF- $\beta$  superfamily, in particular myostatin and activin A. Recent studies have shown that plasma follistatin increases in response to exercise, or after prolonged starvation and the most likely origin is the liver. The aim was to explore the direct impact of follistatin on pancreatic islets and sorted beta-cells, as well as the impact of islet hormones on follistatin secretion.

**Materials and methods:** Primary rat beta-cells were used to explore the impact of 24 h exposure to follistatin (10 and 50 ng/mL) on apoptosis (TUNEL assay), proliferation (BrdU incorporation) and short-term insulin secretion (1h 2.8 mM glucose followed by 1h 16.7 mM glucose at the end of the 24h culture period). Human islets were exposed to 50ng/mL of follistatin for different timing up to 24h in order to explore in parallel insulin and glucagon secretion. Mice were injected intraperitoneally with glucagon (25  $\mu$ g/Kg body weight) and follistatin mRNA expression in the liver measured after 1h. Data are mean  $\pm$  SE.

**Results:** Beta-cells ( $n=4$ ) treated with follistatin for 24h showed a decrease in apoptosis when compared to untreated cells ( $0.17 \pm 0.06$  % and  $0.42 \pm 0.04$  % TUNEL positive cells for 10 and 50 ng/mL follistatin respectively vs.  $0.87 \pm 0.8$  % for control). Proliferation was increased when compared to untreated cells ( $7.73 \pm 0.37$  % and  $6.27 \pm 0.3$  % BrdU positive cells for 10 and 50 ng/mL follistatin respectively vs.  $4.0 \pm 0.17$  % for control). Interestingly, both 10 and 50 ng/mL follistatin increased basal insulin secretion respectively by  $2 \pm 0.1$  and  $2.2 \pm 0.12$ -fold, whereas glucose stimulated insulin secretion (GSIS) was decreased by  $39.2 \pm 0.56$  % (10ng/ml) and  $35.9 \pm 0.65$

% (50ng/ml) when compared to untreated cells. Human islets treated with 50ng/mL follistatin showed a decrease of basal insulin secretion ( $n=3$ ) during the first 6h of treatment and but an increase after 24h, whereas GSIS remain unchanged. Glucagon release ( $n=2$ ) at 16.7 mM glucose was decreased 4-fold after 1 and 2 h follistatin treatment but unchanged after 24h. There was no effect of follistatin on stimulated glucagon secretion (2.8 mM glucose) at any time of treatment. Mice injected with glucagon showed a 12.6-fold ( $p<0.05$ ) increase in liver follistatin mRNA 1 hour after administration compared to untreated mice.

**Conclusion:** Taken together our results show that follistatin can impact directly on beta-cell survival and proliferation as well as islet hormone secretion. Moreover, we show that glucagon can act on the liver to up regulated follistatin mRNA. These results suggest a novel 2-way axis of communication between islets and the liver, mediated by follistatin and two major islet hormones, insulin and glucagon.

### Green tea polyphenol epigallocatechin 3-gallate affects insulin secretion and AMPK in mouse and human islets through inhibition of glutamate dehydrogenase

S. Pournourmohammadi<sup>1</sup>, D. Bosco<sup>2</sup>, P. Maechler<sup>1</sup>;

<sup>1</sup>Department of Cell Physiology and Metabolism, <sup>2</sup>Department of Surgery, University of Geneva, Switzerland.

**Background and aims:** The mitochondrial enzyme glutamate dehydrogenase (GDH) participates to the control of insulin secretion and its absence in beta-cells limits the secretory response to glucose. Green tea polyphenol epigallocatechin 3-gallate (EGCG) has been shown to prevent progression to glucose intolerance in obese pre-diabetic mouse models. EGCG-mediated reduction of the secretory response could contribute to these effects and GDH is a putative target of EGCG. Here, we tested the specificity of EGCG for GDH using beta-cell specific GDH null mice ( $\beta$ Glut1<sup>-/-</sup>). Moreover, effects of EGCG on the secretory responses to different secretagogues were tested in human islets. Additionally, we investigated possible links between GDH activation and AMPK phosphorylation state.

**Materials and methods:** Mouse islets were isolated from wild type control mice (WT) and beta-cell specific GDH null mice ( $\beta$ Glut1<sup>-/-</sup>). Freshly isolated human islets were obtained from donors with the family's consent. The use of human islets for research was approved by the institutional ethic committee. The effects of 20 $\mu$ M EGCG were tested on insulin secretion in response to different insulin secretagogues (measured by RIA) and on AMPK phosphorylation state (immunoblotting).

**Results:** In WT mouse islets, EGCG reduced insulin secretion stimulated with 22.8mM glucose (-55%,  $p<0.05$ ). This inhibition was similar to the one conferred by the absence of GDH in  $\beta$ Glut1<sup>-/-</sup> islets (-52%,  $p<0.05$ ).  $\beta$ Glut1<sup>-/-</sup> islets were insensitive to EGCG as they did not exhibit further reduction of the secretory response, thereby indicating GDH-mediated action of EGCG. Addition of dimethyl-glutamate in the presence of EGCG fully restored the secretory response in WT islets. Insulin secretion stimulated by the GDH-dependent secretagogues glutamine plus BCH was markedly inhibited by EGCG (-67%,  $p<0.05$ ). In human islets, EGCG inhibited insulin secretion stimulated by 16.7mM glucose (-58%,  $p<0.05$ ) and glutamine plus BCH (-25%,  $p<0.05$ ). However, the secretory response to calcium-raising concentrations of KCl (30mM) was not changed by EGCG. Low glucose enhanced phosphorylated AMPK, an effect counteracted by incubation with GDH-dependent glutamine plus BCH, but reversed by further addition of EGCG.

**Conclusion:** The present data indicate that GDH is the main target of EGCG in mouse and human islets. The effects of EGCG on energy status demonstrated crosstalk between GDH and AMPK signalling.

## 409

### Is insulin secretion regulated by glucagon?

B. Svendsen, J. Pedersen, J.J. Holst;

The Novo Nordisk Foundation Center for Basic Metabolic Research, Department of Biomedical Sciences, Panum Institute, University of Copenhagen, Denmark.

**Background and aims:** Glucagon is secreted from the pancreatic alpha cells in the portal blood supply in response to hypoglycemia and acts as the major counter regulatory hormone to insulin. The intra-islet states that insulin reg-

ulates glucagon by suppression, but the role of glucagon in intraislet paracrine regulation is controversial. This study aimed to unravel intraislet paracrine functions of glucagon.

**Materials and methods:** In situ perfused mouse pancreases from wildtype mice as well as glucagon receptor knockout mice (M.Channon, New York) and diphtheria toxin mediated alpha cell knock-down transgenic mice infused with low (3.5 mM) and high (15.0 mM) glucose concentrations together with arginine, glucagon, insulin and somatostatin. Effluent concentrations of insulin, glucagon and somatostatin were measured.

**Results:** Infusion of arginine increased both glucagon, insulin and somatostatin secretion in control mice from a basal insulin level of  $6.6 \pm 2.4$  pM to a peak level of  $71.6 \pm 21.4$  (p=0.0108; n=7), basal glucagon level of  $14.3 \pm 4.1$  pM to peak level of  $49.9 \pm 7.1$  (p=0.0010), and basal somatostatin level of  $7.3 \pm 1.3$  pM to  $32.3 \pm 6.4$  (p=0.0183). 15 mM glucose increased insulin secretion ( $66.3 \pm 11.6$  pM) as compared to 3.5 mM glucose ( $4.5 \pm 1.9$  pM; p=0.0001) and somatostatin (from  $7.3 \pm 1.3$  to  $29.0 \pm 8.7$  pM). Glucagon receptor knock-out mice had dramatically increased secretion of glucagon ( $AUC_{0-65 \text{ min}}$ :  $8409 \text{ pM} \cdot \text{min}$ ) compared to controls ( $1489 \pm 119.3 \text{ pM} \cdot \text{min}$ ; p<0.0001) and decreased levels of insulin. Infusion of glucagon in control mice dramatically increased insulin secretion ( $AUC_{0-65 \text{ min}}$ :  $9620 \pm 119.5 \text{ pM} \cdot \text{min}$ ) as compared to controls ( $AUC_{0-65 \text{ min}}$ :  $279 \pm 548.7 \text{ pM} \cdot \text{min}$ ; p=0.001). Diphtheria toxin destroyed 95% of the alpha cells as indicated by a reduction in pancreas glucagon content of  $57 \pm 7.8$  pmol/g compared to a normal content of 500–600 pmol/g. Furthermore, the perfused pancreas showed no glucagon response to arginine after diphtheria toxin, and reduced insulin secretion ( $AUC_{0-65 \text{ min}}$ :  $1653 \pm 193.8$ ; p=0.04; n=7) vs. controls. Glucose stimulated insulin secretion was similar in control and alpha cell knockdown mice, arginine stimulation was abolished in knock-down.

**Conclusion:** Our findings suggest that alpha cells control insulin secretion rather than the opposite. Infusion of glucagon increased insulin secretion, while insulin secretion was decreased in glucagon receptor knockout mice and mice with an alpha cell knock-down. This is in keeping with recent discoveries regarding (human) islet microvasculature, showing beta cells covered by alpha cells receiving the blood supply. In rat perfusions performed in the lab, insulin at  $10^{-7}$  M was without effect on glucagon. Arginine stimulation of insulin depends critically on paracrine glucagon.

## 410

### ICA512 luminal domain: unravelling its role in insulinoma and pancreatic beta cells

J.M. Torkko<sup>1</sup>, A. Müller<sup>1</sup>, R. Dirksen<sup>1</sup>, M.E. Primo<sup>2</sup>, L. Sosa<sup>2</sup>, A. Altkrüger<sup>1</sup>, C. Münster<sup>1</sup>, D. Richter<sup>1</sup>, A. Friedrich<sup>1</sup>, M. Sica<sup>3</sup>, M. Ermácora<sup>4</sup>, M. Solimena<sup>4</sup>;

<sup>1</sup>Molecular Diabetology, Paul Langerhans Institute Dresden, Germany, <sup>2</sup>Consejo Nacional de Investigaciones Científicas y Técnicas (Conicet), University of Buenos Aires, Argentina, <sup>3</sup>Consejo Nacional de Investigaciones Científicas y Técnicas (Conicet), University of Quilmes, Buenos Aires, Argentina, <sup>4</sup>Consejo Nacional de Investigaciones Científicas y Técnicas, University of Quilmes, Buenos Aires, Argentina.

**Background and aims:** ICA512/IA-2/RPTPN is a catalytically inactive receptor tyrosine phosphatase enriched in the membrane of insulin secretory granules of pancreatic beta cells. Studies in insulinoma cells indicated that calpain-mediated cleavage of its cytoplasmic tail upon granule exocytosis gives origin to a retrograde signal that allows beta cells to adjust the biogenesis of granules to their consumption. Structural studies have shown that its mature ectodomain (ME ICA512), as adhesive mucins, contains a SEA domain-like fold and displays self-proteolytic activity in vitro. Here we investigated further the properties of the ICA512 luminal/extracellular domain.

**Materials and methods:** ICA512 expression was investigated by immunoblotting and immunocytochemistry of the cells, expressing various tagged ICA512 variants and also applying the extracellular region specific antibodies in the analyses.

**Results:** We show that RESP-18 homology domain is responsible for the sorting of ICA512 into granules. Accordingly, an ICA512 mutant lacking the entire luminal domain, except for ME ICA512, is constitutively delivered to the cell surface of insulinoma INS-1 cells. Strikingly, however, this mutant is not cleaved by calpain upon glucose stimulation. Moreover, we found that the N-terminal extracellular luminal domain and the membrane integral part ME ICA512 are subject to proteolysis during the maturation of insulin secretory granules.

**Conclusion:** Hence, an intriguing scenario is that proper sorting of ICA512 into granules and processing of its luminal domain are required for calpain-induced cleavage of its intracellular region, and thus its retrograde signaling.

### Analysis of mechanisms via which pure efaroxan enantiomers increase insulin secretion from perfused mouse islets

K. Stadlbauer<sup>1</sup>, Z. Lehner<sup>1</sup>, I. Rustenbeck<sup>2</sup>, A. Fenzl<sup>1</sup>, V.A.M. de Cillia<sup>1</sup>, D. Gruber<sup>1</sup>, A. Luger<sup>1</sup>, C. Fürnsinn<sup>1</sup>;

<sup>1</sup>Dept. Med. III, Div. Endocrinol. Metab., Medical University of Vienna, Austria, <sup>2</sup>Institute of Pharmacology and Toxicology, University of Braunschweig, Germany.

**Background and aims:** Several mechanisms of action have been implicated in the direct stimulation of insulin release from pancreatic islets by imidazoline compounds, which includes antagonism at  $\alpha 2A$ -adrenoceptors, closing of KATP-channels, and others. For a long period, research efforts have focused on non-adrenergic pathways. By comparison of purified enantiomers of the imidazoline efaroxan, the present study aimed to shed more light on the relative roles of the various mechanisms.

**Materials and methods:** Isolated islets of Langerhans from C57BL mice were perfused with buffers supplemented or not with inhibitors of insulin release that oppose mechanisms putatively addressed by imidazolines: 250  $\mu$ M of the KATP-channel opener diazoxide, or 1  $\mu$ M of the  $\alpha 2$ -adrenoceptor agonist UK14,304. The effects of concomitant exposure to efaroxan enantiomers (>99% ee) or to other drugs on the rates of insulin release were determined. All data in the abstract give pg cumulative insulin released per islet during 30 min of stimulation with 20 mM glucose.

**Results:** At the employed concentrations, both inhibitors almost completely blocked insulin release (vehicle,  $206 \pm 30$ , vs 1  $\mu$ M UK14,304,  $18 \pm 6$ ; vs 250  $\mu$ M diazoxide,  $15 \pm 6$ ; p<0.002 each vs vehicle). Secretion kinetics differed between the individual  $\alpha 2A$ -antagonists, but cumulative insulin release in response to established  $\alpha 2$ -antagonists supported our basic assumption that a higher potency to counteract the  $\alpha 2A$ -agonist UK14,304 than diazoxide is associated with an  $\alpha 2A$ -antagonistic mechanism of action (25  $\mu$ M yohimbine, antagonist without imidazoline structure: under UK,  $174 \pm 26$ , vs under Dia,  $68 \pm 18$ , p<0.02; 10  $\mu$ M phentolamine, antagonist with imidazoline structure: under UK,  $286 \pm 20$ , vs under Dia,  $62 \pm 5$ , p<0.005). High concentrations of the two enantiomers of efaroxan triggered similar responses in the presence of diazoxide [(+)-efaroxan: 100  $\mu$ M,  $170 \pm 6$ , p<0.001; 250  $\mu$ M,  $500 \pm 82$ , p<0.005; (-)-efaroxan: 100  $\mu$ M,  $155 \pm 32$ , p<0.05; 250  $\mu$ M,  $576 \pm 32$ , p<0.02; p values vs. diazoxide alone; no significant difference for comparison of enantiomers]. At variance to this, inhibition of insulin release by UK14,304 was counteracted by 100-fold lower concentrations of (+)-efaroxan than (-)-efaroxan [(+)-efaroxan: 0.25  $\mu$ M,  $38 \pm 16$ , ns; 2.5  $\mu$ M,  $265 \pm 26$ , p<0.001; 25  $\mu$ M,  $576 \pm 92$ , p<0.001; (-)-efaroxan: 25  $\mu$ M,  $34 \pm 16$ , ns; 250  $\mu$ M,  $559 \pm 104$ , p<0.02; p values vs. UK14,304 alone]. The latter finding is in accordance with the previously raised contention that the  $\alpha 2A$ -antagonistic activity of efaroxan is inherent to the (+)-enantiomer, which was further supported by binding data (IC<sub>50</sub> on  $\alpha 2A$ -adrenoceptors: (+)-efaroxan: 10 nM; (-)-efaroxan: 2.6  $\mu$ M).

**Conclusion:** In contrast to previous reports describing a distinct superiority of (-)-efaroxan under diazoxide, our results suggest similar potencies of the two enantiomers in the absence of adrenergic stimulation. However, the (+)-enantiomer carries a manifold higher potency than the (-)-enantiomer to counteract inhibition of insulin release by an  $\alpha 2$ -agonist. The observed superior potency at  $\alpha 2A$ -receptors vs. KATP-channels or other targets may have been underestimated in studies done without adrenergic stimulation.

## 412

### Mathematical model of glucose and amino acid induced toxicity in pancreatic beta cells

M. Salvucci<sup>1</sup>, L. Brennan<sup>2</sup>, Z. Neufeld<sup>3,4</sup>, P. Newsholme<sup>1,5</sup>;

<sup>1</sup>School of Biomolecular and Biomedical Science, University College Dublin, Ireland, <sup>2</sup>School of Agriculture and Food Science, University College Dublin, Ireland, <sup>3</sup>Complex & Adaptive Systems Laboratory, University College Dublin, Ireland, <sup>4</sup>School of Mathematics and Physics, University of Queensland, Brisbane, Australia, <sup>5</sup>School of Biomedical Sciences, Curtin University, Perth, Australia.

**Background and aims:** Glucose and the amino acid alanine are both known to acutely stimulate insulin secretion. However, there is substantial evidence that chronic exposure to high nutrient levels promotes impairment of  $\beta$ -cells function, contributing to the development of type 2 diabetes (T2DM). The objective of this study was to combine mathematical modelling with experimental work to elucidate mechanisms of high nutrient concentration dependent toxicity.

**Materials and methods:** The effects of 24 h exposure to either high glucose (HG, 30 mmol/l) or high alanine (HA, 10 mmol/l) with respect to control (CTRL, 11.1 mmol/l glucose) were investigated using a clonal rat insulin secreting cell line (BRIN-BD11). An ordinary differential equations based simplified kinetic model of core mitochondrial metabolic processes leading to ATP production (TCA cycle, alanine-specific reactions, respiratory chain, ATPase and proton leak) was built and numerically simulated in MATLAB.

**Results:** Both HG and HA chronic exposure resulted in no significant loss of cellular viability respect to CTRL. However, both treatments considerably reduced chronic insulin secretion from a control value of  $40.9 \pm 12.3$  ng/mg protein/24 h to  $35.8 \pm 9.7$  ng/mg protein/24 h for HG and  $27.3 \pm 8.3$  ( $P < 0.01$ ) for HA. Acute stimulation (20 min) with 16.7 mmol/l glucose plus 10 mmol/l alanine following HG or HA incubation also resulted in a significant reduction of insulin secretion compared with CTRL by 22 % ( $P < 0.05$ ) and 46 % ( $P < 0.01$ ) respectively. However, acute insulin secretion induced by 10 mmol/l alanine following HG culture and by 16.7 mmol/l glucose following HA exposure were found unaffected, suggesting that a selective desensitization. Moreover, KCl-induced insulin secretion was unaffected by either treatment. 24 h exposure to either HG or HA led to a marked decrease in ATP production from a CTRL value of  $2.67 \pm 0.91$  nmol/mg protein/24 h to  $2.32 \pm 1.33$  nmol/mg protein/24 h and  $1.12 \pm 0.15$  nmol/mg protein/24 h ( $P < 0.01$ ), respectively. Mathematical modelling was employed to identify key metabolic reactions whose alteration could minimize ATP production. Simulations indicated the enzymatic activities of lactate dehydrogenase (LDH), glutamate dehydrogenase (GDH), alanine amino-transferase (ALT) and aspartate amino-transferase (AST) as potential candidates. Following long term exposure to either HG or HA, LDH activity exhibited a 2.34 fold increase ( $P < 0.001$ ) and 1.59 fold increase ( $P < 0.01$ ), respectively. However, prolonged culture in HG or HA diminished AST activity by 57.33 % ( $P < 0.01$ ) and 35.93 % ( $P < 0.01$ ), respectively. ALT activity was not significantly altered while GDH activity was significantly decreased by 36.17 % ( $P < 0.01$ ) following 24 h HA incubation.

**Conclusion:** Experimental data and model simulations combined suggest that high nutrient concentrations exert a detrimental effect on  $\beta$ -cell insulin secretion via mitochondrial metabolism adaptations. Simulations suggest that pyruvate dehydrogenase and pyruvate carboxylase activities may be markedly altered following HG or HA chronic exposure. Ongoing experimental work is being carried out to confirm predictions.

## 413

### $\text{Ca}^{2+}$ -dependent desensitisation of insulin secretion by strong potassium depolarisation

M. Belz, K. Hatlapatka, A. Paufler, K. Schumacher, M. Willenborg, I. Rustenbeck;  
University of Braunschweig, Germany.

**Background and aims:** Depolarization by a high  $\text{K}^+$  concentration is a widely used experimental tool to stimulate insulin secretion. However, prolonged exposure to high  $\text{K}^+$  concentrations may induce counterregulatory effects which lead to the inhibition of secretion. Here the effects occurring after the initial rise in secretion were investigated.

**Methods:** Insulin secretion was measured by perfusion of NMRI mouse islets and ELISA of the fractionated efflux. The free cytosolic  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) was measured by the Fura-technique, the plasma membrane potential by a standard patch-clamp technique using the perforated-patch configuration.

**Results:** After the initial peak a fast decline occurred followed by a slowly progressive decrease of secretion, which was the stronger the higher the initial peak was. At 40 mM KCl, but not at lower concentrations the decrease continued when the glucose concentration was raised from 5 to 10 mM, suggesting an inhibitory effect of the  $\text{K}^+$  depolarization. At the end of the glucose perfusion (min 120), e.g. the secretion rate in the presence of 22.5 mM  $\text{K}^+$  was significantly higher than in the presence of 40 mM  $\text{K}^+$ . When tolbutamide was added instead of raising the glucose concentration a complete inhibition down to prestimulatory values was observed within 60 min from the beginning of the depolarization by 40 mM  $\text{K}^+$ . Equimolar reduction of the NaCl concentration to preserve isoosmolarity enabled an increase of secretion in response to glucose. Unexpectedly, the same was true when the  $\text{Na}^+$ -reduced media were made hyperosmolar by choline chloride or mannitol. The insulinotropic effect of tolbutamide was not rescued by the compensatory reduction of NaCl. Since the effect of 10 mM glucose and tolbutamide on membrane potential and  $[\text{Ca}^{2+}]_i$  were both intact, this suggests a requirement

for activated energy metabolism to permit the rescue by the decreased NaCl concentration. The progressive inhibitory effects of  $\text{K}^+$  depolarization could not be explained by a loss of depolarizing strength or by a diminished  $[\text{Ca}^{2+}]_i$ . However the elevated chloride concentration of the medium could play a role in the inhibition by 40 mM KCl. Thus we created a depolarizing medium with 40 mM  $\text{K}^+$  but with an unchanged  $\text{Cl}^-$  concentration by using potassium citrate and potassium hydroxide which resulted in an attenuated inhibition of secretion. Interestingly under this condition the steady state  $[\text{Ca}^{2+}]_i$  elevation was much lower than the one induced by the use of 40 mM KCl, indicating a chelate complexation of  $\text{Ca}^{2+}$ . When we used EGTA as substitute of citrate as  $\text{Ca}^{2+}$  buffer and 40 mM of KCl, the same phenomenon could be observed.

**Conclusion:** These data suggest that a strong, but not a moderate depolarisation by  $\text{K}^+$  induces a  $[\text{Ca}^{2+}]_i$ -dependent progressive desensitization of the secretory machinery. In contrast, the decline immediately following the initial peak of secretion may result from the inactivation of voltage-dependent  $\text{Ca}^{2+}$  channels.

### Pancreatic role for GLUT2 in human neonates evaluated by new variants identified in patients suffering from congenital hyperinsulinism

M. Le Gall<sup>1</sup>, A. Michau<sup>1</sup>, M. Keck<sup>1</sup>, S. Lhoste<sup>1</sup>, T. Grand<sup>1</sup>, A. Grosfeld<sup>1</sup>, P. Serradas<sup>1</sup>, J. Teulon<sup>1</sup>, P. De Lonlay<sup>2</sup>, E. Brot-Laroche<sup>1</sup>, A. Leturque<sup>1</sup>;  
<sup>1</sup>Inserm UMRS872, Paris, <sup>2</sup>Hôpital Necker Enfants Malades, Paris, France.

**Background and aims:** GLUT2 is a facilitative sugar transporter with low affinity and high capacity allowing large fluxes of sugar at physiological concentrations. GLUT2 is also a glucose receptor, detecting extracellular sugar and transducing a signal independent of glucose metabolism. The implication of GLUT2 in insulin secretion by pancreatic beta cells remains to be clarified in human although GLUT2 expression in beta cells was reported in neonates. Mutations in GLUT2 are associated with Fanconi-Bickel syndrome (FBS); patients suffer from glycogenosis and glucose homeostasis disorders improving with age. Neonates suffering from Congenital Hyperinsulinism syndrome (CHI) show severe hypoglycemia due to high insulin secretion. Mutations in genes coding for the pancreatic ATP-sensitive  $\text{K}^+$  channel are responsible for 50% of CHI, thus mutations in other genes are explored. Our hypothesis is that constitutive activation of human GLUT2 functions could be consistent with CHI syndrome. The aim of this study was thus to evaluate the role of GLUT2 in human neonate pancreatic function investigating impact of hGLUT2 natural variants on insulin secretion.

**Materials and methods:** We generated, by site-directed mutagenesis, a panel of 9 hGLUT2 natural variants to test their biological activity. We produced 4 single-point mutations suspected to abolish sugar transport, identified in FBS patients, and 3 single-point mutations as putative activating mutations identified in CHI patients. 2 single nucleotide polymorphisms (SNP) associated with diabetes or sugar-preference were also analyzed. Expression and cellular location of corresponding GLUT2 proteins were evaluated by western-blot and immunofluorescence. GLUT2-transporter kinetic parameters were calculated by measuring the uptake of radio-labeled 2-deoxy-D-glucose (2DOG) in *Xenopus* oocytes. GLUT2-receptor function was assessed by measuring glucose-sensitive gene mRNA accumulation in mhAT3F hepatoma cells. Impact on insulin secretion was assayed in insulin-secreting Min6 cells.

**Results:** The SNPs P68L and T110I did not modify GLUT2 transport activity, whereas the 4 FBS-associated mutations conducted to loss of GLUT2 function, due to altered location for G20D and S242R or lack of transport activity for P417L and W444R. Conversely, CHI-associated GLUT2 variants transported 2DOG and displayed modest alterations of kinetic parameters. Interestingly, G20S and L368P CHI variants stimulated insulin secretion by Min6 cells even in absence of glucose. This disqualified increased sugar transport as the single signaling event, and suggested that activation of receptor function of hGLUT2 may be in part responsible for the increased insulin secretion. Accordingly, L368P CHI variant displayed constitutive activation of GLUT2 receptor function since glucose-sensitive gene mRNA remained constantly high. In a pancreas biopsy of CHI a neonate, hGLUT2 was detected in insulin positive cells.

**Conclusion:** With this work, we involve human GLUT2 as an actor in insulin secretion process not only through its transporter- but also through its receptor-function in neonates. Activating mutations of GLUT2 can increase insulin secretion even in absence of glucose, we propose GLUT2 as a candidate gene to be sequenced in CHI patients.

### The conditional inactivation of Arx in pancreatic alpha cells

M. Courtney<sup>1,2</sup>, E. Gjernes<sup>1,2</sup>, C. Ravaud<sup>1,2</sup>, N. Druelle<sup>1,2</sup>, B. Faurite<sup>1,2</sup>, P. Collombat<sup>1,2</sup>;

<sup>1</sup>Université de Nice-Sophia Antipolis, Nice, <sup>2</sup>Inserm U1091, Diabetes Genetics Team, Nice, France.

**Background and aims:** The understanding and elucidation of the genetic determinants underlying pancreatic development may potentially aid the design of cell replacement therapies to treat type 1 diabetes mellitus. In this context, we have previously shown that endocrine fate specification largely rests on the interplay between two transcription factors, Pax4 and Arx. Indeed, if Pax4 predominates, the beta- and delta-cell lineages will be specified, whereas Arx will favour alpha-cell commitment. In addition, Arx and Pax4 were found to mutually inhibit each other's transcription through direct physical interaction with the pertinent promoter. We have previously demonstrated that the ectopic expression of Pax4 in pancreatic alpha-cells results in oversized islets primarily composed of functional insulin-expressing cells displaying most characteristics of true beta-cells. In addition, lineage-tracing experiments demonstrated a regeneration and conversion of glucagon-positive cells into insulin-expressing cells. Taking into account these data and the previous finding that Arx and Pax4 are mutually inhibitory, we sought to investigate whether the ectopic expression of Pax4 in glucagon-expressing cells and the ensuing alpha-to-beta cell conversion is a direct consequence of Pax4 expression or whether the selective inhibition of Arx expression in these glucagon-expressing cells is sufficient to induce such conversion.

**Methods and results:** Taking advantage of the Cre-LoxP system, we generated transgenic mice able to conditionally inactivate the expression of Arx in glucagon-expressing cells. These mice appear healthy and display normal basal glycaemic levels. Immunohistochemical analyses of double-transgenic mice revealed hypertrophic islets associated with a hyperplasia of insulin-expressing cells (up to 8 times more insulin-positive cells compared to their wild-type counterparts). Further characterisation revealed that these insulin-expressing cells displayed many of the classical  $\beta$ -cell markers and were functional when challenged with large doses of glucose. The introduction of ROSA26- $\beta$ -Gal to our system will allow us to perform lineage-tracing experiments to help us ascertain the origin of these beta-like cells. These results will be presented.

**Conclusion:** Our preliminary findings suggest that the conditional inactivation of the transcription factor Arx in glucagon-expressing cells results in hyperplastic islets filled with  $\beta$ -like cells. Should the inhibition of Arx activities be sufficient to induce the conversion of glucagon-producing cells into beta-like cell, this factor would represent a target of choice for therapies aiming at regenerating beta-cells in vivo.

### Role of aldehyde dehydrogenase 1 (ALDH1) activity in the developing human pancreas

J. Li, M. Wong, W. Rajan, Z.C. Feng, R. Wang;

Physiology & Pharmacology, Children's Research Institute, the University of Western Ontario, London, Canada.

**Background and aims:** Understanding the nature of islet progenitor cells and the signals that regulate neogenic activity is essential to precede any application of stem cell and islet biology for cell replacement therapies for the treatment of diabetes. ALDH1, a marker for normal and malignant human stem cells, regulates the conversion of retinaldehydes to retinoic acids (RA). However, data on the expression and functional role of ALDH1 in the developing human pancreas is limited. The aim of the present study is to characterize the ALDH1 expression patterns and functional role during islet cell differentiation in the developing human pancreas.

**Materials and methods:** Expression of ALDH1 and downstream signaling molecules in the developing human (8–21 week fetal age) pancreas were examined using microarray, quantitative RT-PCR, western blotting, immunohistological and cell sorting approaches. Human fetal islet epithelial cell clusters isolated from 15–18 weeks were cultured and treated with ALDH1

inhibitor, diethylaminobenzaldehyde (DEAB) and/or retinoic acid receptor agonists (e.g. all-trans-retinoic acid [ATRA]) for up to 5 days.

**Results:** A significant change in ALDH1 expression and ALDH-regulated RA signaling molecules was observed in the developing human pancreas. ALDH1 expression was localized to ductal cells and newly formed endocrine cells (glucagon+ and insulin+), and was frequently co-localized with key transcription factors (e.g. PDX1, SOX9 and NGN3) as well as stem cell surface markers (e.g. c-Kit) during islet cell differentiation. A significant increase ALDH1 expression in SOX9+ and NGN3+ cells was observed at 20–21 week of fetal age ( $p < 0.05$ ), however, a high level of ALDH1 colocalized with insulin observed early in development was significantly reduced as development progressed ( $p < 0.05$ ). Inhibition of ALDH1 using DEAB resulted in reduced endocrine cell differentiation together with a significant increase in cell apoptosis ( $p < 0.01$ ). Furthermore, these effects of DEAB on human islet-epithelial cell differentiation could be reversed by the co-treatment of the ATRA. In addition, the ATRA effect on islet differentiation was dose-dependent, suggesting that the ability of ALDH1 to generate retinoic acids is important in regulating islet cell differentiation.

**Conclusion:** Our findings indicate that ALDH1+ cells could represent precursor cells in the developing human pancreas and inhibition of its activity and retinoid signaling could impart human fetal islet cell differentiation and survival.

### Potential involvement of interleukin-6 in pancreatic alpha cell ontogeny

J. De Toro-Martín<sup>1</sup>, E. Fernández-Millán<sup>1,2</sup>, E. Lizárraga-Mollinedo<sup>1,2</sup>, F. Escrivá<sup>1,2</sup>, C. Álvarez<sup>1,2</sup>;

<sup>1</sup>Bioq. y Biol. Mol. II, Facultad de Farmacia, UCM, Madrid, <sup>2</sup>Ciberdem, ISCIII, Madrid, Spain.

**Background and aims:** The control of glucose homeostasis by the islets of Langerhans depends mainly on the coordinated secretion of glucagon and insulin by alpha- and beta-cells, respectively. The circulating levels of these hormones are partly determined by the number of these two endocrine cells types. During the early postnatal period, plasma glucagon concentration raises acutely. This condition is associated with an increase in alpha-cell mass but the trophic factors that regulate alpha-cell function and turnover during perinatal period have not been studied. Recently, pancreatic alpha-cells have been identified as a primary target of IL-6 actions regulating alpha-cell mass expansion and promoting glucagon expression and release. On the other hand, macrophage infiltrations are present in neonatal pancreas. All these premises have prompted us to investigate the physiological relevance of IL-6 to normal pancreatic alpha-cell development.

**Materials and methods:** The experiments were carried out in Wistar rats from fetal to adult age. Circulating glucagon and IL-6 were measured by RIA and ELISA, respectively. Histochemical and morphometric analyses were performed to quantify alpha-cell fraction, replication and apoptosis as well as the presence of CD68+ cells. Pancreatic IL-6 production was determined by RT-qPCR and immunostaining. To address whether IL-6 is affected in an animal model characterized by altered alpha-cell mass we used an under-nutrition rat model achieved by restricting maternal nutrition from the last third of gestation onwards to 35% of *ad libitum* intake.

**Results:** Alpha-cell fraction increased sharply after birth peaking on postnatal day 4 (PN4) and progressively decreasing to adult age. Similarly, pancreatic alpha-cell proliferation was as high as 3.5% at the end of gestation and 2.5% at the beginning of lactation but it diminished with time until values of 1.2% in adults. On the other hand alpha-cell apoptosis was low along the neonatal period but increased significantly at adult age. Serum glucagon levels paralleled the changes observed in the number of alpha-cells during development. However, circulating levels of IL-6 did not change with time suggesting no systemic effect on pancreas. In order to study the local production of IL-6, the mRNA expression of IL-6 in pancreas was analyzed. By PN4 IL-6 mRNA increased a 50% as compared to fetal age, then on PN14 the expression of IL-6 return to fetal values and finally, it decreased below fetal levels at the end of suckling time. Immunostaining of pancreatic sections localized the IL-6 within the islets mainly to the alpha-cells with no association to CD68+ cells. Undernourished (UN) rats showed decreased alpha-cell mass but normal islet architecture. Pancreas IL-6 mRNA expression was also reduced in UN rats and immunostaining of IL-6 showed delayed appearance of this cytokine within islets as compared to controls.

**Conclusion:** Birth represents an abrupt change from a high-carbohydrate to a high-fat and low-carbohydrate diet. This condition is associated with an

increment in alpha-cell mass. We found herein a transitory islet-derived IL-6 to the neonatal rat pancreatic alpha-cell, which may be required for ensuring alpha-cell mass expansion during this period.

### Non-invasive monitoring of pancreas transduction and beta cell mass in vivo with viral vectors

M. Morro<sup>1,2</sup>, R. Lage<sup>1,2</sup>, A. Casellas<sup>1,2</sup>, V. Jimenez<sup>1,2</sup>, C. Mallol<sup>1,2</sup>, S. Marletta<sup>1</sup>, J. Teichenne<sup>1</sup>, X. Leon<sup>1,2</sup>, M. Molas<sup>1,2</sup>, F. Kreppel<sup>3</sup>, S. Kochanek<sup>3</sup>, F. Bosch<sup>1,2</sup>, E. Ayuso<sup>1,2</sup>;

<sup>1</sup>Center of Animal Biotechnology and Gene Therapy and Department of Biochemistry and Molecular Biology, Universitat Autònoma de Barcelona, Bellaterra, Spain, <sup>2</sup>CIBER de Diabetes y Enfermedades Metabólicas Asociadas (CIBERDEM), Barcelona, Spain, <sup>3</sup>Department of Gene Therapy, University of Ulm, Germany.

**Background and aims:** The determination of  $\beta$ -cell mass in living mice is an important limitation in assessing the efficacy of those diabetes therapies aimed at protecting or regenerating insulin-producing cells. A non-invasive method that allowed the measurement, with high accuracy, of the  $\beta$ -cell mass over a period of time would greatly benefit diabetes research. Secretable alkaline phosphatase (seAP) is an attractive gene marker for non-invasive monitoring since it is secreted to the bloodstream, it is not immunogenic in mice, and detection by luminometric methods is highly sensitive. Serum values of seAP are directly correlated to  $\beta$ -cell mass when this gene is expressed under the control of Pdx-1 promoter in transgenic mice. We and others have shown that exocrine and endocrine pancreas can be genetically manipulated with adeno-associated and adenoviral vectors. Here, we aimed to use viral vectors expressing seAP to monitor pancreas transduction over time and to correlate seAP levels with  $\beta$ -cell mass.

**Materials and methods:** We have generated AAV9 and helper-dependent adenoviral (HD-Ad) vectors expressing the secretable Alkaline Phosphatase (seAP) under the control of the insulin (ins) and elastase (ela) promoter. These vectors were injected intraductally to healthy or diabetic mice.

**Results:** We demonstrate that intraductal delivery of AAV9-Ins-seAP and AAV9-ela-seAP vectors resulted in long term (>6 months) detection of seAP in the serum of healthy mice. Importantly, when AAV9-Ins-seAP vectors were administered to diabetic mice, seAP levels were almost undetectable, correlating with the reduced  $\beta$ -cell mass of these animals. In addition to AAV, HD-Ad are also promising tools for gene transfer since they can accommodate large transgenes and mediate long-term expression in animal models. For the first time, we demonstrate here that intraductal delivery of HD-Ad (Ins-seAP) vectors to healthy mice resulted in persistent (>5 months) circulating levels of seAP, indicating long-term transduction of  $\beta$ -cells.

**Conclusion:** We have shown that seAP is a useful transgene for non-invasive monitoring of pancreas transduction and viral vectors expressing seAP could be used to monitor changes in  $\beta$ -cell mass in mice

### Highly efficient pancreatic mouse islets due to activating glucokinase gene mutations: lessons from human models

F. Martin<sup>1</sup>, M. Navarro<sup>1</sup>, R. Araujo<sup>1</sup>, C. Vazquez<sup>2</sup>, E. Baixeras<sup>2</sup>, M. Repice<sup>2</sup>, A. Izarra<sup>3</sup>, N. Rodriguez<sup>2</sup>, J. Dominguez-Bendala<sup>4</sup>, A. Bernad<sup>3</sup>, A. Cuesta<sup>2</sup>;

<sup>1</sup>CABIMER-CIBERDEM, Seville, Spain, <sup>2</sup>Fundacion IMABIS, Malaga, Spain, <sup>3</sup>CNIC, Madrid, Spain, <sup>4</sup>Diabetes Research Institute, Miami, USA.

**Background and aims:** Humans affected with severe neonatal hypoglycemia due to GCK activating mutation (GCK-Hypoglycemia) present structurally well formed and very large islets,  $\beta$ -cell proliferation and some degree of apoptosis. In an affected patient reported, after a 98% pancreatectomy, the approximately 20,000 islets left, allowed the patient to live a normal life without developing diabetes. This finding is the proof of concept that a supra-physiological activation of glucokinase leads, in humans, to what should be considered, “highly efficient pancreatic human islets”. This finding opens a new and fascinating door to explore novel approaches to cell therapy as a treatment of diabetes. Our aim is to “in vitro” replicate these phenomena as a novel approach to diabetes cell therapy.

**Materials and methods:** Mouse islets were infected using lentiviral technology with the empty vector (pRRL.cmv.ires.eGFP) (eGFP islets), the vector containing wild type GCK (pRRL.cmv.GCK-WT.ires.eGFP) (GCK-WT islets) and the activating GCK mutation V91L found in the patient (pRRL.cmv.GCK-V91L.ires.eGFP) (GCK-V91L islets). After 6 and 15 days of infection, GSIR at different glucose concentrations (1.1, 2.8, 4.2, 5.6, and 8.3 mmol/l),  $\beta$ -cell proliferation (BrdU incorporation and Ki67 expression) and apoptosis (TUNEL imaging assay) was studied.

**Results:** The infection efficiency was 93% (n= 8 infections). GSIR (6d after infection) was significantly higher ( $p<0.05$ ; n= 5 infections, 15 GSIR experiments) above 4.2 mmol/l glucose in GCK-V91L islets, as compared to the rest of groups. Moreover, GCK-V91L islets started GSIR at lower glucose concentrations (4.2 mmol/l). After 15d of infection, GSIR was significantly higher ( $p<0.01$ ; n= 3 infections, 12 GSIR experiments) at all glucose concentrations in GCK-V91L islets. BrdU incorporation (15d after infection) was 6.8 fold higher (n= 3 infections, 60 islets analyzed) in GCK-V91L islets than in non-infected control and eGFP islets, and 5.1 fold higher (n= 3 infections, 60 islets analyzed) when compared with GCK-WT islets. Ki67 positive cells (15d after infection) were significantly higher ( $p<0.05$ ; n= 2 infections, 60 islets analyzed) in GCK-V91L islets as compared with the rest of groups. Apoptosis (15 d after infection) was significantly higher ( $p<0.05$ ; n= 2 infections, 28 islets analyzed) in GCK-V91L islets versus rest of groups.

**Conclusion:** We have been able to replicate “in vitro” the highly efficient islets described in the patient with severe neonatal GCK-Hypoglycemia. These islets could be used as a new tool, for diabetes cell therapy, to overcome the shortage of islets due to insufficient donors and problems in islet isolation.

### Accelerating the in vivo maturation of macro-encapsulated human embryonic stem cell derived-pancreatic progenitor cells by manipulating NKX6.1 expression in culture

J.E. Bruin<sup>1</sup>, J.K. Fox<sup>1</sup>, K. Narayan<sup>2</sup>, J. Xu<sup>2</sup>, A. Rezanian<sup>2</sup>, T.J. Kieffer<sup>1</sup>;

<sup>1</sup>Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada, <sup>2</sup>BetaLogics Venture, Janssen Research & Development, Raritan, USA.

**Background and aims:** Human embryonic stem cells (hESCs) are considered a potential alternative to cadaveric islets as a source of transplantable cells for treating patients with diabetes. We previously described a 4-stage, 14-day protocol that efficiently differentiated hESCs *in vitro* into a highly enriched pancreatic progenitor cell population, composed of mainly pancreatic endoderm cells (PDX1/NKX6.1 co-positive) and polyhormonal cells (insulin/glucagon co-positive). Following a lengthy maturation period (~30 weeks) in diabetic mice, these cells secreted human insulin in a meal- and glucose-dependent manner and were capable of treating pre-existing hyperglycemia. In the current study, we aimed to understand the respective roles of pancreatic endoderm and polyhormonal cells for *in vivo* maturation by manipulating the NKX6.1-expressing cell population in culture.

**Materials and methods:** Three different populations of pancreatic progenitor cells (expressing high, medium or low levels of NKX6.1) were generated *in vitro* with modified versions of our previously reported 14-day differentiation protocol and characterized by flow cytometry pre-transplant. Progenitor cells were transplanted subcutaneously within Theracyte<sup>TM</sup> encapsulation devices (5x10<sup>6</sup> cells/device) into SCID-beige mice with STZ-induced diabetes (n=8/group). Maturation of encapsulated cells was assessed by blood glucose tracking and meal/arginine challenges throughout the 5-month study.

**Results:** Prior to transplant all hESC-derived cell populations contained a high proportion of PDX1-positive cells (~85-90%), but were distinguished by their high (~80%), medium (~60%) or low (~25%) expression of NKX6.1. This was inversely proportional to the endocrine population (~13, 20 and 60% synaptophysin-positive cells in NKX6.1-high, -med and -low cultures, respectively). Endocrine cells in all groups were largely polyhormonal (insulin/glucagon co-positive) prior to transplant. Mice transplanted with NKX6.1-low cells remained hyperglycemic throughout the 5-month post-transplant period relative to the NKX6.1-med and -high groups. Overnight fasting human C-peptide levels were similar in all groups throughout the study, but the NKX6.1-high group displayed a significant increase in human C-peptide secretion following a meal challenge at 3 and 4 months post-transplant. Similarly, at 17 weeks arginine-stimulated human insulin secretion was only observed in the NKX6.1-high group; fasting glucagon levels were significantly higher in the NKX6.1-low group during this challenge.

**Conclusion:** hESC-derived cells containing relatively high proportions of NKX6.1-positive and low endocrine-positive cells matured more quickly into insulin-secreting cells with improved function compared to NKX6.1-med or -low cell populations *in vivo*. This accelerated maturation period may be beneficial for translating a progenitor cell-based therapy for clinical transplantation in patients with diabetes.

## 421

### Induction of gastrointestinal hormones in pancreatic islets of a mouse model of beta cell regeneration

K. Minami<sup>1</sup>, H. Kitanoya<sup>1</sup>, H. Takahashi<sup>1</sup>, S. Seino<sup>1,2</sup>;

<sup>1</sup>Division of Cellular and Molecular Medicine, <sup>2</sup>Division of Diabetes and Endocrinology, Kobe University Graduate School of Medicine, Japan.

**Background and aims:** We previously reported that pancreatic beta cells are spontaneously regenerated in mice expressing a dominant negative form of Kir6.2 gene specifically in the beta cells (Kir6.2G132S Tg mice). Although Tg mice exhibit severe hyperglycemia and marked loss of pancreatic beta cells at 4 weeks of age, the hyperglycemia is improved by concomitant improvement of pancreatic insulin content and beta cell mass at 25 weeks of age or older. However, the mechanism of regeneration of pancreatic beta cells in Kir6.2G132S Tg mice has remained unclear. We have addressed this issue by using comparative transcriptome analysis between pancreatic islets of Kir6.2G132S Tg mice and those of wild-type mice.

**Materials and methods:** Kir6.2G132S Tg mice (line M45) were originally generated in BDF1 mice and backcrossed to C57BL/6J mice. Changes in body weights, blood glucose levels, and serum insulin levels were measured. Pancreatic islets were obtained from mice at 4 (hyperglycemic state) and 25 weeks of age (improved glycemic state) by collagenase digestion and were subjected to GeneChip<sup>TM</sup> transcriptome analysis (n=3). Differential expression of genes was confirmed by quantitative real-time RT-PCR analysis. For immunohistochemistry, mice were perfused with phosphate-buffered paraformaldehyde to fix the tissues. Sections were prepared from the fixed tissues and subjected to immunostaining.

**Results:** At 4 weeks of age, the number of insulin-positive cells was reduced significantly in Kir6.2G132S Tg mice compared to wild-type mice. However, the number gradually increased with age: the Tg pancreas at 25 weeks of age was histologically indistinguishable from wild-type pancreas. We found that 255 and 309 genes were up-regulated (> 5-fold) in Kir6.2G132S Tg islets at 4 and 25 weeks of age, respectively. Expressions of 81 genes were increased at both 4 and 25 weeks of age. These include growth factors, gastrointestinal hormones, and transcription factors. In addition, 123 and 228 genes were down-regulated (> 5-fold) in Kir6.2G132S Tg islets at 4 and 25 weeks of age, respectively; 21 genes were decreased at both 4 and 25 weeks of age. Interestingly, more than 100-fold increase in gastrin gene expression was found in Kir6.2G132S Tg islets at 4 weeks of age. Indeed, immunoreactivity of gastrin was detected in the Tg islets. Up-regulation of gastrin gene was also evident at 25 weeks of age but the difference became small (9-fold). Furthermore, gene expression of another gastrointestinal hormone cholecystokinin (CCK) was increased in Kir6.2G132S Tg islets compared to wild-type islets (9-fold and 51-fold increase at 4 and 25 weeks, respectively). There was no significant difference in either CCK receptor (CCKAR) or gastrin receptor (CCKBR) expression between wild-type and the Tg islets as judged by GeneChip<sup>TM</sup> analysis.

**Conclusion:** Gastrin and CCK were up-regulated in Kir6.2G132S Tg islets in the course of recovery of glycemia and beta cell mass. Autocrine/paracrine signals of these gastrointestinal hormones may have roles in the regeneration of pancreatic beta cells in Tg mice.

## 422

### Fibrin-integrin support of beta cell differentiation, function and proliferation

M. Riopel<sup>1,2</sup>, J. Li<sup>1,3</sup>, W. Stuart<sup>1,2</sup>, R. Wang<sup>1,3</sup>;

<sup>1</sup>Children's Health Research Institute, <sup>2</sup>Pathology, Western University,

<sup>3</sup>Physiology and Pharmacology, Western University, London, Canada.

**Background and aims:** Extracellular matrix (ECM)-integrin stimulation has been shown to promote beta cell differentiation, function and proliferation. However, islets cultured on ECM proteins do not maintain islet archi-

tecture or long-term insulin expression and cannot form 3D scaffolds for *in vivo* transplantation. Fibrin is a provisional matrix protein that interacts with Arg-Gly-Asp-binding receptors, including  $\alpha 5\beta 1$  and  $\alpha V\beta$  integrins. It is used routinely as a biomaterial scaffold in surgery and tissue engineering, and was reported to support human and rat adult islet function. However, the role of fibrin-integrin interactions in support of beta cells has not been investigated. The objective of the current study is to assess the inter-relation between fibrin and integrins in promoting beta cell differentiation, function and proliferation.

**Materials and methods:** Isolated human fetal islet-epithelial cell clusters (18–21 weeks of age) and INS-1 cells were cultured with fibrin in 2D and 3D, and on tissue culture polystyrene (TCPS) for 1–4 weeks then analyzed by quantitative RT-PCR, western blot, immunofluorescence and ELISA techniques.

**Results:** The mRNA expression integrins  $\alpha V$  and  $\beta 3$  was significantly up-regulated along with PDX1, INS and GCG in human fetal islet-epithelial cells cultured with fibrin when compared to TCPS culture. This was associated with increased protein level of PDX1,  $\alpha V$  integrin and  $\beta 3$  integrin. Alongside, INS-1 cells cultured with fibrin showed increased mRNA expression of integrin receptors  $\beta 1$ ,  $\beta 3$  and  $\alpha V$ , with significantly increased expression of the *Ins1* gene ( $p < 0.001$ ) compared to control. Fibrin-culture of INS-1 cells also showed islet-like cluster formation. In addition, basal insulin secretion was significantly increased in INS-1 cells cultured on 2D fibrin ( $p < 0.01$ ), while glucose-stimulated insulin secretion was significantly higher in 3D fibrin culture ( $p < 0.05$ ) compared to controls. Also, fibrin promoted cell proliferation in human fetal islet-epithelial cell clusters and INS-1 cells after 1 week culture compared to TCPS culture ( $p < 0.01$ ). Furthermore, fibrin-cultured INS-1 cells showed preserved Pdx1 expression in nuclei with a significant decrease in apoptosis ( $p < 0.05$ ).

**Conclusion:** Fibrin culture of human fetal islet-epithelial cell clusters and INS-1 cells showed significantly increased cell differentiation, function and proliferation with decreased cell apoptosis. These improvements were corroborated with significantly increased  $\alpha V$ ,  $\beta 1$  and  $\beta 3$  integrin receptor expression. These results suggest that fibrin's ability to promote islet cell maintenance depends on up-regulation of key integrin receptors. Integrin blocking experiments will be conducted to understand the mechanisms behind fibrin's effects. Culturing pancreatic cells with fibrin may be beneficial in order to expand beta cell mass and differentiate precursors to beta cells to generate a cell source for use in cell-based therapies.

## 423

### Predominance of beta cell neogenesis in human at early stage of glucose intolerance

S. Yoneda, S. Uno, H. Iwahashi, A. Yoshikawa, J. Kozawa, K. Okita,

A. Imagawa, I. Shimomura;

Metabolic Medicine, Graduate School of Medicine, Osaka University, Japan.

**Background and aims:** Beta cell mass is regulated by a balance of beta cell neogenesis, replication and apoptosis. Recent studies have showed that beta cell mass decreased, beta-cell apoptosis increased and beta-cell neogenesis occurred in type 2 diabetes. However, it is unclear how beta-cell mass and the incidence of beta-cell neogenesis, replication and apoptosis change at each glucose tolerance stage in type 2 diabetes, especially in prediabetes.

**Materials and methods:** We classified 26 patients with a 75 g oral glucose tolerance test and their past history into 9 normal glucose tolerance (NGT), 9 impaired glucose tolerance (IGT), 8 newly-diagnosed diabetes mellitus (NDM) and 7 longstanding type 2 diabetic patients (LDM) before partial pancreatectomy, and quantitatively evaluated pancreatic tissues from those patients by immunohistochemical approach. The mean age of these patients composed of 13 males and 20 females was 68 years old, 17 patients had been diagnosed with pancreatic cancer, 4 with bile duct cancer, 9 with intraductal papillary mucinous neoplasm, 1 with carcinoma of the papilla of Vater, 1 with serous cyst adenoma, 1 with well-differentiated endocrine cancer. The mean diabetes duration of LDM group was 18.8 years.

**Results:** The relative beta cell area was 1.48 %, 1.07 %, 0.92 % (vs NGT,  $P = 0.003$ ) and 0.52 % (vs NGT,  $P < 0.001$ ) in NGT, IGT, NDM and LDM, respectively. The numbers of single beta cells and clusters, defined as single insulin-positive cell and a unit comprising three cells or fewer insulin-positive cells, both of which did not form part of larger islet structures, were 2.0, 3.9 (vs NGT,  $P = 0.031$ ), 4.0 (vs NGT,  $P = 0.016$ ), and 1.5 (/5 mm<sup>2</sup>), respectively. On the other hand, the mean areas of one islet excluding single beta cells and clusters were 11756  $\mu\text{m}^2$ , 12847  $\mu\text{m}^2$ , 11402  $\mu\text{m}^2$ , 11374  $\mu\text{m}^2$ , respectively, with no significant difference among the groups, indicating that the hypertrophy

of islet did not occur in each group. The percentage of the duct cells positive for insulin, indicating beta cell neogenesis, was 0.59 %, 0.96 % (vs NGT,  $P = 0.018$ ), 0.72 % and 0.26 %, respectively. The percentage of beta cells positive for somatostatin, indicating immature beta cells during neogenesis, was 0.58 %, 1.14 % (vs NGT,  $P < 0.001$ ), 1.24 % (vs NGT,  $P = 0.014$ ) and 0.36 %, respectively. The percentage of beta cells positive for glucagon, also indicating immature beta cells during neogenesis, was 0.48 %, 0.73 % (vs NGT,  $P = 0.030$ ), 0.86 % (vs NGT,  $P < 0.001$ ), and 0.34 %, respectively. The percentage of beta cells positive for Ki67, indicating beta-cell replication, was 0.07 %, 0.10 %, 0.12 % and 0.04 %, respectively, with no significant difference among the groups. The percentage of beta cells positive for TUNEL, indicating beta-cell apoptosis, was 0.02 %, 0.03 %, 0.06 % and 0.12 % (vs NGT,  $P = 0.011$ ), respectively.

**Conclusion:** The relative beta cell areas decreased and beta cell apoptosis increased in the development from NGT to IGT, NDM, LDM. Beta cell replication did not increase, but beta cell neogenesis increased in IGT and NDM compared with NGT, indicating that beta-cell neogenesis is more important than replication as mechanism of compensation for decrease of beta cell mass. LDM had lower incidence of beta cell neogenesis, suggesting that this mechanism does not work after the long duration of type 2 diabetes.

### Is the side population of the human pancreas a source for adult stem cells?

P. Augstein<sup>1,2</sup>, T. Loudovaris<sup>3</sup>, E.M. Bandala Sanchez<sup>2</sup>, G. Naselli<sup>2</sup>, L. Lee<sup>2</sup>, K. Rogers<sup>2</sup>, W.J. Hawthorne<sup>4</sup>, F. Vaillant<sup>2</sup>, P. Heinke<sup>1</sup>, L.C. Harrison<sup>2</sup>;

<sup>1</sup>Institute of Diabetes, Karlsburg, Germany, <sup>2</sup>The Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, <sup>3</sup>The St. Vincent's Institute of Medical Research, Melbourne, Australia, <sup>4</sup>Westmead Hospital, University of Sydney, Australia.

**Background and aims:** The 'side population' (SP) is characterized by the ability to efflux the fluorescent dye Hoechst 33342 and is visualized as a tail from the main population (non-SP) by UV excitation. In rodent models, the SP of several tissues including bone marrow and liver is enriched for adult stem cells. Our aim was to identify the SP and characterize its phenotype and colony-forming potential (CFP) in the adult human pancreas.

**Materials and methods:** Pancreata were obtained, with informed consent from next-of-kin, from heart beating, brain dead donors and processed by a modified Ricordi method of intraductal infusion and digestion with collagenase, followed by fractionation on a continuous Ficoll density gradient and a COBE cell processor. Non-islet pancreatic digest from 30 donors was cultured short-term and stained with Hoechst 33342 to identify the SP. For phenotyping, Hoechst-labeled cells were stained with antibodies to haematopoietic, mesenchymal and epithelial stem cell markers. Antibodies to islet (Hp1), acinar (Hpx2), large ductal (Hpd1) and all ductal (CA19-9) cells were used to identify the pancreatic cell type. Cells were analysed with a BD LSR II-W flow cytometer. Wilcoxon signed-rank test was used to test the level of statistical significance. CFP was evaluated in a 2D-assay with irradiated fibroblasts as feeder cells after sorting SP and non-SP cells in a BD FACSAria C.

**Results:** SP cells were detected in the non-endocrine digest of all donor pancreata and their proportion was independent of donor sex, age and BMI. A low proportion of SP and non-SP cells expressed the haematopoietic markers CD117 and CD45. The mesenchymal markers CD44 and CD29 were highly expressed on both SP and non-SP cells. Expression of CD166, CD90 and CD31 was similar on SP and non-SP cells. The proportion of non-SP cells expressing CD34 was higher than SP cells ( $p=0.034$ ). The epithelial marker EpCam was detected on nearly all SP and non-SP cells. Similarly, expression of CD24, CD49f and Trop-2 was similar on SP and non-SP cells. However, the proportion of cells expressing CD133 ( $p=0.001$ ) and CD26 ( $p=0.0001$ ) was increased in the SP. The islet cell surface antigen Hpi1 was detected at low frequency ( $p=0.281$ ) on SP and non-SP cells. Cells expressing the exocrine surface antigen Hpx2 were enriched in the non-SP ( $p=0.001$ ). However, the proportion of cells expressing the ductal markers Hpd1 ( $p=0.001$ ) and CA19-9 ( $p=0.008$ ) was increased in the SP. To evaluate CFP, SP and non-SP cells were sorted after exclusion of islet (HPi1-) and haematopoietic (CD45-, glycophorin-, CD31-) cells. After 2 weeks in culture, CFP in SP cells (0.29/100 cells) was greater than in non-SP cells (0.05/100 cells).

**Conclusion:** We confirm the presence of SP cells in the adult human pancreas and demonstrate for the first time that they are enriched for cells expressing the ductal marker CD133 and for CFP. These findings are consistent with the notion that SP cells are a reservoir of stem cells in the adult pancreas.

### Pancreatic duct glands - a stem cell niche in the pancreas?

B. Gier<sup>1</sup>, A.E. Butler<sup>1</sup>, A.V. Matveyenko<sup>1</sup>, D. Kirakossian<sup>1</sup>, S.M. Dry<sup>1</sup>, M.A. Atkinson<sup>2</sup>, P.C. Butler<sup>1</sup>;

<sup>1</sup>Medicine/ Endocrinology, David Geffen School of Medicine, Los Angeles,

<sup>2</sup>Pathology, University of Florida, Gainesville, USA.

**Background and aims:** It is unknown if there is a pancreatic tissue stem cell niche. The pancreatic duct gland (PDG) compartment has been proposed to have this role harbouring both exocrine duct like cells and a minority of endocrine cells. Tissue specific stem cells are typically anatomically crypt like, harbour cells expressing early developmental markers relevant to the organ of interest and have transit amplifying zones of cells with a capacity for in-

creased replication that is amplified under conditions of inflammation in the client organ. Acute tissue damage thus prompts tissue repair while chronic organ damage may induce dysplasia. We sought to further examine PDGs in humans and relevant rodent models to determine if these properties of pancreatic stem cell niche are met, and if they are induced to proliferation by beta cell apoptosis in type 2 diabetes (T2DM).

**Materials and methods:** PDGs were isolated by laser microdissection of frozen pancreatic sections from humans with T2DM, non diabetic controls and in rats. RNA was isolated from captured cells, and after RNA denaturation and reverse transcription, real-time quantitative PCR was performed to identify expression of genes of interest. Immunohistochemistry of fixed tissue was used to complement RNA expression studies. The frequency of PDG replication was assessed by Ki67 immunostaining.

**Results:** Expression markers and transit amplifying zone of a stem cell niche? PDGs in humans and rats express the developmental genes *Nestin* and *Hes-1* as well as early pancreatic progenitor markers such as *Sox-9* and *Pdx-1*. PDGs also express *Ngn3*, the transcription factor required to direct progenitor cells towards an endocrine lineage. Moreover, a subset of PDG cells express *Lgr5* and *Aldh*, both specific stem cell markers in stem cell crypts of ileum and colon. Also, consistent with a stem cell transit amplifying zone, PDGs (humans and rats) have zones of increased replication (Ki67) compared to the rest of the pancreas. *Activation by inflammation in client tissue compartment?* PDG replication is increased in humans with T2DM compared to non diabetic controls (2.1% vs 0.8%). To establish if this is prompted by beta cell apoptosis or the metabolic sequelae of beta cell failure we quantified PDG replication in the human IAPP transgenic rat model of type 2 diabetes (HIP rat) compared to wild type (WT) rats. PDG replication was increased (7.9% vs 4.3%) in HIP rats before the onset of hyperglycemia but coincident with increased beta cell apoptosis. Moreover, chronic glucose infusion induced hyperglycemia in WT rats did not increase PDG replication. *Cell types of client organ?* The majority of cells in PDGs (humans and rats) have an exocrine duct cell phenotype but a minority (~1%) are endocrine cells, expressing insulin and/or glucagon.

**Conclusion:** The PDG compartment of the pancreas bears the anatomic and cellular molecular expression profile of a tissue stem cell compartment. Moreover PDGs undergo proliferation in response to beta cell apoptosis, consistent with attempted regeneration. Since PDGs appear to provide new cells in proportion to the epithelia cell types in pancreas (~1% endocrine, ~99% exocrine), chronic stimulation of this cell stem cell niche by beta cell apoptosis may induce exocrine dysplasia rather than effective beta cell regeneration. This may provide an explanation for increased pancreatic dysplasia (chronic pancreatitis and pancreatic cancer) in T2DM.

### Involvement of heparan sulfate 6-O-sulfotransferase isoform-1 in the mouse beta cell proliferation during pregnancy

I. Takahashi, T. Sato, F. Sato, K. Ohashi, K. Nata;

Dept of Medical Biochemistry, Iwate Medical University, Yahaba, Japan.

**Background and aims:** Maternal pancreatic islet proliferation in pregnancy is one of the interesting phenomena for  $\beta$ -cell expansion in physiological conditions. However, the molecular mechanisms underlying these events are only partially understood. Heparan sulfate (HS) is linear polysaccharides consisting of repeating disaccharide unit backbone onto which is superimposed a complex pattern of modifications, most notably addition of sulfate groups. The produced polymorphic sulfated sequence motifs are responsible for binding to a variety of signaling molecules and modulating their biological functions. Recently, we found that HS is localized exclusively around  $\beta$ -cells in islets of adult mice and required for islet morphogenesis,  $\beta$ -cell proliferation and insulin secretion. Furthermore, we found that the sulfate groups of HS, in particular the 3-O-sulfate modification generated by HS 3-O-sulfotransferase isoform-1, are necessary for maintaining normal glucose-induced insulin secretion (GIIS). The aim of this study is to clarify the effect of the modification in HS including sulfation for  $\beta$ -cell function and proliferation during pregnancy.

**Materials and methods:** Islets of Langerhans from C57BL/6J female mice were isolated from non-pregnant and pregnant (gestational days 13.5 [G13.5]) mice. Quantitative RT-PCR was used for analyzing mRNA expression of HS synthesis and modification enzymes and components of several signaling pathways. Expression of HS 6-O-sulfotransferase isoform-1 (Hs6st1) was silenced and GIIS and cell proliferation were examined in MIN6, insulin-secreting mouse insulinoma cell line.

**Results:** The HS synthesis and modification enzymes, including Ext/Extl gene family, N-deacetylase/N-sulfotransferases, Glucuronyl C5-epimerase (Glce), Hs6st1 and HS 3-O-sulfotransferases were detected in islets and MIN6 cells. Among these genes, increase of expression of Glce, Hs6st1 and HS 3-O-sulfotransferase isoform-3B1 during pregnancy was detected (fold change 3- to 4-fold) by real-time PCR analysis of islets mRNA isolated from non-pregnant and pregnant mice at G13.5. Silencing of a Hs6st1, one of these upregulated enzymes, by RNA interference reduced MIN6 cell proliferation to 77% of control treatment ( $p < 0.001$ ). On the other hand, GIIS was unaffected in MIN6 with the RNA interference on Hs6st1. We determined by RT-PCR the expression pattern of the components of signaling pathways downstream of HS, especially these pathways affected by 6-O-sulfate modification: signaling pathway of fibroblast growth factor (Fgf), Notch, Hedgehog, Wnt and Transforming growth factor  $\beta$ . The mRNA levels of Fgf receptor (Fgfr1 and Fgfr2, the Fgf signaling components), were increased in Hs6st1 silenced MIN6 when compared to the control (1.7- and 1.3-fold, respectively).

**Conclusion:** Our data suggest that 6-O-sulfate groups modified by Hs6st1 play important role(s) in the adaptive  $\beta$ -cell proliferation during pregnancy. Our result also suggests Fgf signaling components including Fgfr1 and 2 may be involved in the signaling pathway in  $\beta$ -cell proliferation downstream of HS.

## 427

### Increased beta cell replication but impaired beta cell neogenesis and deficient beta cell mass expansion in response to 90% pancreatectomy and to gastrin treatment in aged rats

N. Tellez<sup>1,2</sup>, M. Vilaseca<sup>1,2</sup>, E. Montanya<sup>1,2</sup>;

<sup>1</sup>Lab. Diabetes and Experimental Endocrinology, IDIBELL-University of Barcelona, L'Hospitalet de Llobregat, <sup>2</sup>CIBERDEM, Barcelona, Spain.

**Background and aims:**  $\beta$ -cell replication reduction with age may preclude  $\beta$ -cell mass expansion in response to the increased metabolic demand. However, the adaptive stimulation of  $\beta$ -cell neogenesis in aged pancreas has not been explored. In a recent study we found that gastrin treatment stimulated  $\beta$ -cell neogenesis, increased  $\beta$ -cell mass and improved the metabolic outcome after subtotal pancreatectomy (Px) in young rats. The aim of our study was to investigate the  $\beta$ -cell regeneration potential of aged rats exposed to Px and gastrin. **Materials and methods:** 1 and 12 months old Wistar rats underwent 90%-Px and were treated from the day of surgery with [15Leu] gastrin-17 (150  $\mu$ g/kg  $\cdot$  12h, Px+G, n=13) or with vehicle (Px+V; n=13). A group of sham-operated rats treated with vehicle was included for each age (S+V; n=10). Pancreatic remnants were harvested on day 14 upon Px and  $\beta$  (insulin), acinar (amylase) cell mass (morphometry) and replication (BrdU) were determined. Beta cell size, beta cell apoptosis (TUNEL) and indirect signs of  $\beta$ -cell neogenesis (scattered extra-islet beta cells) were additionally evaluated.

**Results:** Ninety percent Px induced pancreas regeneration in both young and aged rats shown by the increased pancreas weight 14 days after Px (Young rats, S+V: 83 $\pm$ 4.9mg; Px+V: 119 $\pm$ 7.3mg;  $p < 0.05$ ; aged rats, S+V: 152 $\pm$ 9.35mg; Px+V: 212 $\pm$ 15.4mg;  $p < 0.05$ ). Consistent with previous results, Px young rats showed increased  $\beta$ -cell mass (S+V: 0.37 $\pm$ 0.04mg; Px+V: 0.79 $\pm$ 0.12mg;  $p < 0.05$ ), and neogenesis (S+V: 0.28 $\pm$ 0.02%; Px+V: 0.37 $\pm$ 0.04%;  $p < 0.05$ ) that were further enhanced by gastrin treatment ( $\beta$ -cell mass: 1.40 $\pm$ 0.18mg;  $p < 0.05$  vs Px+V;  $\beta$ -cell neogenesis: 0.54 $\pm$ 0.07%;  $p < 0.05$  vs Px+V). Moreover, Px+G rats showed improved metabolic evolution compared to Px+V (day 14: 109 $\pm$ 3.84 mg/dl vs 124 $\pm$ 5.76 mg/dl;  $p < 0.05$ ).  $\beta$ -cell replication and apoptosis were similar among groups and individual beta cell size was similarly increased in both Px groups. In aged rats, both Px groups developed hyperglycemia (day 14; Px+V: 275 $\pm$ 87.8 mg/dl, Px+G: 282 $\pm$ 82.9 mg/dl). Acinar and  $\beta$ -cell replication were stimulated upon Px (acinar cell replication: S+V: 0.10 $\pm$ 0.02%; Px+V: 1.12 $\pm$ 0.14%; Px+G: 0.9 $\pm$ 0.14%;  $p < 0.05$  S+V vs Px groups;  $\beta$ -cell replication: S+V: 0.03 $\pm$ 0.03%; Px+V: 0.53 $\pm$ 0.11%, Px+G: 0.78 $\pm$ 0.19%;  $p < 0.05$  S+V vs Px groups). Accordingly, acinar cell mass was increased in Px rats (S+V: 121 $\pm$ 8.8mg; Px+V: 175 $\pm$ 16.5mg; Px+G: 179 $\pm$ 9.6mg;  $p < 0.05$  S+V vs Px groups). However,  $\beta$ -cell mass was similar among groups (S+V: 1.8 $\pm$ 0.35mg, Px+V: 1.46 $\pm$ 0.36mg, Px+G: 1.45 $\pm$ 0.20mg), and  $\beta$ -cell neogenesis was not increased in Px aged rats (S+V: 0.27 $\pm$ 0.04%; Px+V: 0.27 $\pm$ 0.03%; Px+G: 0.23 $\pm$ 0.02%).

**Conclusion:** In aged rats, acinar cell regeneration was increased upon Px leading to acinar cell mass expansion. In contrast,  $\beta$ -cell mass expansion was impaired despite the increased  $\beta$ -cell replication.  $\beta$ -cell neogenesis, which was significantly stimulated in young rats, was impaired in response to Px and gastrin treatment in aged rats, suggesting that  $\beta$ -cell neogenesis plays a role on adult  $\beta$ -cell mass expansion.

**Neurotransmitters of the parasympathetic system regulate beta cell regeneration in 90% pancreatectomised rat**

A. Ilias, M. Alawieh, M. Ah Kioon, B. Portha, J. Movassat;  
University Paris Diderot/ CNRS, Paris, France.

**Background and aims:** Pancreatic beta cells retain the capacity to regenerate in the context of cell deficiency. To date, the regulation of beta cell regeneration by the neurotransmitters of the autonomous nervous system is poorly documented. Our aim was to decipher the individual role of the parasympathetic neurotransmitters: Acetylcholine and Gastrin Releasing Peptide (GRP) in the regulation of pancreatic beta cell regeneration following 90% pancreatectomy (Px) in adult rat.

**Materials and methods:** We developed an approach based on the specific inactivation of receptors of these neurotransmitters (Muscarinic M3 receptor for acetylcholine, GRP receptor) by the means of antisense morpholino oligonucleotides (As Mo). Immediately after 90% Px, a specific As Mo against each of the above receptors were injected within the remnant pancreas of a group of rats. Another group of rats was treated with non specific standard morpholino (Std) and served as control. 8h, 48h or 7days after surgery, animals were sacrificed and remnant pancreases were removed and processed for immunohistochemistry. Beta cell proliferation was assessed by BrdU incorporation method and the beta cell mass was evaluated by morphometry.

**Results:** Our data show that downregulation of M3 and GRP receptors dramatically reduced beta cell proliferation 48h after surgery. The beta cell mass measured at 48h and 7 days post-surgery was also significantly reduced at least partly due to the decreased beta cell proliferation.

**Conclusion:** In conclusion we reveal that among neurotransmitters of the parasympathetic nervous system, acetylcholine and GRP play a significant role in the regulation of the beta cell mass regeneration after 90% pancreatectomy.

## 429

**Rho-kinase and TGF- $\beta$ 1 inhibition delay dedifferentiation of pancreatic exocrine cells in culture**

K.R. Muir, M.J. Lima, K. Docherty;  
University of Aberdeen, UK.

**Background and aims:** A cell based therapy is seen by many as the best hope of a cure for type 1 diabetes mellitus. When placed in standard culture conditions pancreatic islets rapidly dedifferentiate to take on a mesenchymal stem cell phenotype losing the ability to produce insulin and other endocrine hormones. A similar process takes place with exocrine pancreatic cells losing amylase production after dedifferentiation. The exocrine fraction of the pancreas holds great potential in reprogramming towards beta cells due to plentiful supply and similarities in embryological development. Strategies for prevention of this dedifferentiation process may involve the targeting of selected cell signalling pathways. We propose that the inhibition of Rho kinase in combination with TGF $\beta$ 1 inhibition can slow down this process of epithelial to mesenchymal transition and lead to cells retaining epithelial morphology and function for longer in culture.

**Materials and methods:** An exocrine enriched pancreatic cell population left over from islet transplantation was used in the experiments. Immediately after arrival the cells were plated on 6 well plates at 175 000 clusters per well with RPMI medium + 10% fetal bovine serum and left for 48 hours to attach. At this point they were incubated with either a Rho Kinase inhibitor (Y27632), a TGF $\beta$ 1 inhibitor (SB431542), or a combination of both. The cells were harvested after 5 days and gene expression of endocrine, exocrine, epithelial and mesenchymal markers quantified by RTqPCR. These results were also compared to samples harvested at 48hours prior to treatment.

**Results:** Following treatment with both Y27632 and SB431542 expression of amylase showed a 334% increase compared to untreated control and 168% increase compared to baseline at 48 hours in culture. Insulin showed a 571% increase compared to control but a decrease of 69% compared to baseline. Glucagon expression was 535% higher than control and 4% lower than baseline. Epithelial marker E-cadherin showed a 29% increase compared to control and 12% increase compared to baseline. All these markers were elevated at a statistically significant level compared with untreated controls. The mesenchymal marker vimentin remained statistically unchanged throughout. A greater effect was seen when Y27632 and SB431542 were used in combination rather than individually.

**Conclusion:** The results suggest that the addition of Y27632 and SB431542 to exocrine enriched pancreatic cells in the initial stages of culture may slow down the epithelial to mesenchymal transition that rapidly ensues. This holds promise as maintaining an epithelial morphology may result in cells that are more amenable to reprogramming towards an endocrine lineage. Further work is required to determine whether these inhibitors have the potential to reverse fully dedifferentiated cells. If this is possible dedifferentiated cells could be expanded and later redifferentiated providing a near unlimited supply of exocrine material for reprogramming.

**Expression of IBCAP (intestine-derived beta cell augmenting promoter), an intestine specific secretory factor, induces insulin positive cells in the liver**

T. Yokoo<sup>1</sup>, K. Watanabe<sup>2</sup>, K. Tada-Iida<sup>2</sup>, H. Suzuki<sup>2</sup>, H. Shimano<sup>2</sup>, M. Kawakami<sup>3</sup>, N. Yamada<sup>2</sup>, Y. Okazaki<sup>1</sup>, H. Toyoshima<sup>1,3</sup>;

<sup>1</sup>Division of Functional Genomics & Systems Medicine, Research Center for Genomic Medicine, Saitama Medical University, Hidaka, <sup>2</sup>Department of Internal Medicine, Metabolism and Endocrinology, Faculty of Medicine, University of Tsukuba, <sup>3</sup>1st Department of Comprehensive Medicine, Saitama Medical Center, Jichi Medical University, Saitama, Japan.

**Background and aims:** IBCAP is an intestine-specific secretory protein with incretin-like activity, discovered in our laboratory. Adenoviral expression of IBCAP was shown to increase the amount of pancreatic  $\beta$ -cells, and improves the glycemic control of STZ-treated diabetic mice. Also, transgenic mice over-expressing IBCAP was demonstrated to have increased amount of pancreatic  $\beta$ -cells, whereas gene-knockouts of the factor resulted in a marked decrease of pancreatic islets. Our findings strongly suggested IBCAP as a major player in the control of the amount of pancreatic islets and  $\beta$ -cells. In the current study, we investigate the  $\beta$ -cell transdifferentiation function of IBCAP in the liver.

**Materials and methods:** STZ treated diabetic mice were randomized based on body weight, glucose, insulin and HbA1c. Liver samples and paraffin-embedded liver sections of STZ-treated diabetic mice infected with recombinant adenovirus intravenously over-expressing either IBCAP or a control protein GFP were analyzed. The microscopic examination of insulin expression in the liver was analyzed by immunostaining.

**Results:** 7 days after injection of IBCAP-expressing adenovirus into the tail vein of STZ-diabetic mice diabetic condition was improved and insulin expression in the liver was detected by immunostaining. Insulin positive cells were demonstrated in the liver of STZ treated type 1 diabetes model mice infected with IBCAP expressing adenovirus, but not in the mice infected with a control.

**Conclusion:** Our results demonstrated that expression of IBCAP can induce insulin-positive cells in the liver. We assume that IBCAP have an activity to induce the differentiation of the progenitor cells to insulin producing  $\beta$ -cells. We are currently working on this hypothesis.

## 431

**Defective proliferative and differentiation properties of human pancreatic islet derived mesenchymal cells from type 2 diabetic donors**

F.A. Grieco<sup>1,2</sup>, I. Spagnuolo<sup>1,2</sup>, A. Patti<sup>1,2</sup>, G. Sebastiani<sup>1,2</sup>, M. Bugliani<sup>3</sup>, L. Marselli<sup>3</sup>, P. Marchetti<sup>3</sup>, F. Dotta<sup>1,2</sup>;

<sup>1</sup>University of Siena, <sup>2</sup>Fondazione Umberto Di Mario ONLUS-Toscana Life Science, Siena, <sup>3</sup>University of Pisa, Italy.

**Background and aims:** It has been established that both in Type 1 and Type 2 diabetes (T2D) there is a significant loss of insulin-producing beta cells and consequently decreased functional beta cell mass. *In vitro* generation of insulin-producing cells from stem/progenitor cells is crucial to develop a proper cell-therapy for diabetes. Previously, we have obtained *in vitro* human pancreatic islet derived mesenchymal (hPIDM) cells able to de-differentiate from native islets, to proliferate and to re-acquire a pancreatic endocrine phenotype. Consequently, we aimed at investigating whether islets derived from T2D patients retain above mentioned properties observed in non diabetic donors.

**Materials and methods:** Human Pancreatic Islet-Derived Mesenchymal (hPIDM) cells were obtained by plating human pancreatic islets from T2D

donors in RPMI 1640 medium containing 10% FBS. For differentiation into a pancreatic endocrine phenotype, cells were cultured for 21 days in serum-free RPMI 1640 medium containing BSA, insulin, transferrin and sodium selenite (SFM). Proliferating and differentiated hPIDM cells were characterized by Real-Time-PCR and immunofluorescence analysis for expression of endocrine and mesenchymal markers. Glucose-induced C-peptide secretion was evaluated by RIA test.

**Results:** During de-differentiation, Real-Time-PCR after 15 days and after 6 passages of culture revealed a significant loss ( $p < 0.05$ ) of pancreatic endocrine genes (i.e. insulin, glucagon, somatostatin, Pdx-1) and an up regulation of mesenchymal genes (vimentin, nestin), compared to native islets. Double immunofluorescence analysis for insulin, nestin, vimentin, smooth muscle  $\alpha$ -actin and Ki-67, after 3, 6, 11 and 15 days of culture, showed disappearance of insulin positive cells at a faster rate in T2D patients vs control donors (3 days vs 10 days). Moreover, proliferative marker Ki67 appeared later in hPIDM cells obtained from T2D patients, and the growth curve showed reduced proliferative properties in such cells vs hPIDM cells from non-diabetic donors. After culture in SFM medium, cells re-acquired a pancreatic endocrine phenotype at gene expression level by real Time PCR; however, differently from what observed in control donors, cells obtained from T2D patients resulted negative for insulin, glucagon and somatostatin by immunofluorescence, nor released C-peptide after glucose stimulation.

**Conclusions:** Taken together these data show that islet cells from T2D patients are able to de-differentiate into hPIDM cells, which, however, show impaired proliferation and defective properties in terms of re-differentiation into a pancreatic endocrine phenotype, thus uncovering a “regenerative” defect in T2D. Such cells from may represent an *in vitro* model to test the capacity of new anti-diabetic drugs to induce/modulate beta cell regeneration. *Supported by: Tuscany Region*

## 432

### Co-culture of islets with mesenchymal stem cells in direct contact configurations improves islet function *in vitro*

P.K. Dhadda, C.L. Rackham, S.J.S. Simpson, P.M. Jones;  
Diabetes and Nutritional Sciences, School of Medicine, King's College London, UK.

**Background and aims:** Co-transplantation of islets with mesenchymal stem cells (MSCs) has been shown to enhance the outcome of islet transplantations *in vivo*, which may be a result of improved islet function. This study aimed to determine whether MSCs improve islet function when co-cultured with islets in different direct contact configurations *in vitro*.

**Materials and methods:** Kidney MSCs and pancreatic islets were isolated from C57BL/6 mice. Real time imaging sequences of fluorescently labelled MSCs or non-labelled MSCs, and non-labelled islets in suspension co-culture were captured to assess the interactions between MSCs and islets over a 72 hour time period. Islets were also cultured alone (IA), in suspension co-culture (SC) or cultured directly upon a monolayer of MSCs (MC) for 48 hours, and subsequently analysed for insulin content and glucose-stimulated insulin secretion by radioimmunoassay.

**Results:** *Real time imaging:* Real time imaging revealed that MSCs migrated rapidly towards and adhered to the surface of islets in a largely random manner, forming a mantle to increase islet size. Formation of the MSC-islet composite structures took place in a time dependent manner, with a maximal increase in islet diameter being measured after 36 hours ( $22 \pm 3\%$ ,  $n=3$ ,  $p < 0.05$  versus control). No further significant increase in islet diameter was seen after this time point. Real time fluorescence microscopy of islets co-cultured with fluorescent Qtracker-labelled MSCs revealed that MSCs formed an intact mantle around the perimeter of the islets and also penetrated and migrated into the islet structure. *Co-culture:* Islets cultured alone for 48 hours were able to secrete insulin in response to both intermediate (10mmol/l) and high (20mmol/l) concentrations of glucose (2mmol/l glucose:  $0.04 \pm 0.02$  ng/islet/h; 10mmol/l:  $0.08 \pm 0.03$ ; 20mmol/l:  $0.13 \pm 0.03$ ,  $n=9$ ,  $P < 0.05$ ). Glucose stimulated insulin secretion was enhanced when islets were co-cultured either as SC (2mmol/l:  $0.04 \pm 0.01$  ng/islet/h; 10mmol/l:  $0.15 \pm 0.08$ ; 20mmol/l:  $0.42 \pm 0.12$ ,  $n=9$ ) or as MC (2mmol/l:  $0.14 \pm 0.05$  ng/islet/h; 10mmol/l:  $0.89 \pm 0.22$ ; 20mmol/l:  $2.33 \pm 0.5$ ,  $p < 0.05$ ,  $n=9$ ) compared to islets alone. Both co-culture configurations resulted in elevated islet insulin content when compared to islets cultured alone (IA:  $9.7 \pm 3.0$  ng/islet; SC:  $13.9 \pm 0.7$ ; MC:  $23.8 \pm 7.5$ ,  $n=3$ ).

**Conclusion:** Both *in vitro* co-culture configurations were able to enhance islet function, which may have important implications for clinical islet transplantation practices. Pre-culturing islets on a monolayer of MSCs immediate-

ly after isolation, but prior to clinical transplantation, may serve as a superior option to culturing islets alone, while the formation of islet-MSC composites may provide an attractive option for the co-localised delivery of both cell types for intraportal delivery.

## 433

### Beta cell adaptation is topologically heterogeneous throughout the pancreas

J.H. Ellenbroek<sup>1</sup>, H.A. Töns<sup>1</sup>, N. de Graaf<sup>1</sup>, C.J.M. Loomans<sup>2</sup>, M.A. Engelse<sup>1</sup>, H. Vrolijk<sup>3</sup>, T.J. Rabelink<sup>1</sup>, F. Carlotti<sup>1</sup>, E.J.P. de Koning<sup>1,2</sup>;  
<sup>1</sup>Department of Nephrology, Leiden University Medical Center, <sup>2</sup>Hubrecht Institute, Utrecht, Netherlands, <sup>3</sup>Department of Molecular Cell Biology, Leiden University Medical Center, Netherlands.

**Background and aims:** Beta cells adapt to an increased insulin demand by enhancing insulin secretion via increased beta cell function and/or increased beta cell number. Insight into the mechanisms that control beta cell adaptation is important for developing therapies that can preserve or enhance beta cell mass. It is unknown whether there are regional differences in beta cell adaptation throughout the pancreas. We investigated beta cell adaptation in a model of high-fat diet (HFD)-induced insulin resistance in mice.

**Materials and methods:** C57BL/6 mice were fed a HFD or control diet for 6 weeks. Glucose and insulin tolerance tests were performed at the end of the study. BrdU was injected twice daily to label proliferating cells one week before sacrifice. The pancreas was divided in a duodenal (DR), gastric (GR) and splenic (SR) region and taken for either histology or islet isolation followed by a glucose-induced insulin secretion test. The capacity of islets from the three regions to adapt in an extrapancreatic location was assessed by transplantation of the untreated isolated islets under the kidney capsule of diabetic mice. BrdU was used to label proliferating cells (starting from day 3 post transplantation) and blood glucose levels were monitored for 10 days, after which the islet graft was taken for histology.

**Results:** As expected, HFD mice showed decreased insulin sensitivity compared to control mice. However, only SR islets showed increased  $\beta$ -cell proliferation (BrdU+/Ins+ cells  $5.8 \pm 1.2$  (HFD) vs.  $3.3 \pm 0.4\%$  (control),  $p < 0.05$ ). Furthermore, glucose-induced insulin secretion was increased twofold from isolated SR islets after HFD compared to DR and GR islets (insulin/DNA  $0.39 \pm 0.02$  (SR),  $0.23 \pm 0.03$  (DR),  $0.25 \pm 0.03$  (GR),  $p < 0.05$ ). Transplantation of islets from the SR, GR and DR in syngeneic diabetic mice led to a similar decrease in hyperglycaemia and there was no difference in beta cell proliferation (BrdU+/Ins+ cells  $24.5 \pm 2.2$  (DR),  $21.5 \pm 3.1$  (GR),  $25.0 \pm 1.7\%$  (SR),  $p = 0.53$ ) indicating that the regional peri-islet microenvironment of the pancreas is important for differential adaptive responses.

**Conclusion:** HFD-induced insulin resistance leads to topologically heterogeneous beta cell adaptation and is most prominent in the splenic region of the pancreas. This topological heterogeneity in beta cell adaptation is the result of extrinsic factors present in the islet microenvironment. Investigation of these regional differences may lead to the identification of novel factors involved in beta cell regeneration.

#### Evolution of diabetes complications 5 years after islet transplantation (IT) with the Edmonton immunosuppressive regimen

**D. Quintin<sup>1</sup>**, J. Warin<sup>1</sup>, A.-S. Balavoine<sup>1</sup>, F. Defrance<sup>1</sup>, J. Kerr-Conte<sup>2</sup>, C. Noel<sup>3</sup>, F. Pattou<sup>4</sup>, M.-C. Vantyghem<sup>1</sup>;

<sup>1</sup>Endocrinology and Metabolism, Lille University Hospital, <sup>2</sup>Inserm U 859, Lille University Hospital, <sup>3</sup>Nephrology, Lille University Hospital, <sup>4</sup>Endocrine Surgery, Lille University Hospital, France.

**Background and aims:** Long-term benefit-risk ratio of IT remains poorly evaluated. The aim of this work was to determine evolution of diabetes complications 5 years after IT.

**Materials and methods:** 21/36 consecutive patients transplanted in a single center, had at least 5 years of follow-up. Their initial features were: duration of C-peptide negative diabetes: 28±9 years; age: 44±7 years; BMI: 23±2 kg/m<sup>2</sup>; 8/21 kidney-transplanted patients for 25±10 months. These 21 patients had systematic screening for macro and micro-angiopathy before IT, and yearly for 5 years after IT. Two “islet-alone (ITA)” and 2 “islet-after-kidney (IAK)” patients had lost their islet function at 5 years. Ten patients (48%) were insulin-independent (II), 8/10 with HbA1c ≤ 6.5%. Mean HbA1c level was 8.1±1.0% before vs. 7.0±1.0% 5 years after IT (p<0.01). Analyses were performed in intention-to-treat. There was no loss of follow-up.

**Results:** Mean level of cholesterol total (1.88±0.42 vs. 1.75±0.34 g/l), HDL (0.71±0.18 vs. 0.73±0.27 g/l), LDL (0.98±0.32 vs. 0.88±0.30 g/l), triglycerides (TG) (0.87±0.45 vs. 0.81±0.34 g/l) and mean BP (124±14/74±8 vs. 129±13/72±8 mmHg) did not differ before vs. after transplantation (patients treated with statins: 28% vs. 65% and with ≥1 antihypertensive drug: 38% vs. 75%). There were no clinical acute cardiovascular events during these 5 years. Before vs 5 years post IT, anomalies were detected on carotid (37% vs. 52%) and lower limb ultrasound (22 vs. 25% after exclusion of vascular calcifications), myocardial scintigraphy (19% vs. 24%). Four patients required coronary stenting. Retinopathy mildly worsened in 5/37 (14%) eyes in 21 patients (5 blind eyes). It remained stable or improved in 32/37 eyes (86%). Post-prandial glucose levels (p<0.001), mean glucose (MG) and standard deviation (SD) on CGMS (p<0.01) were higher in the worsened group compared to the stable one. The evolution of visual acuity did not vary significantly over time in the whole group, but differed between ITA and IAK (p<0.05), perhaps in relation to a higher frequency of cataract in IAK patients (p=0.056). Patients with cataract had a higher level of TG, BP (p<0.01) and cholesterol (p<0.05). Serum creatinine level, glomerular filtration rate assessed with MDRD and microalbuminuria did not vary significantly between 0 and 5 years. Creatinine and MDRD correlated negatively with GAD antibodies (respectively p<0.001 and 0.05), positively with tacrolimus (p<0.01) and triglyceride (p=0.01); microalbuminuria correlated with βscore (p<0.05), TG (p<0.01), and systolic BP (p<0.001). The means of motor and sensitive potential amplitudes (p<0.05) and sensitive nerve conduction (SNC)(p<0.01) improved between 0 and 5 years in the whole group, mainly in correlation with βscore for the sensitive parameters, and C-peptide, MG and TG for the amplitudes.

**Conclusion:** IT was not associated with acute clinical cardiovascular event in these 21 IT patients at the expense of systematic screening and treatment of silent coronaropathy. Kidney function and visual acuity remained stable. Sensitive nerve conduction improved, suggesting that despite immunosuppressive regimen, the Edmonton protocol is able to stabilize or even improve diabetes complications.

#### Portal versus systemic venous drainage of pancreatic graft: the effect on glucose metabolism in pancreas and kidney transplant recipients

**T. Havrdova<sup>1</sup>**, F. Saudek<sup>1</sup>, P. Boucek<sup>1</sup>, T. Jedinakova<sup>1</sup>, K. Lipar<sup>2</sup>, M. Kocik<sup>2</sup>, J. Skibova<sup>3</sup>;

<sup>1</sup>Diabetes Center, Inst Clin Exp Medicine, Prague, <sup>2</sup>Transplant Center, Inst Clin Exp Medicine, Prague, <sup>3</sup>Statistical Department, Inst Clin Exp Medicine, Prague, Czech Republic.

**Background and aims:** Two different methods of graft venous drainage are used in pancreas transplantation: portal (PVD) and systemic (SVD). PVD

is considered as more physiologic due to similarity to venous outflow of the native pancreas. The aim of our study was to compare glucose metabolism in Type 1 diabetic recipients of kidney and pancreatic grafts with PVD versus SVD.

**Methods:** We examined 28 insulin-independent patients after simultaneous pancreas and kidney transplantation: 14 recipients with PVD of the pancreatic graft and 14 ones with SVD after a mean post transplant period of 1 year. All recipients had a stable good function of the kidney graft (mean serum creatinine level 103±19 [SD] μmol/l). Tacrolimus-based immunosuppression combined with mycophenolate mofetil or sirolimus was used in all patients. Fasting glycemia, insulin levels, HbA<sub>1c</sub>, a standard IVGTT with coefficient of glucose assimilation (K<sub>G</sub>) calculation and trough tacrolimus and sirolimus levels were assessed. Insulin sensitivity and production were evaluated using the homeostasis model assessment (HOMA-IR, HOMA-B). Total C-peptide and insulin secretions were calculated as areas under the curves from the serum levels during the IVGTT.

**Results:** PVD and SVD groups did not differ in age, BMI, duration of post transplant period, fasting C-peptide and insulin levels. We did not find any significant difference in response of IVGTT. In the PVD group 1 patient had an abnormal response to the glucose stimulus, 8 patients had an impaired glucose tolerance and 5 patients had a normal glucose tolerance. In the SVD group an abnormal response was present in none, the impaired glucose tolerance in 4 and the normal glucose tolerance in 10 recipients. Mean K<sub>G</sub> was 1.23±0.47 %/min. in the PVD group and 1.67±0.57 %/min. in the SVD group (p=0.12). The remaining results are shown in the following table. Trough levels of tacrolimus and sirolimus had no significant impact on any of the examined parameters.

**Conclusion:** Use of different types of venous drainage (of pancreatic graft) in Type 1 diabetic pancreas and kidney transplant recipients had no effect on glucose metabolism at one year post transplant.

	HbA1c DCCT (%)	Fasting glycemia (mmol/L)	HOMA-IR	HOMA-B	Total C-peptide secretion (pmol/ L/60min.)	Total insulin secretion (mIU/ L/60min.)
PVD group	5.41±0.32	4.89±0.55	1.17±0.82	19.0±16.9	93.3±31.0	1067±645
SVD group	5.69±0.27	4.7±0.72	2.64±2.26	51.6±46.4	96.3±31.0	1663±1136
Difference	p=0.09	p=0.57	p=0.1	p=0.07	p=0.86	p=0.22

### 436

#### Is PTP1B involved in the protective effect of tungstate on transplanted islets grafts?

**H. Figueiredo<sup>1,2</sup>**, A. Garcia<sup>1,2</sup>, H.S.M. Farghaly<sup>3</sup>, R. Fernandez<sup>1,2</sup>, A. Novials<sup>1,2</sup>, R. Gomis<sup>1,2</sup>, R. Malpique<sup>1,2</sup>;

<sup>1</sup>Diabetes and Obesity, IDIBAPS-Hospital Clinic, Barcelona, Spain,

<sup>2</sup>CIBERDEM, Barcelona, Spain, <sup>3</sup>Faculty of Medicine, Assiut, Egypt.

**Background and aims:** Islet transplantation is considered a potentially curative treatment for type 1 diabetes, however its clinical application remains conditioned by post-transplantation challenges, such as inflammation and poor revascularization of the engrafted islets. Previous recent results by our group showed that after transplantation of pancreatic islets into the anterior chamber of the eye of diabetic-induced mice, treatment with tungstate (a phosphatase inhibitor) improved glycemic levels, increased islet graft revascularization and reduced cell death. Based on these observations, as well as the knowledge of the roles of the tyrosine phosphatase PTP1B in angiogenesis, apoptosis and insulin secretion, we hypothesize that the beneficial action of tungstate on the survival and function of engrafted islets may be mediated by PTP1B inhibition.

**Materials and methods:** Islets isolated from wild-type and PTP1B-knockout mice were transplanted into the anterior chamber of the eye of diabetic-induced mice (streptozotocin -treated 8 days before transplantation). The animals were divided into 6 groups: T+W - transplanted (T) with wild-type islets, treated with sodium tungstate (W; 0.5 mg/ml water); T - transplanted, non-treated with W; KO+W - transplanted with PTP1B-KO islets, W-treated; KO - transplanted with PTP1B-KO islets, non-treated with W; CTRL+W: non-transplanted, W-treated; CTRL - non-transplanted, non-treated with W. In vivo studies were performed during 25 days of treatment to evaluate glycemic levels, islet revascularization and cell viability. Post-mortem morphometric

analysis and functional studies were conducted on graft-containing eyes and pancreas. To complement in vivo findings, in vitro studies were performed by culturing isolated islets for 24 hours in medium enriched with tungstate or serum from diabetic animals treated with tungstate. Immunohistochemistry analyses were conducted on intact islets using endothelial and islet-cell markers as well as markers of cell proliferation and apoptosis.

**Results:** Our results showed, for T+W, KO+W and KO groups, decreased glycaemic levels 25 days after transplantation ( $279 \pm 48$ ,  $271 \pm 91$  and  $287 \pm 78$  mg/dl, respectively), when compared to the values obtained for the T, CTRL+W and CTRL groups ( $449 \pm 34$ ,  $478 \pm 162$  and  $548 \pm 52$  mg/dl, respectively). Furthermore, when islet vascular density was analysed after in vivo dextran injection, the T+W, KO+W and KO groups showed an increased value regarding the T group ( $0.028 \pm 0.002$ ,  $0.030 \pm 0.003$  and  $0.026 \pm 0.004$  versus  $0.016 \pm 0.003$  %). In accordance with these findings, morphometric analyses of the graft-containing eyes revealed an increased percentage of endothelial cells on islets from the T+W, KO+W and KO groups when compared with the T group. In parallel, a significant 6% increase ( $p < 0.01$ ) in the endothelium cells (CD31 staining) content was found for islets incubated in medium with serum from diabetic animals treated with tungstate as compared to islets incubated in medium with serum from tungstate non-treated diabetic mice.

**Conclusion:** Our results support the hypothesis that the protective action of tungstate on engrafted islets may be mediated by a mechanism dependent on PTP1B inhibition. Future work will focus on further unravelling of the molecular mechanism involved in these findings.

### Layer-by-layer nanoencapsulation of human islets

F. Syed, S. Krol, M. Bugliani, M. Masini, M. Suleiman, L. Marselli, F. Filipponi, U. Boggi, P. Masiello, P. Marchetti;  
Endocrinology and Metabolism, Metabolic Unit, University of Pisa, Italy.

**Background and aims:** Promising results are being reported in islet transplantation to cure subjects with type 1 diabetes. A major problem remains the need for chronic immunosuppression, that however could be potentially overcome if the islets are coated with biocompatible, semipermeable membranes to protect from immunological attacks. Whereas the use of macro- or microencapsulation techniques has given conflicting results, an attractive strategy involves the use of conformal islet nanocoating, with reduced volumes and the possibility of implantation into any suitable site. In this study we coated isolated human islets (HI) by a multilayer nanoencapsulation procedure and assessed several beta cell features.

**Materials and methods:** HI were isolated from non-diabetic cadaveric donors (age:  $63 \pm 8$  yrs, BMI:  $31.4 \pm 6.4$  kg/m<sup>2</sup>, mean blood glucose at ICU stay:  $141 \pm 50$  mg/dl) by enzymatic digestion and density gradient purification. Chitosan [(Poly(D-glucosamine) Deacetylated chitin)] and PSS [(Poly(styrenesulfonic acid sodium salt)] were dissolved (1 mg/ml) in M199 culture medium and kept at 37°C for 36 hours. HI were then incubated in each polymer for 7 min and nanoencapsulation was achieved by electrostatic binding of chitosan and PSS layer-by-layer. Morphology, morphometry, ultrastructure, viability and insulin secretion studies were then performed with non-encapsulated and nanoencapsulated islets cultured for 7 days.

**Results:** The layer-by-layer encapsulation procedure provided full coating of all the islets, as assessed by confocal and fluorescence microscopy examination after the use of chitosan labeled with FITC. Vital staining with propidium iodide showed  $\geq 90\%$  cell survival at all the experimental conditions; this was confirmed by electron microscopy, that also showed well maintained beta cell ultrastructure of the coated islet cells, with unchanged morphometry of intracellular organelles. Insulin secretion from coated islets was  $60 \pm 37$  uU/ml at 3.3 mmol/l glucose and increased to  $197 \pm 56$  uU/ml at 16.7 mmol/l glucose ( $p < 0.01$ ), with a stimulation index of  $5.0 \pm 3.7$  (all values not significantly different from those obtained with uncoated islets).

**Conclusion:** Therefore, isolated human islets were efficiently encapsulated by layer-by-layer nanocoating, with maintained morphological, survival and functional properties, providing a tool for experimental transplantation studies.

### Free and encapsulated human pancreatic islets release insulin in response to hypotonicity in Ca<sup>2+</sup> independent manner

V. Štrbák<sup>1,2</sup>, Z. Bačovská<sup>1,2</sup>, G. Koláriková<sup>3</sup>, M. Orečná<sup>1</sup>, J. Oberholzer<sup>4</sup>, R. Hafko<sup>1</sup>, I. Lacík<sup>3</sup>;

<sup>1</sup>Inst. Exp. Endocrinology SAS, Bratislava, Slovakia, <sup>2</sup>Pathophysiology, Slovak Medical University, Bratislava, Slovakia, <sup>3</sup>Polymer Institute, SAS, Bratislava, Slovakia, <sup>4</sup>Department of Surgery, University of Illinois at Chicago, Chicago, USA.

**Background and aims:** We have previously shown that cell swelling induced by hypotonic medium reliably stimulates insulin secretion from rat pancreatic islets using unique signaling pathway including Ca<sup>2+</sup> independence and resistance to noradrenalin inhibition. The effect of cell swelling on insulin secretion from human islets has not been studied yet. This contribution shows this effect in post mortem isolated both free and encapsulated human pancreatic islets.

**Materials and methods:** Post mortem isolated islets were shipped from Chicago to Bratislava and encapsulated in sodium alginate-cellulose sulfate-poly(methyl-co-guanidine) microcapsules. Islets were incubated at basal and stimulated conditions either free or encapsulated within a semipermeable membrane, the latter as a part of our studies into immune protection of transplanted pancreatic islets by encapsulation. Free islets were also perfused with Ca<sup>2+</sup> containing or Ca<sup>2+</sup> depleted basal and stimulating media.

**Results:** Stimulation with 20 mM glucose or 30% hypotonicity induced insulin release from both free and encapsulated human islets (increase to 300 %,  $P < 0.001$  paired t-test between basal and stimulated group). Perfusion of free islets with Ca<sup>2+</sup> depleted medium revealed accentuated response to hypotonicity and depressed glucose-induced secretion.

**Conclusion:** Post mortem isolated human pancreatic islets, either free or encapsulated, release insulin in response to hypotonicity and glucose. Osmotically induced secretion is independent from extracellular Ca<sup>2+</sup>.

### Testing in vivo functionality of alginate-encapsulated pancreatic islets: advancing to the surgically-induced diabetic canine model

M. Ader<sup>1</sup>, R. Storrs<sup>2</sup>, J. Endres<sup>3</sup>, M. Lamb<sup>3</sup>, E.M. Paredes<sup>1</sup>, R.N. Bergman<sup>1</sup>, J.R.T. Lakey<sup>4</sup>;

<sup>1</sup>Cedars-Sinai Medical Center, Los Angeles, <sup>2</sup>Islet Sheet Medical LLC, San Francisco, <sup>3</sup>Dept. Surgery, University of California Irvine, Orange, <sup>4</sup>Depts. Surgery and Biomedical Engineering, University of California Irvine, Orange, USA.

**Background and aims:** Insulin (INS) replacement therapy using transplantation of pancreatic islets has held promise since reports of the Edmonton Protocol in diabetic patients. Efforts to improve islet viability and long-term functionality without chronic immunosuppression have spawned novel strategies including encapsulating islets in biocompatible polymers.

**Materials and methods:** Islet encapsulation into flat alginate sheets enables physiologic INS secretion from retrievable grafts. Islet viability and functionality was tested in vitro before or after s.c. transplantation into Lewis rats. Human islets from cadaveric donors from University of California Irvine were encapsulated into alginate hydrogel sheets after collagenase dissociation. Islet viability was quantified using Newport Green/propidium iodide. Islet function was determined from static glucose-stimulated INS release (GSIR), expressed as the Stimulation Index (SI; ratio of INS released at 28 mM and 2.8 mM glucose).

**Results:** Encapsulated human islets were  $95 \pm 0.2\%$  viable after encapsulation and 1 week in culture, and remained viable 8 weeks post-transplantation ( $73.0 \pm 1.5\%$ ). Glucose responsiveness (= SI) was  $3.8 \pm 0.2$  in tissue culture and  $3.0 \pm 0.5$ ,  $3.0 \pm 0.4$ ,  $1.5 \pm 0.5$ , and  $1.5 \pm 0.3$  at 1, 2, 4, and 8 weeks post-transplant, respectively. These results prompted further study to assess in vivo metabolic efficacy of alginate-encapsulated islets in a large animal model. INS-deficient diabetes will be induced in male dogs (BW = 25–30 kg) by surgical pancreatectomy (PANX). Glucose control will be maintained with rapid- and intermediate-acting INS (twice daily). Diabetes will be verified by absence of measurable endogenous INS and C-peptide response to i.v. glucose bolus (0.3 g/kg, IVGTT). To formulate islet sheets for canine transplantation, pancreata will be obtained from donor dogs after IVGTTs to verify robust  $\beta$ -cell function, using two donors per recipient to ensure adequate islet number for encapsulation. Two weeks post-PANX, diabetic dogs will be implanted with

four islet sheets into two ventral s.c. pockets. Functionality will be quantified from INS and C-peptide release during IVGTTs at day 5, 12, 26, and 54 post-transplantation, and repeated after graft explantation. *In vitro* islet viability and function will be tested by GSIR, and peri-sheet vascularization and lymphocyte infiltration will be assessed by histology of retrieved explant. **Conclusion:** Pancreatic islets encapsulated into alginate sheets demonstrate consistent viability and functionality in either tissue culture and within a small animal model, and are primed for comprehensive evaluation in a large animal model of INS-deficient diabetes. Canine studies described herein are critical for progression of this novel therapeutic modality towards clinical application.

### Preculture of islets with mesenchymal stem cells enhances islet function *in vitro* and produces superior transplantation outcome in diabetic mice

C.L. Rackham, P.K. Dhabda, A.A. Dattani, J.E. Bowe, P.M. Jones, A.J.F. King; Diabetes and Nutritional Sciences, King's College London, UK.

**Background and aims:** We have previously shown that co-transplanting mesenchymal stem cells (MSCs) enhances islet graft function and improves revascularisation *in vivo*. The aims of the present study were to determine whether preculturing islets with MSCs would improve islet function and maintain islet endothelial cell number *in vitro*. We also investigated whether preculturing islets with MSCs improves islet transplantation outcome in diabetic mice.

**Materials and methods:** Kidney MSCs and pancreatic islets were isolated from C57BL/6 mice. *In vitro*: Islets were cultured alone or with MSCs for three days using a direct contact co-culture system, after which islet insulin content and glucose-induced insulin secretion was measured. Islet beta cell number and endothelial cell number was analysed by histology. *In vivo*: Streptozotocin-diabetic C57BL/6 mice were implanted under the kidney capsule with a minimal mass of 150 islets which had been precultured alone or with MSCs. Blood glucose concentrations were monitored for 28 days. All cured mice were given an intraperitoneal glucose tolerance test at one month. Two days later the islet graft-bearing kidney was removed by nephrectomy to assess whether graft removal would result in reversion to hyperglycaemia.

**Results:** *In vitro*: Preculture of islets with MSCs potentiated glucose-stimulated (20mmol/l) insulin secretion ( $1.7 \pm 0.2$  vs  $2.8 \pm 0.3$  ng/islet/hr,  $p < 0.05$ ,  $n=5$ ). Islet insulin content was reduced in three day cultured islets, compared to those that were freshly isolated ( $39.8 \pm 3.6$  vs  $87.7 \pm 12.8$  ng/islet,  $p < 0.05$ ,  $n=5$ ). Preculturing islets with MSCs helped to prevent the decline in insulin content ( $77.4 \pm 6.3$  vs  $34.8 \pm 3.7$  ng/islet,  $p < 0.05$ ,  $n=5$ ). The number of insulin-positive beta cells per islet section was higher in MSC precultured islets compared to those cultured alone ( $83.7 \pm 5.1$  and  $54.4 \pm 6.5$  beta cells per islet section,  $n=4$ ,  $p < 0.05$ ). There was a rapid and dramatic loss of intraislet endothelial cells during culture ( $961.2 \pm 104.7$  vs  $72.9 \pm 9.0$  endothelial cells/mm<sup>2</sup>, freshly isolated vs. three day cultured islets,  $n=4$ ,  $p < 0.0001$ ). Preculturing islets with MSCs did not maintain intraislet endothelial cells ( $56.2 \pm 11.5$  vs  $48.8 \pm 12.4$  endothelial cells/mm<sup>2</sup>, MSC precultured islets and islets cultured alone,  $n=4$ ,  $p > 0.2$ ). *In vivo*: Islets which had been precultured with MSCs significantly lowered blood glucose at 7, 14, 21 and 28 days post-transplantation ( $p < 0.01$ ,  $n=10$ ). Day 28: Islet + MSC =  $8.2 \pm 0.4$  mmol/l vs islet alone =  $19.5 \pm 3.1$  mmol/l. At one month, all mice in the MSC precultured islets transplant group had cured compared to only 40% of mice transplanted with islets cultured alone. The glucose tolerance of cured mice was similar between transplant groups. All cured mice reverted to hyperglycaemia ( $>20$  mmol/l) on removal of the graft-bearing kidney. The density of endothelial cells was similar in the endocrine tissue of islet grafts consisting of islets cultured alone and islets precultured with MSCs ( $676 \pm 32.3$  vs  $631.8 \pm 80.2$  endothelial cells/mm<sup>2</sup>,  $n=4$ ,  $p > 0.05$ ).

**Conclusion:** Preculture of islets with MSCs does not affect endothelial cell number *in vitro* or *in vivo*, but does improve islet function and transplantation outcome. This may have implications for improving islet culture for clinical transplantation.

## 441

### The development of a method to preserve endothelium cells during human islet isolation

G.C. Huang<sup>1</sup>, M. Zhao<sup>1</sup>, P. Srinivasan<sup>2</sup>, P. Chondhary<sup>1</sup>, H. Tang<sup>1</sup>, N. Heaton<sup>2</sup>, S. Amiel<sup>1</sup>;

<sup>1</sup>Diabetes and Endocrinology, King's College London, <sup>2</sup>Liver Transplantation, King's College Hospital, London, UK.

**Background and aims:** Successful human islet transplantation depends not only on the mass of human islets and their viability but on how quickly the islets can get revascularisation. The current human islet isolation procedures deprive the endothelium tubelets from the islets. We aim to preserve more islets endothelium cells during the islet isolation to promote islet revascularisation following transplantation.

**Materials and methods:** Human pancreas organs with research consent were used in this study. Our modified method is to deliver collagenases and neutral protease (Serva) to pancreas in a sequential manner in comparison with those that the two types of enzyme were delivered at the same time (standard method). The enzymes and reagents used for the islet isolation is the same between the two methods. The silicon nitride marbles were removed from the Recordi's digestion chamber to avoid potential physical damages to islets. The pancreatic digestive was incubated with UWS supplemented with 2% of human albumin during tissue collecting phase. The ability of the islets to revascularise was assessed by transplanting the human islets under the kidney capsule in chemical induced diabetes mice. The graft-bearing kidneys were analysed by immunohistochemical staining.

**Results:** There were no obvious differences in the donor characteristics used in the study between the two methods. The means islet IEQ using modified method ( $n=21$ ) is  $390121 \pm 130015$  and their viability is  $85 \pm 6\%$ . The means islet IEQ using standard method ( $n=10$ ) is  $357321 \pm 113561$  and their viability is  $83 \pm 7\%$ . The islet yield and viability of the modified method are not significant difference from the standard method ( $P=0.08$  for the islet yield and  $p=0.15$  for the viability respectively). The islets from the modifying method, however, have  $20 \pm 10\%$  islets with attached endothelium cell tubelets in comparison with no endothelium cells attached to islets in the standard method. More interestingly these islets with endothelium cells attached seemed to have achieved rapid revascularisation within 3 days post transplant in diabetic mice, while the islets from standard methods showed little revascularisation on day 3 post transplantation.

**Conclusion:** Our modified method is a more gentle approach to generate human islets. This leads to the retaining of some endothelium cells with the islets. The retaining endothelium seemed to contribute the revascularisation processing and to improve the engraftment of islets. Islets from this modified method have higher capacity to revascularise and might have important implication in human islet transplantation.

### Resolving complexity of the IC2 autoantibody recognised target on the surface of functional beta cells by cellular and molecular affinity measurements

I.D. Pedersen<sup>1</sup>, K.L. Jensen<sup>1</sup>, C. Käck<sup>2</sup>, T. Aastrup<sup>2</sup>, M. Cárdenas<sup>3</sup>, M. Blaise<sup>4</sup>, K. Buschard<sup>1</sup>, C.-H. Brogren<sup>1</sup>;

<sup>1</sup>The Bartholin Institute, Rigshospitalet, Copenhagen, Denmark, <sup>2</sup>Attana AB, Stockholm, Sweden, <sup>3</sup>Nano-Science Center, University of Copenhagen, Denmark, <sup>4</sup>Department of Molecular Biology, Aarhus University, Denmark.

**Background and aims:** The rat monoclonal autoantibody IC2, raised in a newly diabetic BB-rat, has been shown to have a unique specificity for the surface of insulin secreting pancreatic  $\beta$ -cells. The target autoantigen for IC2 has been partially characterized by high-performance thin-layer chromatography combined with radioimmunoassay and lipid microarrays and it appears to be specific for sulphated glycolipids and sphingomyelins isolated from RIN-5F or INS-1E rat  $\beta$ -cells as well as their purified plasma membranes. Previous affinity measurements towards  $\beta$ -cells, sulfatides and sphingomyelins indicate a complex nature of the IC2 autoantigen. The reactivity seems to be directed primarily towards galactose-3-sulphate on sulfatides and phosphocholine residues on sphingomyelins though also phosphatidylcholines exhibits binding. Trypsin treatment abolishes IC2 binding to  $\beta$ -cells, which indicates that a protein structure might either be a part of the  $\beta$ -cell surface autoantigen, or function as carrier for the autoantigen. Recently, IC2 was found to have an inhibitory effect on NKT type I and II cells which points

towards formation of the targeted epitope in a complex between the pancreatic islet  $\beta$ -cell expressed CD1d and noncovalently anchored phospho- and glycolipids, since these are known to stimulate NKT cells.

**Materials and methods:** Both cellular and molecular real-time quartz crystal microbalance (QCM) experiments and molecular microscale thermophoresis (MST) experiments were performed. Affinities were measured towards intact INS-1E cells, sonicated plasma membrane vesicles, lipid rafts, lipids, and lipids anchored to the CD1d protein, as well as several different complexes and combinations of these.

**Results:** Cellular QCM showed that IC2 has a very strong affinity towards intact INS-1E cells with a dissociation constant of 1.39 nM and an association rate of  $1.54 \times 10^5 \text{ M}^{-1} \text{ s}^{-1}$  (Figure). Several different molecular components were examined by molecular QCM. MST measurements showed a medium-strong affinity of IC2 towards lysosulfatide with a dissociation constant of 1  $\mu\text{M}$ . Affinities were compared and ranked in order to elucidate and resolve the complexity of the autoantigen.

**Conclusion:** Getting closer to a characterization of the autoantigen leads to potential new therapeutic approaches by using IC2 in drug delivery. These results are also of massive importance to the development of IC2 as a functional biomarker for the  $\beta$ -cell mass. This could lead to a characterization of the diabetic process and an improved focus of therapeutic interventions in both T1DM and T2DM patients, by being able to closely follow the effects of treatment with growth promoting drugs (e.g. GLP-1 agonists), stem-cell therapy, and islet transplantation.

### Evaluation of immunogenicity of insulin-producing gut cells in diabetes-prone mice

M. Mojibian<sup>1</sup>, A.W.Y. Lam<sup>1</sup>, Y. Fujita<sup>2</sup>, A. Asadi<sup>1</sup>, G.A. Grassl<sup>3</sup>, P. Dickie<sup>4</sup>, A.T. Cheung<sup>5</sup>, T.J. Kieffer<sup>1</sup>;

<sup>1</sup>Cellular & Physiological Sciences, University of British Columbia, Vancouver, Canada, <sup>2</sup>Department of Internal Medicine, Asahikawa Medical University, Asahikawa, Hokkaido, Japan, <sup>3</sup>Michael Smith Laboratories, Vancouver, Canada, <sup>4</sup>University of Alberta, Edmonton, Canada, <sup>5</sup>enGene, Inc., Vancouver, Canada.

**Background and aims:** Type 1 diabetes is caused by autoimmune destruction of pancreatic  $\beta$ -cells, but the mechanisms involved are not well-understood. Intestinal K-cells are glucose-responsive, native endocrine cells that may be good candidates for engineering into surrogate  $\beta$ -cells to restore endogenous insulin secretion. We have generated diabetes-prone NOD (non-obese diabetic) transgenic mice with targeted expression of insulin to gut K-cells (GIP/Ins mice). These transgenic mice are protected from developing both chemically-induced and spontaneous diabetes. The aim of this study was to determine the immunogenicity and impact of insulin producing gut K-cells in NOD mice.

**Material and methods:** The incidence of spontaneous diabetes was determined in transgenic and non-transgenic NOD mice. Histology and insulin immunoreactivity were evaluated in pancreas and duodenum of these animals. We evaluated T cell immune responses to insulin using a CFSE proliferation assay and the frequency of circulating T cells with a tetramer assay. Serial plasma samples were collected from 6-24 weeks to profile insulin autoantibodies.

**Results:** The incidence of hyperglycemia was markedly reduced in 2 cohorts of GIP/Ins NOD mice that produced insulin in K-cells (non-transgenic vs transgenic: 100% (n=22) vs 45% (n=19) at 32 wks, and 90% (n=11) vs 15% (n=14) at 44 wks).  $\beta$ -cell inflammation and damage were reduced in pancreas of transgenic mice compared to controls, and insulin<sup>+</sup> K-cells remained intact with no sign of inflammation. We evaluated pancreas sections from 32 wk transgenic mice, an age by which all non-transgenic mice had succumbed to diabetes (n=22), and found that 7 of 10 transgenic mice had little or no insulinitis. In a different cohort of 32 wk old mice, we examined the proliferation of cells isolated from mesenteric lymph nodes (MLN) in the presence of insulin; the cell division index in MLN cells from transgenic mice was significantly lower compared to non-transgenic mice ( $p < 0.03$ ). At 15 wks (before diabetes) transgenic animals had a lower frequency of peripheral CD8<sup>+</sup> T cells specific to NRP-V7 compared with controls ( $p < 0.03$ ). We also detected a reduced number of insulin autoantibody-positive transgenic animals compared to controls (cumulative incidence of 46 vs 80% in non-transgenic vs transgenic mice, respectively by 24 wks). Moreover, while there was a clear predictive value in the number of insulin autoantibody-positive control mice that subsequently developed diabetes (88%), this was not the case in the GIP/Ins transgenic mice (16%).

**Conclusion:** Insulin is generally thought to be a key autoantigen responsible for the selective elimination of  $\beta$ -cells. However, our data indicate that gut-derived insulin not only prevents hyperglycemia, but also provides protection against diabetes in the setting of autoimmune assault against  $\beta$ -cells. Collectively, our results suggest that gut-derived insulin reduces the immune response to insulin, which may explain the protection of gut insulin-producing cells, and also the delay in immune attack of pancreatic  $\beta$ -cells. Targeting gut K-cells may be useful for insulin replacement therapy, as well as inducing tolerance and diminishing autoimmunity.

**Pancreatic overexpression of IGF-I protects NOD mice from autoimmune diabetes**C. Mallol<sup>1,2</sup>, A. Casellas<sup>1,2</sup>, V. Jimenez<sup>1,2</sup>, E. Casaña<sup>1,2</sup>, M. Morro<sup>1,2</sup>, M. Obach<sup>1,2</sup>, J. Agudo<sup>1,2</sup>, E. Ayuso<sup>1,2</sup>, F. Bosch<sup>1,2</sup>;<sup>1</sup>Department of Biochemistry and Molecular Biology and Centre of Animal Biotechnology and Gene Therapy, Universitat Autònoma de Barcelona, Bellaterra, <sup>2</sup>CIBERDEM, Barcelona, Spain.

**Background and aims:** Both type 1 and 2 diabetes result from reduced  $\beta$ -cell mass. Recent studies have implicated insulin and insulin-like growth factor I (IGF-I) signaling pathways in the regulation of  $\beta$ -cell proliferation. We have previously shown that expression of IGF-I under control of the rat insulin-I promoter (RIP-I) in  $\beta$ -cells of transgenic mice counteracts cytotoxicity and insulinitis, and regenerates the endocrine pancreas after treatment with streptozotocin. In addition,  $\beta$ -cell expression of IGF-I protects islets from autoimmune destruction in IFN- $\beta$  transgenic mice, a model of lymphocytic infiltration of endocrine pancreas. To further investigate the role of IGF-I preventing from autoimmune diabetes, here we analyze the effect of IGF-I expression in  $\beta$ -cells of type 1 diabetes-prone Nonobese Diabetic (NOD) mice.

**Materials and methods:** Transgenic mice overexpressing murine IGF-I under the control of the RIP-I Promoter were backcrossed with NOD mice for 15 generations to obtain IGF-I transgenic mice with 99% NOD genetic background. Blood glucose levels and other metabolic parameters, body weight, and leukocyte infiltration were analyzed.

**Results:** Pancreatic expression of IGF-I in  $\beta$ -cells of NOD transgenic mice prevented the development of diabetes. While 63% of wild type NOD mice developed diabetes at 30 weeks of age, only 10% of NOD IGF-I transgenic mice became diabetic, and 80% of individuals remained normoglycemic at the age of 10 months. Thus, the incidence of autoimmune diabetes in female NOD IGF-I transgenic mice was significantly reduced. Immunostaining against insulin revealed a preservation of  $\beta$ -cell mass and a reduction of leukocytic infiltration of islets. Serum insulin levels in NOD transgenic mice were also higher than in control mice. To further confirm the protective effect of IGF-I, transgenic RIP/IFN $\beta$  mice were injected via retrograde pancreatic intraductal administration with adeno-associated viral vectors (AAV) expressing IGF-I under control of the RIP promoter. Preliminary results indicate that AAV-mediated expression of IGF-I into the pancreas of adult RIP/IFN $\beta$  mice is also able to prevent the diabetic process. Studies investigating the molecular mechanisms by which IGF-I exerts this protection are being conducted in our laboratory.

**Conclusion:** This study indicates that local expression of IGF-I in the pancreas prevents islet infiltration and  $\beta$ -cell death in mice with increased susceptibility to type 1 diabetes development. Thus, IGF-I may represent a key factor to prevent autoimmune destruction of  $\beta$ -cells in type 1 diabetes.

## 445

**Toll-like receptor 4 deficiency mediates insulin resistance in prediabetic NOD mice and accelerates the progression of autoimmune-mediated diabetes**A.L. Reinbeck<sup>1</sup>, G. Séquaris<sup>1</sup>, H.J. Partke<sup>1</sup>, P. Nowotny<sup>1</sup>, J. Kotzka<sup>2</sup>, B. Knebel<sup>2</sup>, V. Burkart<sup>1</sup>, M. Roden<sup>1,3</sup>;<sup>1</sup>Institute for Clinical Diabetology, German Diabetes Center, Duesseldorf,<sup>2</sup>Institute for Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, <sup>3</sup>Department of Metabolic Diseases, University Clinics Duesseldorf, Germany.

**Background and aims:** The pathogenesis of type 1 diabetes is characterized by immune-mediated destruction of autologous pancreatic beta cells. Recent observations indicate that disturbances of energy metabolism contribute to disease progression. Previous studies demonstrated an important role of toll-like receptor 4, a receptor for lipopolysaccharide on innate immune cells, in the control of (auto-)immune processes as well as energy metabolism. We therefore hypothesized that TLR4 determines a diabetes-modulating metabolic phenotype in non-obese diabetic (NOD) mice.

**Materials and methods:** Age and blood glucose levels at diabetes manifestation were monitored in female TLR4-expressing (TLR4<sup>+/+</sup>) and TLR4-deficient (TLR4<sup>-/-</sup>) NOD mice. Glucose tolerance was assessed in 6-hours fasted mice by intraperitoneal glucose tolerance tests (ipGTT). Mitochondrial func-

tion was determined by high-resolution respirometry. Insulin and IL-6 serum concentrations were quantified by sandwich ELISA.

**Results:** TLR4<sup>-/-</sup> NOD mice developed diabetes earlier in life ( $152 \pm 25$  days) than TLR4<sup>+/+</sup> NOD mice ( $208 \pm 40$  days,  $p < 0.001$ ). Furthermore, TLR4<sup>-/-</sup> NOD mice had increased blood glucose concentrations at the onset of diabetes when compared to TLR4<sup>+/+</sup> mice (TLR4<sup>-/-</sup>  $457 \pm 30$ , TLR4<sup>+/+</sup>  $362 \pm 44$  mg/dl,  $p < 0.001$ ). Moreover, in the prediabetic period, normoglycemic TLR4<sup>-/-</sup> mice had markedly lower glucose tolerance (area under the glucose curve: TLR4<sup>-/-</sup>  $587 \pm 152$  mmol/L x h<sup>-1</sup>, TLR4<sup>+/+</sup>  $233 \pm 102$  mmol/L x h<sup>-1</sup>,  $p < 0.001$ ). Upon ipGTT, insulin concentrations were doubled in TLR4<sup>-/-</sup> compared with TLR4<sup>+/+</sup> mice. Fasting serum free fatty acid levels were 40% higher in TLR4<sup>-/-</sup> than in TLR4<sup>+/+</sup> mice. In TLR4<sup>-/-</sup> NOD mice, hepatic but not myocellular mitochondria showed increased O<sub>2</sub>-flux through complex I and II (TLR4<sup>-/-</sup>  $54.6 \pm 14.8$ , TLR4<sup>+/+</sup>  $29.6 \pm 7.4$  (pmol x mg<sup>-1</sup> x s<sup>-1</sup>)/mtDNA copy number,  $p < 0.05$ ) and higher maximal respiratory capacity (TLR4<sup>-/-</sup>  $87.8 \pm 18.6$ , TLR4<sup>+/+</sup>  $55.5 \pm 22.7$  (pmol x mg<sup>-1</sup> x s<sup>-1</sup>)/mtDNA copy number,  $p < 0.01$ ) when compared to TLR4<sup>+/+</sup> NOD mice. Furthermore, TLR4-deficient NOD mice had higher serum concentrations of the proinflammatory cytokine interleukin-6 (TLR4<sup>-/-</sup>  $4.8 \pm 0.9$  pg/ml, TLR4<sup>+/+</sup>  $2.3 \pm 0.5$  pg/ml;  $p < 0.001$ ).

**Conclusion:** Taken together, TLR4 deficiency decreases insulin sensitivity resulting in increased substrate availability and subsequently enhanced O<sub>2</sub>-flux in liver mitochondria. This indicates that TLR4 controls the progression of immune-mediated diabetes in NOD mice by impairing insulin sensitivity.

## 446

**The pathology underlying beta cell destruction in four type 1 diabetes animal models in comparison with the human situation**A. Jörns<sup>1</sup>, C. Mathieu<sup>2</sup>, C. Gysemans<sup>2</sup>, F. Scott<sup>3</sup>, G.-S. Wang<sup>3</sup>, Y. Nakaya<sup>4</sup>, N. Harada<sup>4</sup>, P. Marchetti<sup>5</sup>, L. Marselli<sup>5</sup>, S. Lenzen<sup>1</sup>;<sup>1</sup>Institute of Clinical Biochemistry, Hannover Medical School, Germany,<sup>2</sup>Laboratory for Experimental Medicine and Endocrinology, Catholic University of Leuven, Belgium, <sup>3</sup>Chronic Disease Program, Ottawa Hospital Research Institute, Canada, <sup>4</sup>Institute of Health Biosciences, University of Tokushima Graduate School, Japan, <sup>5</sup>Section of Endocrinology and Metabolism of Organ Transplantation, University of Pisa, Italy.

**Background and aims:** The aim of the study was to compare the immune cell infiltrate and the cytokine pattern in pancreatic islets leading to beta cell loss in the four spontaneous type 1 diabetes animal models, namely the NOD mouse, the BB rat, the LEW.1AR1-*iddm* rat, and the Komedra rat with the human situation after type 1 diabetes development.

**Materials and methods:** After diabetes manifestation pancreases from NOD mice, BB, LEW.1AR1-*iddm*, and Komedra rats were analysed by immunohistochemistry and by *in situ* RT-PCR for the immune cell composition of the infiltrate and the cytokine pattern including proliferation and apoptosis rate in comparison with the human situation and normoglycaemic controls.

**Results:** In the pancreatic islets from normoglycaemic controls of the rodents as well as of humans beta cells were the main cell type; there were no signs of immune cell infiltration both in the islets and in the exocrine pancreatic parenchyma including the vessels. Without infiltration no cytokine expression was observed in any pancreatic parenchymal cell type. After type 1 diabetes manifestation an immune cell infiltration was found in the islets. With declining frequency CD8 T cells, CD68 macrophages, and CD4 T cells were observed as the main immune cell types, independent from the analysed animal model as well as in pancreases from patients. In the human situation B cells and in the NOD mice regulatory T cells expressing FoxP3 were more frequently found. IL-1 $\beta$  and TNF- $\alpha$  were expressed as the main pro-inflammatory cytokines in the immune cell infiltrate in the NOD mice, BB and LEW.1AR1-*iddm* rats, and in the human situation while in the Komedra rat, as an exception, IFN- $\gamma$  and TNF- $\alpha$  were the main cytokines as a sign of immune cell activation. Additionally, the autoimmune process supporting IL-17 cytokine was expressed in infiltrated islets. Also, the anti-inflammatory cytokines, IL-4, IL-10, and IL-13 were found in some immune cells in each islet infiltrate. Ultrastructurally confirmed apoptotic beta cell death (apoptosis rate between 0.9 - 3.2 % by the TUNEL assay) was observed in the pancreatic islets from the animal models and also in the human situation. Under all diabetic conditions proliferating beta cells (proliferation rate between 0.5 - 2.1 % by the Ki67 and insulin immunostaining), were also found in islets with remaining beta cells.

**Conclusion:** The main immune cells, cytotoxic CD8 T cells, CD4 T cells, and CD68 macrophages, were similar in all animal models to the human situation. Pro-inflammatory patterns were TNF- $\alpha$ , IL-1 $\beta$ , and IFN- $\gamma$  with decreasing frequency expressed in the infiltrating immune cells as a sign of activation

leading to beta cell apoptosis. The exception was the Komeda rat, where a dominance of IFN- $\gamma$  instead of IL-1 $\beta$  expression was observed in parallel to TNF- $\alpha$  expression. Thus animal models of type 1 diabetes can serve as good models providing meaningful information also for the understanding of the disease processes in the pancreas of patients with type 1 diabetes.

## 447

### Treg-mediated suppression of autoimmune diabetes in mice following non-viral-mediated hepatic overexpression of IGF-I

F. Bosch<sup>1</sup>, S. Tafuro<sup>2,3</sup>, C. Roca<sup>2,3</sup>, D. Callejas<sup>2,3</sup>, J. Agudo<sup>2,3</sup>, M. Obach<sup>2,3</sup>, A. Ruzo<sup>2,3</sup>, C.J. Mann<sup>2,3</sup>, A. Casellas<sup>2,3</sup>, X.M. Anguela<sup>2,3</sup>;  
<sup>1</sup>CIBERDEM, Universitat Autònoma de Barcelona, Bellaterra, <sup>2</sup>Department of Biochemistry and Molecular Biology, School of Veterinary Medicine, Universitat Autònoma de Barcelona, Bellaterra, <sup>3</sup>CIBERDEM, Barcelona, Spain.

**Background and aims:** In type 1 diabetes, loss of tolerance to  $\beta$ -cell antigens results in T cell-dependent autoimmune destruction of  $\beta$ -cells. The abrogation of autoreactive T cell responses is a prerequisite to achieve long-lasting correction of the disease. Hepatic gene transfer may result in tolerance induction and suppression of autoimmune diseases, in part by regulatory T cell (Treg) activation. The unique immunomodulatory properties of the liver could hence be manipulated to treat or prevent diabetes onset through expression of key genes. Thus, in the context of an autoimmune disease like type 1 diabetes, a liver-targeted gene therapy approach to modify peripheral control of autoreactive lymphocytes offers a unique possibility to prevent development and progression of the disease. Insulin-like growth factor-I (IGF-I) may be an immunomodulatory candidate since it prevents autoimmune diabetes when expressed in  $\beta$ -cells or subcutaneously injected. We have previously reported that local expression of IGF-I also protects islets from autoimmune destruction in an IFN- $\beta$  transgenic mouse model of type 1 diabetes. All these studies reveal IGF-I as a potential key factor to induce protection from autoimmune diabetes. Here, we aimed to determine whether transient IGF-I overexpression in mouse liver may suppress autoimmune diabetes progression.

**Materials and methods:** Heterozygous male transgenic mice expressing human IFN $\beta$  under the control of the rat insulin promoter-I (RIP-I) treated with streptozotocin (25 mg/kg bw) were used as a model of type 1 diabetes. Hepatic expression of IGF-I and eGFP was achieved following hydrodynamic tail vein injection via the lateral vein of plasmid DNA in saline in a volume equal to ~10% of body weight in less than 5 seconds. eGFP and IGF-I were expressed from plasmids containing either the CAG, hAAT or CD68 promoters. **Results:** In this work, we report a decrease in the incidence of diabetes following hepatic delivery of a plasmid expressing IGF-I by hydrodynamic tail vein (HTV) injection, in an autoimmune mouse model of the disease. We show that the expression of IGF-I in liver non-parenchymal cells leads to reduced  $\beta$ -cell apoptosis, increased  $\beta$ -cell replication and decreased pancreatic infiltration by immune effector cells, suggesting a blockage of the autoimmune attack against the pancreas. As a consequence, normalized  $\beta$ -cell mass, circulating insulin levels and glucose tolerance in STZ-treated mice were achieved. Permanent protection depended on IGF-I expression in liver non-parenchymal cells and was associated with increased percentage of intrahepatic and intrapancreatic Tregs. Importantly, Treg depletion completely abolished IGF-I-mediated protection confirming the therapeutic potential of these cells in autoimmune diabetes.

**Conclusion:** This study demonstrates that a non-viral gene therapy combining the immunological properties of the liver and IGF-I could be beneficial in the treatment of the disease.

### Overexpression of vitamin-D receptor in beta cells alters beta cell functionality but protects mice from diabetes

A. Casellas<sup>1,2</sup>, C. Mallol<sup>1,2</sup>, V. Jimenez<sup>1,2</sup>, M. Obach<sup>1,2</sup>, M. Morro<sup>1,2</sup>, J. Agudo<sup>1,2</sup>, E. Ayuso<sup>1,2</sup>, M. Molas<sup>1,2</sup>, R. Lage<sup>1,2</sup>, F. Bosch<sup>1,2</sup>;  
<sup>1</sup>Department of Biochemistry and Molecular Biology and Center of Biotechnology and Gene Therapy, Universitat Autònoma de Barcelona, Bellaterra, <sup>2</sup>CIBERDEM, Barcelona, Spain.

**Background and aims:** Vitamin D3 is obtained through the diet or by synthesis in skin, but only the 1,25(OH)<sub>2</sub>D3 form of vitamin D is metabolically active. This molecule exerts its effects by activating the nuclear vitamin D

receptor (VDR), which is a member of the nuclear receptor superfamily. Epidemiological studies have revealed an association between VDR gene polymorphism and diabetes. It has also been shown that vitamin D deficiency predisposes individuals to diabetes, and inhibits pancreatic insulin secretion in rodents and rabbits. Here, we aimed to determine the role of VDR in  $\beta$ -cell physiology and its effects in diabetes protection.

**Materials and methods:** Transgenic mice overexpressing murine VDR specifically in  $\beta$ -cells under control of the Rat Insulin Promoter-I (RIP-I) were obtained. Blood glucose levels, body weight and other metabolic parameters were analyzed and glucose tolerance test were performed. To induce diabetes, two-month-old mice were treated with low doses of streptozotocin (STZ, 5x50 mg/ Kg bw).

**Results:** Three lines (L1-L3) of RIP/VDR transgenic mice were obtained. All lines expressed VDR in islets. After double immunostaining against insulin and VDR we observed that the VDR expression was restricted to  $\beta$ -cells. The VDR-L1 line, which presented the highest level of expression of the transgene, showed slight hyperglycemia compared to wild type littermates in fed and fasted conditions, although insulin levels were not significantly different between the two groups. Moreover, VDR-L1 transgenic mice showed an increase in  $\beta$ -cell mass, and impaired glucose tolerance. VDR-L3, which showed low expression of the transgene, also exhibited impaired glucose tolerance, but no alteration in fed and fasting glycemia. To examine the role of VDR in  $\beta$ -cell protection against damage, wild type and VDR-L1 transgenic mice were treated with STZ. In contrast to STZ-treated wild type mice, which were hyperglycemic, STZ-treated VDR-L1 transgenic mice showed a reduction in glycemia and improved glucose tolerance test. These results correlated with serum insulin levels, which were higher in STZ-treated transgenic mice than in STZ-treated wild type mice.  $\beta$ -cell mass was also higher in STZ-treated VDR-L1 transgenic mice. Further studies aimed at understand the effects of VDR overexpression in  $\beta$  cells are presently carried out in our laboratory.

**Conclusion:** These results indicate that local overexpression of VDR in  $\beta$ -cells affects  $\beta$  cell functionality. Moreover, VDR overexpression may protect mice from diabetes.

### Prediction and prevention of islet infiltration using RIB5/2 antibody in the LEW.1AR1-iddm rat model of autoimmune diabetes

T. Schoeppe<sup>1</sup>, H. Weiss<sup>1</sup>, G. Fuellen<sup>2</sup>, M. Tiedge<sup>1</sup>;  
<sup>1</sup>IBIO, University of Rostock, <sup>2</sup>IBIMA, University of Rostock, Germany.

**Background and aims:** The LEW.1AR1-iddm rat is an animal model of spontaneous autoimmune diabetes. Islet infiltration occurs within a narrow time range resulting in progressive beta cell destruction and overt diabetes. It was the aim of this study to investigate (1) the predictive potential of gene expression profiling in peripheral mononuclear cells of the blood (PBMC) and (2) tolerance-inducing effects through treatment by the modulating anti-CD4 antibody RIB5/2 on islet infiltration in the prediabetic period.

**Materials and methods:** 6 LEW.1AR1-iddm rats were treated at the age of 40, 42, 44, 46 and 48 days with the monoclonal antibody RIB5/2 (5 x 5 mg Ab/kg b.w. i.p.). 200  $\mu$ l blood were collected at day 40 before antibody application and day 60. Normoglycaemic LEW.1AR1-iddm rats were killed at day 40 (n = 16). Serial pancreatic sections were stained with Haematoxylin-Eosin (HE) to document the status of infiltration. RNA was isolated from gradient-purified PBMCs. Gene expression was quantified for proinflammatory (TNF $\alpha$ , IFN $\gamma$ , IL-1 $\beta$ ) and antiinflammatory cytokines (IL-4, IL-10), T-cell markers (CD25, CTLA4, NRP1), L-Selectin, TGF- $\beta$  and FoxP3 by RT-PCR. The RT-PCR results were analysed by decision tree classification in the weka data mining tool using C4.5 algorithm for day 40.

**Results:** The decision tree classification showed, that from our panel of analysed genes, IL-1 $\beta$  expression (IL-1 $\beta$ /GAPDH ratio >144.66) was predictive in PBMCs for pancreatic infiltrations at day 40. Treatment with the anti-CD4 antibody RIB5/2 resulted in a significantly (P<0.05) reduced gene expression levels of IL-1 $\beta$ , TNF $\alpha$ , IL-10, NRP1 and TGF- $\beta$  (1.4 - 2.3-fold) 12 days after the last administration of RIB5/2 (d60). The reduction of IL-1 $\beta$  expression due to RIB treatment was able to prevent 100 % of the animals from infiltrations. At day 60 RIB5/2 treated animals showed a significant (P<0.05) reduction for PBMC gene expression of L-Selectin (4.5-fold), CD25 (2.6-fold), TGF- $\beta$  (2-fold), FoxP3 (2.7-fold) and CTLA4 (16-fold) compared with non-infiltrated rats. Gene expression levels of IL-4 was significantly higher (3.6-fold, P<0.05) in non-infiltrated animals. Those animals showing pancreatic infiltrations revealed significant (P<0.05) higher gene expression profiles of the cytokines TNF $\alpha$  (4.5-fold), IFN $\gamma$  (3.6-fold)

compared to RIB ab treated animals at day 60. Also the T-cell marker gene NRP1 (8-fold) was upregulated at this late point of autoimmunity. We also found that a significant ( $P<0.05$ ) reduction of the regulatory marker FoxP3 (2.3-fold) and the T-cell ligand L-Selectin (4.9-fold) in infiltrated animals was linked to a 7.5-fold reduced CTLA4 expression (T-cell silencing). **Conclusion:** Decision tree analyses of PBMCs allow to predict different stages of islet infiltrations of normoglycaemic LEW.1AR1-*iddm* rats. The anti-CD4 antibody RIB5/2 could induce tolerance against beta cell autoimmunity that induced gene signatures in PBMCs. IL-1 $\beta$  expression in combination with L-Selectin and TNF $\alpha$  proved to be a predictive marker for the early phase of islet infiltration. RIB resulted in a downregulation of proinflammatory cytokines genes and increased levels of regulatory T-cell marker genes. Our data indicate that analysis of gene expression profiles in PBMCs from risk patients could be an attractive strategy to monitor islet autoimmunity. Furthermore our data favor modulatory anti-CD4 abs as an attractive option for prevention of overt T1DM.

### Role of vitamin D in regulation of phagocytic function and CD4/CD8 splenic lymphocyte ratios in mice with STZ-induced diabetes

D. Labudzynski, I. Shymanskyi, V. Riasnyi, M. Veliky;

Laboratory of medicine biochemistry, Palladin Institute of Biochemistry, Kyiv, Ukraine.

**Background and aims:** Growing evidence suggests that alterations arising from abnormal immune responses are the major causes of type 1 diabetes and its complications. Beyond its classical calcium-regulating role in bone metabolism, vitamin D3 (D3) is currently recognized as a potent immunomodulator affecting the activities of macrophages, monocytes and lymphocytes in various autoimmune diseases. However, the precise mechanisms of D3 influence on immune homeostasis, immunity and tolerance in diabetes has not been clearly defined. We therefore investigated the relationship between D3 status and such immune parameters as functional competence of peripheral blood phagocytes and CD4/CD8 splenic T-lymphocyte ratios in diabetes and after chronic administration of D3.

**Materials and methods:** Type 1 diabetes was induced in male C57BL/6 mice (weighing  $25.0 \pm 1.5$ g) by i.p. injection of multiple low dose streptozotocin (40 mg/kg b.w.). Control and STZ-diabetic mice were maintained with or without treatment with D3, at 15 IU/mouse per os, for 8 weeks (a prevention paradigm). Serum 25-hydroxyvitamin D3 (25OHD3) was assessed by ELISA. The neutrophil and monocyte phagocytosis after exposure to FITC-labeled *E. coli* was determined quantitatively using flow cytometry and qualitatively by confocal laser scanning microscopy. Intracellular reactive oxygen species (ROS) were detected by 2',7'-dichlorofluorescein (DCF) fluorescence. Spleen lymphocytes were phenotyped using direct immunofluorescence staining after incubation with monoclonal antibodies specific for CD4 and CD8 cell markers by flow cytometry.

**Results:** Serum level of 25OHD3, the main circulating metabolite of D3, was shown to be reduced to  $23.8 \pm 1.9$  in diabetes vs.  $39.7 \pm 2.9$  in control, indicative of diabetes-induced D3 deficiency ( $p<0.05$ ). These changes were accompanied by decreased percentage of polymorphonuclear neutrophils and monocytes which ingest FITC-labeled *E. coli* and their activity (number of bacteria per cell) in diabetic mice. As further evidence of diabetes-associated dysfunction of peripheral blood phagocytes that may lead to impaired host defense against bacterial or fungal infections, decreased leukocytes ability to oxidize the fluorogenic substrate DCF was also found. In addition, lower immunoregulatory index indicating alteration of CD4/CD8 (helper/suppressor) lymphocyte ratio in spleen was observed in diabetic group as compared to control ( $1.43 \pm 0.12$  vs.  $1.80 \pm 0.15$  respectively,  $p<0.05$ ). Complete normalization of circulatory 25OHD3 levels was achieved due to D3 treatment. D3 administered to diabetic mice effectively restored production of ROS and phagocytic activity of cells towards the control values. Furthermore, it notably attenuated the immune imbalance observed in diabetes by up-regulating CD4/CD8 splenic lymphocyte ratio. D3 therapy had no effect on normal mice, except that the compound could augment the 25OHD3 levels. D3 treatment provided beneficial effects beyond glucose control because hyperglycaemia remained only slightly affected.

**Conclusion:** The study confirmed that diabetes was associated with impairment of phagocytic activity and redistribution in splenic lymphocyte subsets that correlated with vitamin D3 deficits. D3 possesses immunotherapeutic effects on mice with type 1 diabetes through improving the cell-mediated immunity.

### Disease recurrence after syngeneic islet transplantation in diabetic NOD mice is driven exclusively by pre-activated autoreactive T-cells

G.M. Alkemade<sup>1,2</sup>, X. Clemente-Casares<sup>1</sup>, J. Zhenguo Yu<sup>1</sup>, J. Wang<sup>1</sup>, B.-Y. Xu<sup>3,4</sup>, J.R. Wright, Jr.<sup>3</sup>, B.O. Roep<sup>2</sup>, P. Santamaria<sup>1,5</sup>;

<sup>1</sup>Julia McFarlane Diabetes Research Center, University of Calgary, Canada,

<sup>2</sup>Department of Immunohematology and Blood Transfusion, Leiden

University Medical Center, Netherlands, <sup>3</sup>Department of Pathology,

University of Calgary, Canada, <sup>4</sup>Alberta Diabetes Institute, University of

Alberta, Edmonton, Canada, <sup>5</sup>Institut d'Investigacions Biomèdiques August

Pi i Sunyer, Barcelona, Spain.

**Background and aims:** We have recently shown that T-cell recruitment to a site of autoimmune inflammation results from an active process that is strictly dependent on local display of cognate pMHC. We tested whether this revised paradigm also applies to recruitment of islet-specific T-cells into islets transplanted under the kidney capsule of diabetic NOD mice. Specifically, we addressed the contribution of memory IGRP<sup>206-214</sup> + CD8<sup>+</sup> T-cell in graft failure.

**Materials and methods:** Recruitment of IGRP<sup>206-214</sup> + CD8<sup>+</sup> cells into islet grafts from NOD.*scid* (expressing IGRP<sup>206-214</sup>) or NOD.*rag2*<sup>-/-</sup>.IGRP<sup>K209A/F213A</sup> donors (lacking IGRP<sup>206-214</sup>) was tracked in diabetic NOD hosts (harboring both naïve and memory IGRP<sup>206-214</sup> + CD8<sup>+</sup> cells) or diabetic NOD.IGRP<sup>K209A/F213A</sup> hosts (harboring naïve IGRP<sup>206-214</sup> + CD8<sup>+</sup> cells only) (n=5/ group). The presence of graft associated IGRP<sup>206-214</sup> + CD8<sup>+</sup> cells was quantitated through NRP-V7 tetramer staining and FACS analysis and IFN $\gamma$  secretion upon exposure to NRP-V7-pulsed dendritic cells was measured.

**Results:** Diabetes recurred significantly later in NOD hosts receiving IGRP-negative islet grafts than in those receiving wildtype islets (mean graft survival  $13.6 \pm 5.0$  vs  $5.5 \pm 0.7$  days;  $p<0.01$ ). IGRP<sup>206-214</sup> + T-cells were undetectable in IGRP-negative islet grafts, but accounted for a major fraction of T cells infiltrating IGRP<sup>+</sup> islet grafts ( $p=0.004$ ). In IGRP naïve hosts, IGRP<sup>206-214</sup> + T-cells remained undetectable in both IGRP+ islet grafts and islet grafts lacking this epitope.

**Conclusion:** Recognition of islet antigen is a prerequisite for T-cell recruitment in endogenous islets as well as in islet autografts. IGRP<sup>206-214</sup> + CD8<sup>+</sup> T-cells contribute to, but are dispensable for, rejection of islet grafts in diabetic NOD mice. Islets, transplanted under the kidney capsule, neither activate nor recruit naïve IGRP<sup>206-214</sup> -reactive CD8<sup>+</sup> T-cells early in the recurrent autoimmune response. Instead, recurrent diabetes is driven exclusively by memory autoreactive T-cells that had been primed during the development of spontaneous autoimmune diabetes. Our findings underscore the need for clinical treatment strategies managing chronic auto-immunity.

## PS 022 Intervention in type 1 diabetes

452

### Metabolic parameters at baseline identify clinical responders to teplizumab 2 years after diagnosis of type 1 diabetes

K.C. Herold<sup>1</sup>, M. Ehlers<sup>2</sup>, K. Boyle<sup>3</sup>, J. McNamara<sup>4</sup>, S. Gitelman<sup>5</sup>, P. Gottlieb<sup>6</sup>, C. Greenbaum<sup>7</sup>, W. Hagopian<sup>8</sup>, J.A. Bluestone<sup>9</sup>;

<sup>1</sup>Immunobiology, Yale University, New Haven, <sup>2</sup>Immune Tolerance Network, San Francisco, <sup>3</sup>Rho Inc, Chapel Hill, <sup>4</sup>NIAID, Bethesda, <sup>5</sup>Pediatrics, UCSF, San Francisco, <sup>6</sup>Medicine, University of Colorado, Aurora, <sup>7</sup>Benaroya Research Institute, Seattle, <sup>8</sup>Pacific Northwest Research Institute, Seattle, <sup>9</sup>Medicine, UCSF, San Francisco, USA.

**Background and aims:** Some patients with T1D, treated with humanized FcR non-binding anti-CD3 mAb, teplizumab, have had improved C-peptide responses to a mixed meal for as long as 2 years after diagnosis but not all trials have achieved their endpoint and parameters that can identify individuals before treatment most likely to respond to therapy have not been identified.

**Materials and methods:** We conducted an open-labelled trial of teplizumab in 83 patients with new onset T1D. Patients were randomised to treatment with two 14-day courses of teplizumab, 1 year apart, or intensive diabetes care, in a 2:1 ratio. The endpoint was a comparison of the change from baseline of the mean stimulated C-peptide 4-hour AUC responses to a mixed meal after 2 years. We identified clinical responders (post-hoc) as individuals whose C-peptide AUC at 24 months had fallen by  $\leq 40\%$  of the response at study entry.

**Results:** The intention to treat analysis included 52 drug-treated and 25 control subjects; of the drug-treated subjects, 40 received all/part of the 2<sup>nd</sup> drug cycle. Teplizumab treatment significantly reduced the decline in baseline C-peptide at month 24 (primary endpoint:  $-0.283$  ( $0.3155$ ) vs.  $-0.458$  ( $0.1555$ ) pmol/mL,  $p=0.002$ ) and reduced insulin use over 2 years ( $p=0.036$ ) to achieve HbA<sub>1c</sub> levels that were not significantly different ( $p=0.697$ ). A greater percentage of control subjects (33%) lost detectable stimulated C-peptide compared to teplizumab treated subjects (4%,  $p=0.001$ ). Although the C-peptide AUC responses represented a continuum, 22/52 of the drug-treated but none of the control subjects lost  $\leq 40\%$  of responses at 24 months. In the responding subjects, the C-peptide responses at 12, 18, and 24 months were 114%, 108%, and 88% of baseline whereas in the non-responders the responses were 57%, 39%, and 29% of baseline responses ( $p<0.001$  at all). The clinical responders were indistinguishable from the non-responders in age, weight, BMI, sex, duration of disease, autoantibodies, and baseline C-peptide responses. However, they had a lower baseline HbA<sub>1c</sub> ( $7.05$  ( $0.815$ ) vs  $7.71$  ( $1.030$ ) %,  $p<0.016$ ) and insulin dose ( $0.24$  ( $0.138$ ) vs  $0.46$  ( $0.246$ ) U/kg,  $p<0.005$ ).

**Conclusion:** Teplizumab treatment of patients with new-onset T1D significantly improves C-peptide response for at least 2 years after disease onset. A group of clinical responders who show little decline in C-peptide over this time have lower HbA<sub>1c</sub> and insulin use at diagnosis. These findings suggest metabolic memory that may affect responses to immune therapies.

### Effects of the GLP-1 receptor agonist liraglutide on human peripheral immune cells from healthy subjects in vitro and in vivo

G. Bock<sup>1</sup>, B. Prietl<sup>1</sup>, M. Tauschmann<sup>1</sup>, E. Höller<sup>1</sup>, C. Neuper<sup>1</sup>, W. Graninger<sup>2</sup>, T.R. Pieber<sup>1,3</sup>;

<sup>1</sup>Endocrinology and Metabolism, University Hospital Graz, <sup>2</sup>Rheumatology and Immunology, University Hospital Graz, <sup>3</sup>HEALTH - Institute of Biomedicine and Health Science, Joanneum Research, Graz, Austria.

**Background and aims:** Glucagon-like peptide-1 receptor agonists (GLP-1RA) are used as a novel therapy in type 2 diabetes. Treatment with GLP-1RA in T2D patients with psoriasis suggested immunomodulatory effects of GLP-1RA and anti-inflammatory effects in preclinical studies had been observed. In this study, we investigated the in vitro effect of liraglutide on human immune cells as well as the in vivo effect on the frequency of immune competent cells in the peripheral blood of healthy subjects.

**Materials and methods:** Proliferation of PBMCs from healthy donors was tested in vitro after exposing cells to increasing concentrations of liraglutide (0–80 µg/ml). Unstimulated cells and cells stimulated by adding anti-CD3/CD28 dynabeads were exposed to liraglutide and tested for their proliferation after 96 h. In vivo tests were done in a pilot trial including 5 healthy subjects (2f/3m; age:  $35\pm9$  years; BMI:  $25.1\pm4.9$ ) who were initially treated with 0.6 mg liraglutide/day followed by 1.2 mg/day for a total of 4 weeks. A multi-color FACS analysis for Treg, B-, iNKT-, NKT-, NK-, Th1-, Th2-, Th17 cells and DCs was performed at baseline (BL), after 2 and 4 weeks.

**Results:** In vitro PBMC proliferation of unstimulated cells increased 2–3 fold upon addition of liraglutide (20, 40, 80 µg/ml) whereas proliferation of stimulated cells did not change. In vivo peripheral Treg in CD4<sup>pos</sup>Tc increased significantly from  $4.64\pm1.06$  (BL) to  $5.74\pm1.14$  after 2 wks ( $p=0.001$ ) and  $5.52\pm0.83$  after 4 wks ( $p=0.004$ ) whereas Helios expression remained stable. The frequency of Th1-cells decreased significantly ( $7.50\pm2.42$  at baseline to  $4\pm1.96$  after 4 weeks,  $p=0.002$ ) whereas all other cell types remained stable.

**Conclusion:** Our study is first to show immunomodulatory effects of liraglutide treatment in healthy human subjects and our results advance the mechanistic insight into the immunomodulatory potential of incretin hormones in vitro and in vivo. Our findings provide further rationale to investigate potential beneficial effects of GLP-1RA treatment in autoimmune diseases such as T1D.

### Effect of anti-thymocyte globulin (ATG) on preserving beta cell function in new-onset type 1 diabetes

S.E. Gitelman<sup>1</sup>, L.K. Fisher<sup>2</sup>, P.A. Gottlieb<sup>3</sup>, M. Gottschalk<sup>4</sup>, W.V. Moore<sup>5</sup>, A. Moran<sup>6</sup>, M.R. Rigby<sup>7</sup>, S.M. Willi<sup>8</sup>, L. Keyes-Elstein<sup>9</sup>, A. Pinckney<sup>9</sup>, L. Ding<sup>10</sup>, M.R. Ehlers<sup>11</sup>, START Study Team;

<sup>1</sup>Pediatric Diabetes Program, University of California San Francisco, <sup>2</sup>Endocrinology, Children's Hospital of Los Angeles, <sup>3</sup>Pediatrics, Barbara Davis Center, Aurora, <sup>4</sup>Pediatric Endocrinology, University of California San Diego, <sup>5</sup>Endocrine/Diabetes, Children's Mercy Hospital, Kansas City, <sup>6</sup>Pediatric Endocrinology, University of Minnesota, Minneapolis, <sup>7</sup>Pediatrics, Indiana University, Indianapolis, <sup>8</sup>Pediatrics, Children's Hospital of Philadelphia, <sup>9</sup>Biostatistics, RhoFed, Inc., Chapel Hill, <sup>10</sup>DAIT, National Institute of Allergy and Infectious Diseases, Bethesda, <sup>11</sup>Clinical Trials Group, Immune Tolerance Network, San Francisco, USA.

**Background and aims:** Type 1 diabetes (T1D) results from T-cell mediated destruction of insulin-producing beta cells. Prior preclinical and clinical studies show that therapies targeting T-cells preserve beta cell function. Most promising are results with anti-thymocyte globulin (ATG): several doses can induce a lasting remission in the NOD mouse, and several smaller pilot clinical studies with ATG alone or in combination with other drugs preserve endogenous insulin secretion. We now report the results of a two-arm, randomized, placebo-controlled, blinded, phase 2 clinical trial in recent-onset T1D.

**Materials and methods:** Subjects aged 12–35 were screened and enrolled within 100 days of T1D diagnosis. They were randomized 2:1 to ATG or placebo, and underwent identical procedures throughout the trial. Drug/placebo was administered over a 5-day observation period in a clinical research center; those in the treatment group received a total ATG dose of 6.5 mg/kg. Subjects were followed closely over the ensuing 2 years. Primary endpoint is endogenous insulin secretion, as assessed by 2-hour C-peptide AUC in

response to a mixed-meal tolerance test at month 12. Secondary measures include safety experience, additional metabolic measures, and immunologic studies to assess mechanism of action. The sample size is calculated to have 80% power to detect 50% improvement in the treatment arm (2-sided t-test, alpha 5%, assuming 10% drop-out rate).

**Results:** 58 subjects were randomized to the trial, with median age of 17.5 years, 35 males, and 49 with primary race of white. All except 2 subjects completed the full study drug infusion course. 29 serious adverse events were reported for 13 subjects; 7 events were attributed to study drug. Cytokine release syndrome or serum sickness was noted in 38 subjects, and was managed with glucocorticoids for < 2 weeks duration. 38 subjects also exhibited decreased lymphocyte or CD4 counts; 68% had CD4 counts recover to > 200 x 10<sup>6</sup>/L by month 6, and 91% by month 12. No unusual or unexpected infections were noted, nor was cytomegalovirus or Epstein Barr virus reactivation observed. The primary endpoint data and additional secondary measures will be available in June, 2012, and will be reported at the time of the meeting.

**Conclusion:** ATG is a potential means to arrest beta cell destruction and induce tolerance for subjects with T1D. Mechanistic studies are underway to determine how this drug functions in vivo, with prior studies suggesting depletion of autoreactive T cells coupled with induction of regulatory T cells. Long term follow-up is ongoing to assess the durability of response.

### Evaluation of treatment effect of a type 1 diabetes intervention therapy using GST versus MMTT

S. Dagan<sup>1</sup>, D. Peled<sup>1</sup>, D. Elias<sup>1</sup>, A. Avron<sup>1</sup>, R. Eren<sup>1</sup>, I. Raz<sup>2</sup>, P. Pozzilli<sup>3</sup>; <sup>1</sup>Andromeda Biotech Ltd., Yavne, Israel, <sup>2</sup>Diabetes Unit, Department of Medicine, Hadassah University Hospital, Jerusalem, Israel, <sup>3</sup>Universita Campus Bio-Medico, Rome, Italy.

**Background and aims:** Endogenous insulin secretion by pancreatic beta cells is measured by stimulated C-peptide area under the curve (AUC). C-peptide stimulation is achieved by either intravenous administration of glucagon (GST) or ingestion of a mixed meal (MMTT), two standard assays that are commonly used. These procedures were compared previously in terms of sensitivity, reproducibility, and tolerability. However, a comparison between the two methods in measuring the treatment effect of type 1 diabetes (T1D) interventions, evaluated by the change in C-peptide AUC during the treatment period, was not performed. Our goal is to compare the changes in C-peptide AUC from baseline to end of treatment as measured by GST and MMTT.

**Materials and methods:** A phase III clinical study, DIA-AID 1, was conducted to evaluate safety and efficacy of DiaPep277 in preserving beta cell function in newly diagnosed T1D patients. We compared the C-peptide values of 151 patients in the placebo arm who had the AUC measured at least at baseline and after 24 months and evaluated the change from baseline to 24 months of C-peptide AUC using GST and MMTT.

**Results:** We correlated C-peptide AUC and the change from baseline AUC ( $\Delta$ AUC), measured by GST and MMTT in each individual patient at different time points. When comparing the AUC, the correlation coefficients range between 0.73–0.86 with time, improving at 24 months as compared to baseline. However, when comparing the  $\Delta$ AUC, we found no correlation between the two assays in all time points (correlation coefficients range between 0.35–0.57). Correlation between the change in fasting C-peptide ( $\Delta$  Fasting C-peptide) and change in AUC ( $\Delta$  AUC) from baseline to 24 months, measured by each of the two assays was better when using the GST. The clinical outcomes from the DIA-AID 1 study, HbA1c, insulin dose and number of hypoglycemic events at study end, support the finding that DiaPep277 led to a significant treatment effect in C-peptide  $\Delta$ AUC ( $p=0.035$ ) as measured by GST.

**Conclusion:** Although both GST and MMTT are reproducible and correlate well in evaluating absolute levels of C-peptide, there is a significant difference between the two tests in terms of measuring the change in C-peptide levels overtime. Further studies should be conducted to explore the nature of these discrepancies.

## 456

### Functional modulation of epidermal dendritic cells by topical steroid treatment to optimise the tolerogenic potential of immunotherapy for type 1 diabetes

M. Alhadj Ali, S. Hanna, S. Wong, C. Dayan;

Centre for Endocrine and Diabetes Sciences, Cardiff University, UK.

**Background and Introduction:** Administration of short peptides corresponding to T cell target sequences (peptide immunotherapy) has been shown to be a simple and effective method of restoring tolerance and reversing disease in animal models of T1D and has several potential advantages over other approaches to Antigen Specific Immunotherapy. In humans use of the intradermal route has a specific advantage in peptide immunotherapy as dendritic cells are potentially accessible for both peptide immunotherapy and local treatment with agents able to maintain the tolerance state.

**Aims and objectives:** We aimed to determine whether topical pretreatment of the skin with Betamethasone has the potential to enhance the tolerogenic response in peptide immunotherapy.

**Materials and methods:** 8 healthy volunteers received 0.05% Betamethasone twice daily for 4 days to the skin of a small area of the left arm. At day 5, all volunteers had a 10–15mm suction blister raised at the site of treatment and a second (control) blister raised in the right arm. Epidermal cells from treated and untreated skin were used separately to stimulate Mixed Epidermal Cells Lymphocyte Reaction (MECLR) using allogeneic PBMCs from healthy donor (B) and used also in a 14 days culture in combination with CD4+ CD45RA+ naive T cells from (B). T cells recovered from these cultures were added to a fresh MLR response to test their suppressive capacity. Natural T Regs (CD4+ CD25+ CD127 low) were separated from donor (B) and used as a positive control to suppress the MLR. PBMCs taken from the blister donor were used also in combination with PBMCs from (B) to stimulate a Mixed Lymphocyte Reaction (MLR).

**Results:** MECLR responses driven by epidermal cells from the steroid treated arm were 60.9% lower than with cells from the untreated arm ( $P=0.001$ ). MECLR responses were “normalized” to the MLR response and MECLR/MLR was also markedly reduced in the steroid treated arm compared with the ratio calculated from the control arm (60.3% difference -  $P=0.008$ ). After 14 days culture, T cells recovered from culture with epidermal dendritic cells (EDC) from the steroid treated arm markedly tended to suppress a fresh MLR response more than T cells induced by culture containing (EDC) from the control arm (Mean reduction=61.86% with SD=36.35%). MLR responses with NTregs separated from (B) were 89% lower than with T cells recovered from culture with untreated epidermal dendritic cells (SD= 5.88%).

**Conclusion:** Pretreatment of the skin with Betamethasone for as little as 4 days has significant effects on epidermal dendritic cells function shown in the Mixed Epidermal Cells Lymphocyte Reaction. The pilot functional studies indicate the ability of steroid treated epidermal dendritic cells to induce T cells which are able to suppress the proliferation of autologous naive T cells. Further functional assays are required to determine whether these represent T Reg cells and the mechanism of suppression induced by steroid topical therapy.

**Metabolic and immunologic observations from a trial of alpha -1 antitrypsin in recent onset type 1 diabetes**

P. Gottlieb, A. Michels, D. Di Domenico, L. Fitzgerald-Miller, K. Johnson, J. Lungaro, L. Meyers, A. Conley, D. Zipris;  
Pediatrics/Medicine, Barbara Davis Center, Aurora, USA.

**Background and aims:** Immune therapy of type 1 diabetes (T1D) to date has focused on therapies to affect T lymphocytes. These therapies have been able to interrupt the disease process, but in time it resumes and destruction of beta cells and loss of C-peptide ensues. Inflammation may be playing a role in setting the milieu which propagates and allows the autoimmune process to be maintained. Alpha-1 antitrypsin (AAT) has been shown to be effective in the NOD mouse and islet transplantation models where it has an ability to downregulate many pro-inflammatory pathways. This study was designed as a pilot to understand the metabolic and immunologic effect of AAT in recent onset T1D.

**Materials and methods:** This study was a single center, open label, safety and efficacy study where individuals who were autoantibody positive, within 5 years of diagnosis who retained measurable C-peptide were given 8 weekly infusions of AAT at 80/mg/kg. Endpoints included safety, AAT levels, metabolic endpoints as well as inflammatory and T cell markers. A mixed meal test was performed at baseline, 3, 6, 9 and 12 months and the 2 hour C-peptide AUC was assessed.

**Results:** 12 subjects were enrolled in the trial and all subjects completed their infusions. There were mild AE's observed which included headache and hypoglycemia. No SAE's were observed. We divided subjects into those with >1 year duration vs. those with < 1 year duration. We saw some drop in C-peptide among the 4 subjects with >1 year duration, while insulin use and HbA1c was essentially unchanged during the 3 months of therapy. In contrast for those with <1 year duration, we saw 4 out of 7 subjects had an increase in C-peptide at 3 months, while 3 of 7 decreased their insulin use as well. HbA1c remained well controlled throughout the treatment period. Trough AAT levels were progressively raised throughout the 8 weeks of treatment, but did not exceed the normal range at the doses used in this study. Immunologic assays to look at modulation of TLR-induced inflammatory signals in monocyte and dendritic cells failed to demonstrate a consistent effect of AAT.

**Conclusion:** AAT was well tolerated and safe in the doses used in the study. There was suggestion of metabolic effect of the study drug in those with more recent onset, but it is not clear how that effect is being mediated from this pilot trial. Further trials with more subjects, additional doses and additional biomarkers are warranted to better understand the role and effect of anti-inflammatory therapy in T1D.

**Therapeutic effects produced by administration of human preproinsulin gene in rodents with experimental type 1 diabetes mellitus**

M.D. Tronko<sup>1</sup>, O.I. Kovzun<sup>1</sup>, L.N. Kalynska<sup>1</sup>, I.P. Paster<sup>1</sup>, V.A. Kordum<sup>2</sup>, T.P. Gulko<sup>2</sup>, O.K. Toropova<sup>2</sup>;

<sup>1</sup>State Institution "V.P.Komisarenko Institute of Endocrinology and Metabolism of Natl. Acad. Med. Sci. Ukraine", <sup>2</sup>Institute of Molecular Biology and Genetics of Natl. Acad. Sci. Ukraine; State Institution, Kyiv, Ukraine.

**Background and aims:** Insulin-dependent diabetes mellitus is associated with an almost complete destruction of insulin-producing pancreatic beta-cells, which leads to insulin deficiency in the body. A radical treatment of diabetes may be provided by gene therapy - namely, by administration to patients of a human insulin gene in molecular construction that would provide its expression in non-specific cells which do not produce endogenous insulin.

**Materials and methods:** The molecular vector construction consisted of two independent modules: a bacterial plasmid backbone allowing its replication in *Escherichia coli* cells, and an expression cassette with a target full-size gene of preproinsulin, flanked by inverted terminal repeats of human adeno-associated virus 2. Human cytomegalovirus immediate-early promoter was used to drive ectopic insulin transgene expression in liver cells. A branched polyethyleneimine (25 kD) has been used to transfect liver cells *in vivo*. We have used a model of diabetes in Wistar rats and C57BL/6j mice to study the effects of recombinant molecules that contain a target gene of human preproinsulin. Streptozotocin (STZ) (Sigma, U.S.A.) was administrated to male animals aged 2 to 2.5 months every day for 5 days at a dose 50 mg/kg. The signs of STZ diabetes development in animals were a loss of weight, an increased blood

glucose level and polyuria. One month after STZ administration, animals with developed hyperglycemia (17.5 to 29.2 mmol/L) were divided into three groups: diabetic animals which were injected with vector DNA containing human preproinsulin gene, and two control groups: diabetic animals which did not receive DNA and diabetic animals which received control plasmid DNA without target gene. DNA/polyethyleneimine complexes for injections were prepared in a weight equivalent 1:3. DNA amount in transfection preparation was 10 µg per 20 g of weight. The therapeutic effect of injected recombinant molecules was assessed according to glucose content in blood plasma of experimental animals - by glycemia level four hours after the last meal. Glucose was tested using a test-system "Hemoglan" from ("Norma", Ukraine) and on an analyzer "SUPER GL" (Germany).

**Results:** The data obtained revealed a significant decrease in blood glucose level in 85% of experimental animals after preproinsulin gene administration. The tendency to glucose levels decrease has also been revealed in experiments with plasmid control. Within 5 to 12 weeks after STZ administration the majority of animals from control groups have demonstrated high glycemia levels, loss of weight, polyuria, and a high lethality rate which exceeded by several times the rate for experimental animals. The decrease in blood glucose level (22.4 to 13.3 mmol/L) with term 2.5-5 weeks was shown in diabetic rats (5 weeks diabetes) 1 week after molecular vector DNA administration.

**Conclusion:** These results show that regression of diabetes has been achieved after a single course of gene therapy on the model of experimental type 1 diabetes in rats and mice. This approach could be used to study islet physiology and to assay new gene therapy approaches for diabetes mellitus.

**11-Keto-β-boswellic acid prevents development of insulinitis in NOD-mice**

H.P.T. Ammon<sup>1</sup>, A.M. Shehata<sup>2</sup>, J. Jauch<sup>3</sup>, L. Quintanilla-Martinez<sup>4</sup>;  
<sup>1</sup>Pharmacology and Toxicology, Pharmaceutical Institute, University of Tübingen, Germany, <sup>2</sup>Pharmacology and Toxicology, Faculty of Pharmacy, University of Beni-Suef, Egypt, <sup>3</sup>Organic Chemistry, Institute of Organic Chemistry, University of Saarland, Saarbrücken, Germany, <sup>4</sup>Pathology, Institute of Pathology, University of Tübingen, Germany.

**Background and aims:** 11-Keto-β-boswellic acid (KBA) has been shown to prevent insulinitis in the model of Multiple Low Dose-Streptozotocin (MLD-STZ) diabetic mice. Here in a second model of autoimmune diabetes which is the Non Obese Diabetic (NOD) mouse it should be tested whether or not KBA produces similar effects compared to the MLD-STZ diabetes.

**Materials and methods:** Female NOD mice 4 weeks of age (Charles River) were i.p. injected for 3 weeks with 7.5 mg/kg KBA. After 3 weeks of KBA-treatment, animals were killed and blood was collected for determination of glucose and cytokines (IL-1A, IL-1B, IL-2, IL-6, IFN-γ, TNF-α). Pancreases were isolated for histochemistry. Another group of mice was followed up for monitoring of blood glucose and body weight for 22 weeks. Cytokines were analyzed using Multi-Analyte ELISArray<sup>™</sup>. Lymphocytes infiltration into pancreatic islet cells and apoptosis were detected with anti-CD3 and anti-caspase 3 respectively. Blood glucose was evaluated with test strips (Accu-check aviva glucometer).

**Results:** In the seventh week of age there was infiltration of lymphocytes and appearance of apoptotic cells in pancreatic islets of all control mice. Cytokines in the blood showed no change at this time, but blood glucose was significantly decreased (106.5±4.6 vs. 77.3±5.4 mg/dl, P<0.05). From 6 animals treated with KBA 4 showed no infiltration of lymphocytes into pancreatic islets as well as no appearance of apoptotic islet cells in all while blood glucose levels did not change. Furthermore, there was no change of cytokines in comparison to control. After 12 weeks control group still exhibited decrease of blood glucose (71.7±2.9 mg/dl, P<0.05) and body weight was not increased compared to four weeks old animals (16.5±0.4 vs. 15.0±0.8). However, in KBA treated animals body weight increased (17.8±0.4 vs. 23.2±0.6, P<0.05) and blood glucose level was still normal (91.5±3.0 vs. 100.2±4.5 mg/dl). After the week 18, in 4 of 5 animals there was a sharp increase of blood glucose in the non treated animals, while on the other hand only 3 out of 6 KBA treated mice developed hyperglycemia.

**Conclusion:** Similar to recent results obtained in mice with MLD-STZ-diabetes, KBA reduced development of insulinitis and apoptosis of islet cells of NOD mice. In this period the hypoglycemia appearing in control NOD mice which may be due to insulin leakage from damaged β-cells. This could be prevented by KBA treatment. Moreover, KBA treatment of NOD mice allowed normal development of body weight over the period tested. Since so far KBA was effective in two different animal models of type 1 diabetes, the data are promising for clinical studies in autoimmune diabetes.

## PS 023 Functional beta cell mass in type 1 and type 2 diabetes

460

### BMI explains the major part of differences in beta cell function and insulin sensitivity between Japanese and Caucasians

M. Ohsugi<sup>1</sup>, H. Tanaka<sup>1</sup>, M. Pedersen<sup>2</sup>, J.B. Møller<sup>3</sup>, R.V. Overgaard<sup>3</sup>, J. Lyng<sup>3</sup>, K. Almind<sup>3</sup>, N.-M. Vasconcelos<sup>3</sup>, P. Poulsen<sup>3</sup>, C. Keller<sup>3</sup>, K. Ueki<sup>1</sup>, S.H. Ingwersen<sup>3</sup>, B.K. Pedersen<sup>2</sup>, T. Kadowaki<sup>1</sup>

<sup>1</sup>Department of Metabolic Diseases, University of Tokyo, Japan, <sup>2</sup>Centre of Inflammation and Metabolism, Department of Infectious Disease, Rigshospitalet, University of Copenhagen, Denmark, <sup>3</sup>Novo Nordisk A/S, Bagsvaerd, Denmark.

**Background and aims:** Ethnic differences in the pathophysiology of type 2 diabetes (T2D) have been the subject of several investigations. Japanese individuals are perceived to have higher insulin sensitivity and less ability to compensate for insulin resistance by increased beta-cell function compared to Caucasians. However, the data to support this are limited. We undertook a cross-sectional study in Japanese and Caucasians with the aim of investigating beta-cell function and insulin sensitivity and the contribution of demographic, genetic, biochemical and life-style related factors to differences found.

**Materials and methods:** The study comprised 120 Japanese and 150 Caucasians ranging from normal glucose tolerance (NGT) and impaired glucose tolerance (IGT) to T2D with similar distributions between high/low BMI in each of the glucose tolerance groups. BMI cut-off values were set in accordance with regional demographic differences. Beta cell function (HOMA-B, insulinogenic index and insulin secretion ratio) and insulin sensitivity (HOMA-IR and Matsuda index) were assessed from oral glucose tolerance tests and analysed by ANOVA.

**Results:** Mean glucose profiles were similar in Japanese and Caucasian NGT, IGT, and T2D subjects, respectively whereas insulin and C-peptide responses were lower in Japanese. Japanese were less insulin resistant than Caucasians and the beta-cell function was lower in Japanese compared to Caucasians. The disposition index - a measure of beta cell function relative to insulin resistance - was similar between Japanese and Caucasians in each glucose tolerance group. Among the covariates studied, BMI and other measures of body size, such as waist and weight, were major determinants of both insulin sensitivity and beta cell function. In this study, BMI was a design parameter and in order to quantify the role of BMI in explaining ethnic differences, endpoints were adjusted to the median BMI value for each glucose tolerance group. This was justified by similar linear relationships between individual endpoints and BMI values for the two ethnicities. Following BMI adjustment, the differences between Japanese and Caucasians were substantially reduced in all groups (shown for insulinogenic index in the figure). For all five indices, ethnic differences were no longer statistically significant for NGT and IGT participants.

**Conclusion:** We confirm that Japanese generally have higher insulin sensitivity and lower beta-cell function than do Caucasians. The major part of these differences can be explained by differences in body size (BMI).

### Beta cell area and function in human type 2 diabetes and the relationships with anti-diabetic therapy

L. Marselli, M. Suleiman, M. Bugliani, F. Syed, F. Scatena, D. Focosi, L.M. Mariotti, F. Filipponi, U. Boggi, P. Marchetti;

Department of Endocrinology and Metabolism, University of Pisa, Italy.

**Background and aims:** Type 2 diabetes (T2D) is characterized by reduced beta cell functional mass. To date little information is available on the direct properties of human islets in this disease. Aim of the present study was to evaluate the amount of beta cells and their ex vivo function in non-diabetic (ND) and T2D subjects, to be correlated with clinical parameters, including anti-diabetic therapy in T2D patients.

**Materials and methods:** Pancreases were obtained from 288 ND donors (age: 59±17 yrs; 154 males and 134 females; BMI: 25.2±3.7 kg/m<sup>2</sup>), and 45 T2D subjects (age: 69±9 yrs; 23 males and 22 females; BMI: 27.7±4.1 kg/m<sup>2</sup>; mean duration of diabetes: 8±6 yrs). Beta cell amount was evaluated by insulin immunostaining and morphometric analysis; isolated islets were prepared by enzymatic digestion and density gradient purification; insulin secretion was assessed basally and after stimulation with glucose and arginine.

**Results:** Insulin positive area (IPA) per islet was lower in T2D cases (56±18% vs 71±12%, p<0.01). Insulin release in response to glucose (stimulation index, SI: 1.6±0.7 vs 2.9±1.8, p<0.05) and arginine (1.7±0.5 vs 2.4±1.4, p<0.01) was also significantly reduced in islets of T2D subjects. In T2D no correlation was observed between IPA or SI values and age, BMI or duration of diabetes; in addition, IPA and SI were not correlated each other. Forty-three % T2D subjects were treated with diet (D) or D plus metformin (group D+M), 40% received sulfonylurea alone or in combination with M (group S), the remaining 17% were treated with insulin either associated with oral hypoglycemic agents or alone (group I). The three therapy groups did not differ in terms of age and BMI. IPA was not significantly different between D+M (47±18%), S (66±14%) and I (55±18%) groups. Glucose SI was higher in D+M (2.0±0.8, p<0.05, Bonferroni corrected) than S (1.4±0.4, p<0.05) and I (1.0±0.1, p<0.05) islets. No difference was observed between groups as for arginine SI.

**Conclusion:** These results confirm that islets of T2D subjects have reduced beta cell amount and function, which in our cohort were not significantly correlated with age, BMI, and duration of diabetes; the type of anti-diabetic therapy was not associated with the amount of islet beta cells, but rather with the residual beta cell glucose competence. Rescuing beta cell function thus appears to be a primary target of T2D therapy.

462

### Change in beta cell and alpha cell mass in Japanese obese individuals

K. Kou<sup>1</sup>, Y. Saisho<sup>1</sup>, T. Yamada<sup>2</sup>, H. Itoh<sup>1</sup>;

<sup>1</sup>Internal Medicine, Keio University School of Medicine, <sup>2</sup>Pathology, Keio University School of Medicine, Tokyo, Japan.

**Objective:** Both type 1 and type 2 diabetes are characterized by a deficit of β-cell mass. Thus to increase β-cell mass is an important strategy for the treatment of both types of diabetes. Although it has been reported that β-cell mass increases approximately 50% in response to obesity in Caucasian, there is limited data available as to β-cell mass in Asian population. Less degree of obesity with similar incidence of type 2 diabetes in Asian compared to Caucasian suggests less functional β-cell capacity in Asian. Therefore in this study we examined whether β-cell mass increases in Japanese obese individuals.

**Research design and methods:** We obtained autopsy pancreas from 30 lean (defined as BMI 23.5 or less) and 17 obese (defined as BMI 25 or more) Japanese adults aged from 20 to 60 years (age 47 ± 12 (mean ± SD) vs. 44 ± 12 years, p = 0.44, BMI 20.2 ± 1.3 vs. 27.2 ± 1.6, p < 0.0001, respectively). To be included, cases were required to have 1) had a full autopsy within 24 h of death, 2) pancreas tissue stored with adequate size and quality. Cases were excluded if 1) subjects had been diagnosed as diabetes or exposed to chronic glucocorticoid treatment, 2) pancreas tissue showed autolysis or any abnormal change such as pancreatitis. Pancreas tissues were stained for insulin or glucagon, and fractional β-cell area and α-cell area to the pancreas (%) were measured, respectively. β-cell and α-cell mass was also calculated as a product of fractional β-cell area and reference values of pancreas parenchymal mass. We also measured frequency of β-cell replication and apoptosis by immunohistochemistry for Ki-67 staining and ssDNA staining, respectively. β-cell neogenesis was evaluated by density of insulin positive duct cell. In addition, we measured β-cell size in each case.

**Results:** There was no increase in fractional  $\beta$ -cell area ( $1.6 \pm 0.9$  vs.  $1.1 \pm 0.8$  %,  $p = 0.05$ ) and fractional  $\alpha$ -cell area ( $1.1 \pm 0.8$  vs.  $0.9 \pm 0.7$  %,  $p = 0.29$ ) in the obese individuals compared with the lean individuals. These results did not change even when  $\beta$ -cell mass ( $0.74 \pm 0.40$  vs.  $0.54 \pm 0.39$  g,  $p = 0.11$ ) and  $\alpha$ -cell mass ( $0.48 \pm 0.26$  vs.  $0.43 \pm 0.31$  g,  $p = 0.52$ ) were used in the analysis. As a result,  $\alpha$ -cell area to  $\beta$ -cell area ratio was not changed in obesity ( $0.77 \pm 0.61$  vs.  $1.15 \pm 1.26$ ,  $p = 0.17$ ), while  $\alpha$ -cell area is significantly positively correlated with  $\beta$ -cell area ( $r = 0.44$ ,  $p = 0.002$ ). There was no significant difference in mean  $\beta$ -cell size between the groups ( $8.6 \pm 0.8$  vs.  $8.8 \pm 0.6$   $\mu\text{m}$ ,  $p = 0.33$ ). The frequency of  $\beta$ -cell apoptosis was very low in all cases and there was no difference in the frequency of  $\beta$ -cell apoptosis between the groups. There was no difference in the frequency of  $\beta$ -cell replication between the groups ( $0.039 \pm 0.045$  vs.  $0.043 \pm 0.041$  /islet,  $p = 0.77$ ), while the frequency of  $\beta$ -cell replication was positively correlated with fractional  $\beta$ -cell area ( $r = 0.48$ ,  $p = 0.001$ ). There was no difference in insulin positive ductal cell density between the groups ( $0.05 \pm 0.1$  vs.  $0.09 \pm 0.03$  /mm<sup>2</sup>,  $p = 0.14$ ).

**Conclusion:**  $\beta$ -cell mass was not increased in Japanese obese individuals. There was a positive correlation between fractional  $\beta$ -cell area and  $\beta$ -cell replication, suggesting that regulation of  $\beta$ -cell mass might be determined by  $\beta$ -cell replication in adult Japanese, which, however, may not be upregulated in obesity. Our findings suggest the possibility that  $\beta$ -cell regenerative capacity in Japanese may differ from Caucasian population. Comparison of islet morphology among different ethnics may provide insight into the mechanism of  $\beta$ -cell regeneration.

### The prevalence of endogenous insulin production in a cohort of adults with type 1 diabetes

R.A. Oram, M.H. Shepherd, M. Hudson, T. Sanders, S. Tiley, S. Hammersley, B. Shields, T.J. McDonald, B.A. Knight, R.E.J. Besser, A.T. Hattersley;  
Institute of Biomedical & Clinical Science, Exeter, UK.

**Background and aims:** The practical difficulty of serum C-peptide measurement means there are few community studies of endogenous insulin production in Type 1 Diabetes (T1D). We aimed to use urine C-peptide creatinine ratio (UCPCR) to quantify the prevalence and associated clinical features of insulin production in a cohort of adults with T1D. We also aimed to quantify how many with an initial diagnosis of T1D had an alternate diagnosis such as MODY or Type 2 Diabetes (T2D).

**Materials and methods:** 386 Subjects (180 male) were recruited to the UNITED project. All were on insulin from diagnosis, diagnosed <30 years, and current age <50 years. Insulin production was assessed using 2 hour post-prandial UCPCR. The presence of significant insulin production was assessed using a cut-off of 0.2 nmol/mmol. If UCPCR was >0.2 nmol/mmol then antibody testing for GAD and IA2 was performed. If GAD or IA2 antibodies were present then the diagnosis was assumed to be T1D, if they were not present then genetic testing was performed to rule out MODY. In patients with a negative genetic test for MODY a BMI cut off of 30 was applied before assuming the diagnosis was T1D.

**Results:** 345/386 (90%) had C-peptide detectable in the urine (UCPCR >0.01 nmol/mmol) 70/386 (18%) had a UCPCR >0.2 nmol/mmol. 35/70 patients with a UCPCR >0.2 nmol/mmol were antibody positive and assumed to have T1D. 9 of the remaining 35 were found to have MODY on genetic testing (8 HNF1A, 1 GCK and 1 HNF1B). 6 more patients were excluded from analysis with a BMI >30. Therefore a total of 15/386 (4%) of patients had an alternate diagnosis. The remaining group of 371 were assumed to have T1D. 55/371 (15%) had a UCPCR >0.2 nmol/mmol and 307/371 (83%) had UCPCR >0.01. 78% of patients (29/37) within 5 years of diagnosis had a UCPCR >0.2. 8% (27/334) of patient >5 years post diagnosis and 5% (8/186) >20 years post diagnosis had a UCPCR >0.2 nmol/mmol. Patients with UCPCR >0.2 had a lower 24 hour insulin dose ( $0.6$  v  $0.7$  u/Kg,  $p < 0.0001$ ) and shorter duration ( $5$  v  $21$  years,  $p < 0.0001$ ). Although there was no difference between HbA1c ( $8.8$  v  $8.6$   $p = 0.7$ ).

**Conclusion:** UCPCR allows screening of large populations of patients for residual insulin production. 18% of patients with an initial diagnosis of T1D were making significant amounts of insulin in this study. 4% of all patients were misdiagnosed and had MODY or T2D. In the refined T1D group 78% < 5 years and 8% >5 years post diagnosis had significant endogenous insulin. 5% of patients with T1D >20 years duration had significant endogenous insulin.

## 464

### Persistence of C-peptide secretion and impact on health in advanced type 1 diabetes

D.L. Faustman, L. Wang, S. Leung;  
Immunobiology Laboratory, Massachusetts General Hospital, Charlestown, USA.

**Background and aims:** In patients with longstanding disease, even modest beta-cell function is associated with a lower incidence of hypoglycemia, retinopathy and nephropathy compared to absent beta cell function when assessed using a standard C-peptide assay. This study examined the persistence of C-peptide secretion (a marker of insulin production and surviving beta cells) in the decades after type 1 diabetes onset and identified factors associated with preservation of beta-cell function in advanced disease.

**Materials and methods:** Using an ultrasensitive assay (lower detection limit: 1.5 pmol/L), we measured serum C-peptide levels in 182 human subjects with type 1 diabetes. Disease duration, age at onset, age, sex, and autoantibody titers were analyzed by regression analysis to determine their relationship to C-peptide production. A separate patient group (n=4) was serially studied for up to 20 weeks to examine C-peptide levels and beta cell functioning. Preliminary screening studies were also conducted to correlate remaining C-peptide with the prevention of hypoglycemic episodes.

**Results:** We report that the ultrasensitive assay detected C-peptide in 10% of individuals 31-40 years after disease onset; that patients with C-peptide levels as low as  $2.8 \pm 1.1$  pmol/L responded to hyperglycemia with increased C-peptide production, indicating intact beta cell functioning; that disease duration and level of zinc transporter 8 autoantibodies were significantly associated with C-peptide production; and that disease onset after age 40 was unexpectedly associated with low C-peptide production, despite shorter disease duration. New data will be presented on the status of low-level C-peptide secretion, assessed by ultrasensitive assay, as it relates to protection from hypoglycemia.

**Conclusion:** The ultrasensitive assay, 22x more sensitive than current standard assays, revealed that C-peptide production persists for decades after disease onset and remains functionally responsive in T1D. These findings suggest that patients with advanced disease, whose beta-cell function was thought to have long ceased, may benefit from interventions that preserve or stimulate beta cell function and should be more broadly included in clinical trials.

**Significance of lactoferrin autoantibodies in patients with type 1 diabetes**  
O.S. Derevyanko, T.V. Nikonova, E.V. Pekareva, A.V. Ilyin, O.M. Smirnova;  
Endocrinology Research Centre, Moscow, Russian Federation.

**Background and aims:** Histological analysis has demonstrated lymphocytic infiltration in endocrine and exocrine parts of pancreas in some patients with type 1 diabetes mellitus (T1DM). The aim of our study was to investigate the involvement of autoimmunity against the exocrine part of pancreas in T1DM patients and its association with other autoimmune diseases.

**Materials and methods:** 60 patients with T1DM and 20 healthy subjects (control group) were included in the study. None of them had any clinical symptoms of pancreatitis. The 1st group included 44 patients with only T1DM, the 2nd group - 16 patients with T1DM and autoimmune thyroiditis. Autoantibodies against lactoferrin (LACAb) were detected by using immunometric enzyme immunoassay. All subjects were tested for ICA, GADA, IA-2A, C-peptide, HbA1c.

**Results:** Significant difference was observed in frequency of LACAb occurrence between the study groups and control group ( $p < 0.05$ ). LACAb titer was significantly higher in patients of 1st and 2nd group than in control group ( $p < 0.05$ ). LACAb titer was 2,62 U/ml [2,02; 3,92] in 1st group; 3,31 U/ml [3,16; 3,56] in 2nd group and 1,87 U/ml [1,73; 2,31] in the control group. One of T1DM patients with the high titer of LACAb 8,89 U/ml also had celiac disease, another T1DM patient with the titer 6,64 U/ml had rheumatoid arthritis as well. No difference was found between 1st and 2nd groups ( $p = 0.11$ ). LACAb titer was significantly higher in patients with the duration of diabetes less than 5 years compared to other groups 4,02 [2,36; 8,56] ( $p < 0.05$ ). We also observed a trend to LACAb titer reduction with increasing of disease duration.

**Conclusion:** The study showed a high frequency of LACAb occurrence in patients with T1DM. These findings suggest the involvement of autoimmunity against the exocrine part of pancreas as well as against the endocrine part in some type 1 diabetic patients. These data may indicate the increased risk of chronic pancreatitis development in LACAb positive T1DM patients.

**Antibodies to beta cells antigens in cases of glucose metabolism disorders and obesity in children**

O.A. Budreiko, N.V. Shlyachova, L.D. Nikitina, S.O. Chumak, N.V. Filipova;  
State Institution "Institute of Children and Adolescents Health Care of National Academy of Medical Sciences", Kharkiv, Ukraine.

**Background and aims:** The presence of organ-specific antibodies against  $\beta$ -cells of pancreas is considered an important marker of their autoimmune destruction and predicts development of type 1 diabetes mellitus (DM1). However, the role of separate diabetogenic antibodies remains to date unclear in pathogenesis of type 2 diabetes mellitus (DM2) and other disorders of carbohydrate metabolism, especially in children and young people. Therefore, this study was aimed to investigate the production of antibodies against the most important diagnostic markers of autoimmune destruction of islet cells - antibodies against GAD (GADA) and tyrosine phosphatase autoantibodies (IA-2A), in children with impaired glucose metabolism (DM2, impaired glucose tolerance (IGT), impaired fasting glucose (IFG)), and insulin resistance (IR) against the background of obesity.

**Materials and methods:** A total of 125 children (65 boys and 60 girls) of age 7 to 18 years with impaired glucose metabolism (with IGT -  $n = 19$ , IFG -  $n = 20$ , with DM2 -  $n = 14$  and DM1 -  $n = 28$ ), obesity ( $n = 44$ , including those with IR -  $n = 22$ , and without IR -  $n = 22$ ) as well as 36 of their healthy peers were examined. For identification of carbohydrate metabolism disorders a OGTT was carried out according to WHO criteria, to determine the presence of glycemia, glycosuria, HbA1c. Determined was a level in serum of cytokines TNF $\alpha$ , IL1 $\beta$ , IL2, IL6 and IL10 (ELISA), of GADA and IA-2A, of C-peptide, of immunoreactive insulin (RIA). The study has been reviewed by the Local Ethics Committee and has been performed in accordance with the ethical standards laid down in the Helsinki Declaration.

**Results:** It was determined that some children with obesity (11%) display increased levels of GADA and/or IA-2A, but average indexes for the group

were  $1,02 \pm 0,10$  U/ml and  $0,78 \pm 0,06$  U/ml and did not differ significantly from those in the control group ( $0,80 \pm 0,09$  U/ml and  $0,45 \pm 0,02$  U/ml). In patients with DM1 levels of GADA ( $14,80 \pm 1,10$  U/ml) and IA-2A ( $11,36 \pm 0,87$  U/ml) were significantly increased ( $p < 0.01$ ), while in patients with DM2 they were increased as well, but to a lesser extent ( $8,77 \pm 0,19$  U/ml and  $7,43 \pm 0,62$  U/ml, respectively,  $p < 0.05$ ). Among other disorders of carbohydrate metabolism only patients with IGT displayed increased level of GADA ( $5,35 \pm 0,24$  U/ml,  $p < 0.05$ ) but not against IA-2A ( $0,84 \pm 0,11$  U/ml). Connection of insulinosecretion reduction with presence of antibodies against  $\beta$ -cells of pancreas has been proved only for patients with DM1, while children with obesity did not display differences in level of C-peptide dependent on presence of GADA and IA-2A. For patients with obesity the correlation is established between the level of antibodies against  $\beta$ -cells in blood and the content of separate cytokines: between GADA and IL6 ( $r = 0,36$ ,  $p < 0.05$ ), GADA and TNF $\alpha$  ( $r = 0,45$ ,  $p < 0.05$ ), GADA and IL-10 ( $r = 0,34$ ,  $p < 0.05$ ), IA-2A and IL6 ( $r = 0,29$ ,  $p < 0.05$ ).

**Conclusion:** A number of children with obesity, DM2 and IGT displayed signs of autoimmune aggression against pancreatic islets with involvement of cytokines in the pathological process. Although identified disorders were not accompanied by a pathological reduction of insulinosecretion in patients, the potential risk of severe carbohydrate metabolism disorders requires further study of the production of antibodies against antigens of  $\beta$ -cells in children with obesity, especially in combination with carbohydrate metabolism disorders.

**Coxsackievirus initiates strong immune response and death of beta cells**

E. Domsgen<sup>1</sup>, F. Paroni<sup>1</sup>, J. Kerr-Conte<sup>2</sup>, A. Dotzauer<sup>1</sup>, K. Maedler<sup>1</sup>;

<sup>1</sup>Centre for Biomolecular Interactions, University of Bremen, Germany,

<sup>2</sup>University of Lille, France.

**Background and aims:** Group B Coxsackievirus (CVB) infection of  $\beta$ -cells is associated with diabetes and induction of inflammation mediates  $\beta$ -cell destruction. Intra-islet viral particles were detected in patients with T1DM and T2DM, but the mechanisms of a correlation between virus infection and diabetes progression are poorly understood. In this study we asked the question, to which pattern recognition receptors (PRR) viral RNAs bind and which intracellular signals are induced to stimulate an inflammatory stage in human islets.

**Materials and methods:** Isolated human islets were infected with two different CVB serotypes, CVB3 and 4. Replication of CVB was confirmed by immunostaining of viral protein 1 (VP1) and titration of islet lysate. CXCL10 secretion from the islets was measured by ELISA; CXCL10, IFN $\beta$ , IFN $\gamma$ , IL-1 $\beta$ , TNF $\alpha$ , IL-6, MCP1, IL-8, RIG-I, TLR3, TLR7, MDA-5 and PKR mRNA production by quantitative RT-PCR and  $\beta$ -cell apoptosis by double-staining for the TUNEL assay and insulin. Islet protein expression and phosphorylation were analyzed by western blot. Binding of CVB ssRNA and dsRNA was investigated by immunoprecipitation-RT-PCR coupled assays.

**Results:** Isolated human islets were permissive for CVB, and upon infection,  $\beta$ -cell apoptosis was 7-fold increased. GSIS of infected islets showed impaired function at 72h post infection. The chemokine CXCL10, a known  $\beta$ -cell apoptosis inducer, was secreted upon infection, indicating induction of immune response. Immunoprecipitation-RT-PCR coupled assays demonstrated that viral CVB3 and 4 ssRNA bound to TLR3 and CVB4 ssRNA additionally to TLR7. Both CVB 3 and 4 dsRNA bound to protein kinase R (PKR), induced its phosphorylation. Lack of PKR in  $\beta$ -cells further increased apoptosis, suggesting that PKR protects the  $\beta$ -cell from virus effects. In contrast, retinoic acid inducible gene I (RIG-I) and Melanoma differentiation associated protein 5 (MDA-5) binding to CVB-dsRNA occurred secondarily in a later stage during infection. TLR3 sensing resulted in increased mRNA levels of the cytokines/chemokines CXCL10, IFN $\beta$ , IL-1 $\beta$ , TNF $\alpha$ , IL-6, MCP1 and IL-8 in the infected islets, while IFN $\gamma$  remained unchanged. CXCL10 was the highest induced factor (15-fold increase in mRNA,  $p < 0.001$ ), compared to uninfected islets. mRNA levels of TLR3, RIG-I, MDA5 and PKR were increased during infection. Immunostaining of TLR3 showed colocalisation with  $\beta$ -cells, while TLR7 was mainly expressed in  $\alpha$ -cells.  $\alpha$ - and  $\beta$ -cell specific co-staining with VP1 showed that CVB3 and 4 infected mainly the  $\beta$ -cells (60%  $\beta$ -cells were VP1 positive). While CVB3 infection led to VP1 expression in 5% of the  $\alpha$ -cells, CB4 showed 10% VP1/glucagon co-staining, suggesting an additional tropism of CVB4 for  $\alpha$ -cells. This did not result in differences in  $\alpha$ -cell survival. Both viruses induced apoptosis in  $\beta$ -cells.

**Conclusion:** Our data show that CBV infections have a direct deleterious effect on  $\beta$ -cell survival, resulting from virus-induced apoptosis and activation

of pro-inflammatory cytokines and chemokines as well as upregulation of PRR. CVB3 and 4 showed high tropism to TLR3 expressing  $\beta$ -cells, but CVB4 also bound to TLR7 expressed in  $\alpha$ -cells showing that virus sensing of TLR3 and 7 is strain and cell type specific. With our present data we provide novel targets towards protecting the  $\beta$ -cell during virus infection.

### Beta cell expression of enteroviral receptor CAR and islet inflammation in human type 1 diabetes

I. Spagnuolo<sup>1,2</sup>, A. Patti<sup>1,2</sup>, G. Sebastiani<sup>1,2</sup>, F.A. Grieco<sup>1,2</sup>, F. Dotta<sup>1,2</sup>;

<sup>1</sup>Diabetes Unit, Department of Internal Medicine, Endocrine and Metabolic Sciences and Biochemistry, University of Siena, <sup>2</sup>Fondazione Umberto Di Mario ONLUS - Toscana Life Science, Siena, Italy.

**Background and aims:** Type 1 diabetes mellitus (T1D) is a chronic autoimmune disease in which pancreatic beta cells are selectively destroyed by an autoimmune process. The onset is caused by the interaction of genetic, immunological and environmental factors. Among the environmental factors potentially involved in the T1D etiology, viral infections play a key role. Previous studies have demonstrated signs of enteroviral infection in pancreatic islets, and most intriguingly in beta cells, from recent-onset T1D patients. Moreover it has been suggested that Coxsackie B4 virus (CVB4) directly trigger beta-cell destruction, suggesting a link between enteroviral infections and T1D. The susceptibility to viral infections is caused by viral variant and by the nature of infection, while the specific tropism of viruses is modulated by the local expression of cellular receptors, such as hCAR (coxsackievirus and adenovirus receptor). We here aimed at characterizing islet inflammation and hCAR islet expression in human type 1 diabetes.

**Materials and methods:** We studied pancreatic specimens obtained from 4 recent onset T1D, from 2 long standing (disease duration: 7 and 14 years) T1D and from 10 non-diabetic organ donors. Formalin-fixed and paraffin embedded pancreatic sections were used in immunohistochemical experiments for the presence of proinflammatory molecules (CXCL10, CCL2, Fas) as well as of viral receptor hCAR. In addition, double immunofluorescence with confocal microscopy analysis was utilized for the identification islet cell subset(s) expressing the molecule of interest (i.e. alpha-, beta- and delta cells identified by anti-glucagon, anti-insulin and anti-somatostatin antibodies respectively).

**Results:** In T1D pancreata, insulitis was present in 44% of islets and was characterized by CD3 expressing T-cells and natural killer cells. Ongoing islet inflammation was detected in all T1D cases, but not in control donors, with in situ detection of CXCL10, Fas and of CCL2; interestingly, this latter chemokine showed a remarkable beta-cell specific expression. Viral receptor hCAR was expressed both in T1D and in control donors mainly in islet cells and, of note, almost exclusively at beta cell level, suggesting the existence of a differential distribution of enterovirus receptors among islet cell subsets, possibly influencing the susceptibility of these cells to enteroviral infection. Intriguingly, the only rare alpha cells expressing hCAR were single cells located outside islet structures and sparse throughout the exocrine tissue.

**Conclusion:** In conclusion, we have shown that islet inflammation can be detected at disease onset, persists years after T1D diagnosis and is characterized by proinflammatory molecules and by a beta cell specific expression chemokine CCL2. In addition, we uncovered the beta-cell expression of enteroviral receptor hCAR, which may represent a mechanism responsible for the beta cell tropism observed in the case of some enteroviruses.

### ISG15 detected in beta cells of fulminant type 1 diabetes indicates anti-apoptotic effect in MIN6 cells

A. Yoshikawa, A. Imagawa, S. Nakata, S. Uno, K. Fukui, Y. Kuroda, Y. Miyata, Y. Sato, T.-A. Matsuoka, H. Iwahashi, I. Shimomura;  
Metabolic Medicine, Graduate School of Medicine, Osaka University, Suita, Japan.

**Background and aims:** Involvement of viral infections has been suggested in the pathogenesis of fulminant type 1 diabetes. We focused on ISG15 located in the downstream of type I interferon signaling and investigated its expression in pancreatic autopsy specimens and its role in mouse beta cell line MIN6.

**Materials and methods:** We examined pancreas autopsy specimens from three patients with fulminant type 1 diabetes who had died just after the onset of overt diabetes. To visualize the pancreatic beta cells, alpha cells and ISG15, sections were stained using the indirect immunohistochemical technique. Recombinant adenoviruses expressing ISG15 and short hairpin RNA against ISG15 were prepared using the pAdEasy system. The expression of ISG15 mRNA was assessed by real-time quantitative RT-PCR and the production of ISG15 protein was detected by western blots in MIN6 cells. To assess the cell apoptosis, Caspase 3/7 activity assay was performed with Caspase-Glo 3/7 assay Systems.

**Results:** Immunohistochemical analysis revealed that the expression of ISG15 was detected in islets of all three patients and also in exocrine pancreas of one patient with fulminant type 1 diabetes, but neither in islets nor in exocrine pancreas of all three control subjects. By double staining for ISG15 and islet hormones, ISG15 was expressed in insulin-positive cells but not in glucagon-positive cells. Neither ISG15 mRNA nor protein was detected in MIN6 cells without treatment of IFN alpha. IFN alpha upregulated ISG15 mRNA and protein production in MIN6 cells at dose dependent manner. Expression of ISG15 mRNA and protein production was increased by treatment of Ad-ISG15, but not by treatment of Ad-GFP. After incubation with Ad-GFP, then exposure to IFN gamma plus IL-1beta result in an approximate 3.3-fold increase in Caspase 3/7 activity. Treatment with Ad-ISG15 in addition to IFN gamma and IL-1beta decreased caspase 3/7 activity by 36.4% ( $P < 0.0001$ ). After incubation with Ad-GFP, then exposure to TNF alpha result in an approximate 3.0-fold increase in Caspase 3/7 activity. Treatment with Ad-ISG15 in addition to TNF alpha decreased caspase 3/7 activity by 34.4% ( $P = 0.0004$ ). On the other hand, expression of ISG15 mRNA and protein production was decreased by treatment of Ad-shISG15. After incubation with Ad-GFP, then exposure to IFN gamma and IL-1beta and IFN alpha result in an approximate 2.2-fold increase in Caspase 3/7 activity. Treatment with Ad-shISG15 increased caspase 3/7 activity by 32.3% ( $P = 0.0002$ ). After incubation with Ad-GFP, then exposure to TNF alpha and IFN alpha result in an approximate 3.8-fold increase in Caspase 3/7 activity. Treatment with Ad-shISG15 increased caspase 3/7 activity by 21.4%, but not significant ( $P = 0.46$ ). Those results indicate that apoptotic effect of inflammatory cytokines decreased by the addition of and increased by the deletion of ISG15.

**Conclusion:** ISG15 was expressed in pancreatic beta cells in fulminant type 1 diabetes and anti-apoptotic effect of ISG 15 was observed in MIN6 cells, suggesting a possible therapeutic approach by the induction of ISG15 in fulminant type 1 diabetes.

### St. John's Wort and hyperforin inhibit multiple phosphorylation steps of cytokine signalling in beta cells and modulate functional, inflammatory and apoptotic gene expression

P. Masiello<sup>1</sup>, P. Beffy<sup>2</sup>, M. Novelli<sup>1</sup>, S. Porozov<sup>1</sup>, A. Sgarbossa<sup>3</sup>, M. Masini<sup>1</sup>, V. De Tata<sup>1</sup>, L. Martino<sup>1</sup>, A. Pippa<sup>4</sup>, M. Menegazzi<sup>3</sup>;

<sup>1</sup>Dip. Patologia Sperimentale, University of Pisa, <sup>2</sup>Istituto di Fisiologia Clinica, CNR, Pisa, <sup>3</sup>Dip. Scienze della Vita e della Riproduzione, University of Verona, <sup>4</sup>Sant'Anna School of Advanced Studies, Pisa, Italy.

**Background and aims:** Cytokines released by mononuclear cells infiltrating the islets of Langerhans during an autoimmune attack are considered responsible for the  $\beta$ -cell destruction leading to type 1 diabetes, through STAT-1 and NF- $\kappa$ B activation and consequent expression of deleterious target genes. We have previously shown that the extract of Hypericum perforatum (St. John's wort, SJW) and its phloroglucinol component hyperforin (HPF), are potent inhibitors of cytokine-induced STAT-1 and NF- $\kappa$ B activation in  $\beta$ -cells and prevent dysfunction and apoptosis in INS-1E  $\beta$ -cell line, as well as in rat and human islets. Aims of this study were: a) to further clarify the mechanism of the regulatory activity of SJW and HPF on cytokine signaling pathways in INS-1E cells; b) to assess their ability to counteract the cytokine-driven changes in the expression of STAT-1 and NF- $\kappa$ B target genes involved in  $\beta$ -cell function, inflammatory response and apoptosis regulation.

**Materials and methods:** INS-1E cells, exposed to mixtures of IFN- $\gamma$ , IL-1 $\beta$  and TNF- $\alpha$  for various time periods with/without SJW extract (1-2  $\mu$ g/ml) or HPF (1-2  $\mu$ mol/l), were used for RT-qPCR gene expression analysis and assessment of the phosphorylation state of various components of STAT-1, NF- $\kappa$ B and MAPK pathways by western blotting. STAT-1 and NF- $\kappa$ B activation was also evaluated by EMSA on nuclear extracts.

**Results:** Cytokine-induced STAT-1 phosphorylation in both tyrosine and serine residues (2-3-fold increase vs. controls) was significantly hindered

by SJW or HPF in a dose-dependent manner. These compounds prevented NF- $\kappa$ B activation by suppressing phosphorylation of the p65 subunit and the inhibitory subunit I $\kappa$ B activating kinase (IKK). Furthermore, MAPK pathway was also modulated by the vegetal compounds through dose-dependent partial or total restriction of ERK1/2, p38 MAPK and JNK cytokine-induced phosphorylations. Inhibition of DNA binding of STAT-1 and NF- $\kappa$ B in the presence of SJW or HPF was confirmed by EMSA. Expressions of a number of  $\beta$ -cell functional genes, such as PDX-1, GLUT-2 and FOXO1, were down-regulated by 60–80% ( $p < 0.05$  vs. controls) upon cytokine treatment and restored in the presence of SJW and HPF, while expressions of insulin, glucokinase, MAFA, PAX-6 genes were less affected. A remarkable induction ( $>10$ -fold vs. controls) of iNOS and other pro-inflammatory genes (CXCL9, CXCL10, COX-2, ICAM-1, MHC-2 trans-activator) was elicited by cytokines in INS-1E cells and significantly reduced or totally abolished by vegetal compounds in a dose-dependent fashion. SJW and HPF were able to partially correct the cytokine-induced unbalance between anti- and pro-apoptotic factors, mainly by preventing down-regulation of anti-apoptotic members of BCL-2 family.

**Conclusion:** We provide evidence that SJW extract and hyperforin exert their protective effects against cytokine-induced  $\beta$ -cell damage by inhibiting multiple phosphorylation steps along the STAT-1, NF- $\kappa$ B and MAPK signaling pathways and modulating target gene expression. Thus, SJW components represent novel promising pharmacological tools for prevention or limitation of  $\beta$ -cell loss in type 1 diabetes.

## 471

### IFN- $\lambda$ elicits an antiviral state and protects human islets from coxsackievirus infection

M. Flodström-Tullberg, K. Lind;

Center for Infectious Medicine, Dept. of Medicine HS, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Infections with enteroviruses such as Coxsackie B viruses (CVB) have been associated with the development of type 1 diabetes (T1D). CVBs infect human islets in vitro and enterovirus has been found in islet remnants of T1D patients. How the host antiviral response regulates human islet permissiveness to infection is not fully understood. We have previously shown that type I and II interferons (IFNs) induce an antiviral state in human islets, lowering the islets' permissiveness to CVB infection. Type III IFNs (IFN $\lambda$ 1/IL29, IFN $\lambda$ 2/IL28A, and IFN $\lambda$ 3/IL28B) belong to a recently identified novel group of IFNs. They are produced in response to some viruses and activate antiviral defence in responsive cells. IFN $\lambda$ s bind to a receptor complex consisting of IL-10R2 and IL-28R $\alpha$ . The former receptor unit is ubiquitously expressed, while the latter shows a restricted tissue distribution. We recently observed that CVB infected human islets express IFN $\lambda$ s (unpublished observation). However, whether human islets respond to IFN $\lambda$ s remains unknown. Moreover, whether IFN $\lambda$ s prevent CVB replication has not been studied in any type of cell. Here, we investigated whether human islets express the receptor for IFN $\lambda$ s and respond to IFN $\lambda$  stimulation. Importantly, we also determined whether IFN $\lambda$ s protect human islets from CVB infection.

**Materials and methods:** The expression of IFN $\lambda$  receptor subunits and the response to IFN $\lambda$  exposure were analysed in human islets obtained from The Nordic Network for Clinical Islet Transplantation using Real-time (RT)-PCR or PCRarray (Qiagen). RNA from human peripheral blood mononuclear cells (PBMC) and hepatocyte cell lines were used as positive controls for IFN $\lambda$  receptor expression. In separate experiments, human islets were pre-treated with IFN $\lambda$ 1 (100 ng/ul) or IFN $\lambda$ 2 (100 ng/ul) for 24h and then infected with  $4 \times 10^4$  PFU/ml of Coxsackievirus B3 (CVB3). Viral titers in supernatants were assessed using a standard plaque assay technique.

**Results:** We demonstrate that human islets express mRNA encoding the IFN $\lambda$  receptor subunits IL-10R2 and IL-28R $\alpha$  at similar levels as human PBMCs. We also show that IFN $\lambda$ s induce the mRNA expression of several genes involved in the antiviral state (e.g. MxA, OAS) as well as pattern recognition receptors (e.g. IFIH1, RIG-I and TLR3) in human islets. Finally, we demonstrate that CVB3 replicates to significantly lower titers in IFN $\lambda$  treated human islets compared to untreated islets ( $p < 0.01$  vs. infected islets that were mock-treated).

**Conclusion:** Our results clearly suggest that human islets express IFN $\lambda$  receptors and respond to IFN $\lambda$  treatment by upregulating genes involved in antiviral defense and recognition of RNA viruses. By showing that CVB3 replication is perturbed in IFN $\lambda$  treated human islets we for the first time demonstrate that IFN $\lambda$  limits CVB replication in primary human cells. Col-

lectively, our results strongly support an important role for IFN $\lambda$ s in regulating human islet permissiveness to CVB infection. Thus, IFN $\lambda$ s may contribute to reduced tissue damage and promote host and beta cell survival upon an enterovirus infection.

## PS 025 Clinical immunology: immune markers in type 1 diabetes

472

### Cytokine-producing function of peripheral blood cells in the patients with type 1 diabetes mellitus

E.A. Repina<sup>1</sup>, E.N. Stepanova<sup>2</sup>;<sup>1</sup>Laboratory of Immunology and Genetics, Endocrinological Research Centre, Moscow, <sup>2</sup>Chair of Immunology, Russian Medical Academy of Postgraduate Education, Moscow, Russian Federation.

**Background and aims:** To investigate an influence of polyclonal activator - phytohemagglutinin and insulin upon cytokine-producing function of peripheral blood cells in the patients with type 1 diabetes mellitus.

**Materials and methods:** 25 type 1 diabetes mellitus patients were examined. They were divided into the following two groups: patients with duration of type 1 diabetes mellitus under 10 years (group 1) and patients with duration of type 1 diabetes mellitus more than 10 years (group 2). Mononuclear leukocytes were isolated by centrifugation in the ficoll-verographin density gradient. The cells thus obtained were resuspended in the complete nutrient medium reducing their concentration to  $2.0 \times 10^6$ /ml. Phytohemagglutinin (PHA-P, Sigma) (10 mcg/ml) and insulin (insulin human, Sigma) (10 mcg/ml) were added to the samples to stimulate mononuclear leukocytes; cell suspensions were further incubated for 36 hours. Initial, PHA-induced and insulin-induced levels of interleukin-1 (IL-1), IL-2, IL-4, IL-6, IL-8, IL-10, IL-12, gamma interferon (IFN- $\gamma$ ) and tumor necrosis factor alpha (TNF- $\alpha$ ) in supernatants of cell cultures were measured by solid phase immunoassay at 450 nm. Results were compared with clinical characteristics of the patients. There were 3 males and 5 females in group 1, 5 males and 12 females in group 2. Median age, diabetes mellitus duration, HbA1c in group 1 and group 2 were respectively 27 years, 3 years, 7.2 % and 38 years, 23 years, 10.3 %. Intensities of microvascular complications (diabetic retinopathy and diabetic nephropathy) were higher in the group 2. 3 patients (37.5 %) from group 1 had diabetic retinopathy on the basic stage and 8 patients (47 %) from group 2 had diabetic retinopathy on the last stage. Only 1 patient from group 1 had diabetic nephropathy on microalbuminuria stage and 7 patients from group 2 (41%) had diabetic nephropathy on proteinuria stage and on the stage of renal failor.

**Results:** Basal and PHA-induced production of IL-2, IL-4, IL-10, IL-12 were significantly higher in group 1 (0.83/7.8; 3.7/20.3; 7.35/58.7; 0.8/5.3) in comparison with group 2 (0.35/6.3; 2.3/13.5; 3.6/27.8; 0.3/1.7) ( $p=0.026/p=0.03$ ;  $p=0.05/p=0.03$ ;  $p=0.01/p=0.027$  and  $p=0.019/p=0.001$ ). At the same time, basal and PHA-induced levels of IL-1, IFN- $\gamma$  and TNF- $\alpha$  were significantly higher in group 2. These markers had significant positive correlation with microvascular complications (diabetic retinopathy and diabetic nephropathy) ( $R=0.78$   $p=0.043$ ;  $R=0.7$   $p=0.05$ ;  $R=0.67$   $p=0.04$  and  $R=0.72$   $p=0.043$ ;  $R=0.64$   $p=0.032$ ;  $R=0.64$   $p=0.05$ ).

**Conclusion:** The cytokine production ratio of stimulated versus resting cells may be used as a reliable predictor of disease severity in type 1 diabetic patients and microvascular complications in type 1 diabetes mellitus.

473

### CD4+ T cell proliferation responses after wheat polypeptide stimulation in children at different stages of type 1 diabetes autoimmunity

S. Hamari<sup>1</sup>, T. Kirveskoski<sup>1</sup>, V. Glumoff<sup>2</sup>, O. Simell<sup>3</sup>, M. Knip<sup>4</sup>, J. Ilonen<sup>5</sup>, R. Veijola<sup>1</sup>;<sup>1</sup>Department of Pediatrics, University of Oulu, <sup>2</sup>Department of Medical Microbiology, University of Oulu, <sup>3</sup>Department of Pediatrics, University of Turku, <sup>4</sup>Institute of Clinical Medicine, University of Helsinki, <sup>5</sup>Immunogenetics Laboratory, University of Turku, Finland.

**Background and aims:** Recent evidence suggests that immune reactivity of CD4+ lymphocytes is increased after *in vitro* wheat protein stimulation in patients with type 1 diabetes (T1D) of several years' duration. The aim of this study was to evaluate if there is any difference in T-cell responses after *in vitro* stimulation with different wheat polypeptides in recently seroconverted children and in children with newly-diagnosed type 1 diabetes compared to healthy controls.

**Materials and methods:** Peripheral blood mononuclear cells (PBMCs) were isolated 3-6 months after seroconversion for beta-cell specific autoantibodies from 34 subjects aged 1-15 years and 30 control subjects. In the second study

group the PBMCs were isolated 5-12 days after the diagnosis of T1D from 52 subjects aged 1-15 years and 51 control subjects. The control subjects of both groups were age-, sex- and sampling date matched healthy and autoantibody negative children carrying HLA-DQB1 risk associated genotypes. All study subjects were negative for tissue transglutaminase antibodies. Carboxy-fluorescein succinimidyl ester (CFSE) based T-cell proliferation assay was performed from freshly ( $< 8$  hours) isolated PBMCs and the proliferation responses were analyzed after 7 days *in vitro* antigen (tetanus toxoid, gliadin, gluten, whole wheat) stimulation. The positive proliferation response was defined as a cell division index (CDI) of at least 2.0 and the relative amount of proliferated CD4+ T-cells at least 0.5% from the parent gate. Only subjects with a positive tetanus toxoid response were included in the analysis.

**Results:** The frequencies of positive *in vitro* T cell responses for all three wheat proteins were similar between recently seroconverted children and controls (gliadin 73.5% vs. 73.3%;  $p=1.000$ , gluten 85.3% vs. 83.3%;  $p=1.000$  and whole wheat 23.5% vs. 26.7%;  $p=0.781$ ). In children with newly-diagnosed T1D the proportion of positive responses after *in vitro* gliadin stimulation was clearly decreased when compared to healthy controls (48.1% vs. 76.5%;  $p=0.004$ ), and a similar trend was seen for gluten and whole wheat responses (gluten 71.2% vs. 84.3%;  $p=0.155$  and whole wheat 15.4% vs. 25.5%;  $p=0.230$ ). No statistically significant differences were observed in the strength of positive responses (median CDI values) between the study and control groups.

**Conclusion:** Positive T-cell immune responses for wheat-based antigens are common in children. The frequencies of positive proliferation responses for gliadin, gluten and whole wheat were similar between children who had recently seroconverted positive for beta-cell specific autoantibodies and their controls. Decreased frequency of positive *in vitro* gliadin responses were observed in children with newly-diagnosed type 1 diabetes.

### Study of the insulin receptor (CD220) expression in peripheral immune cells of patients with type 1 diabetes

S.A. Paschou<sup>1</sup>, A. Petsiou<sup>2</sup>, G. Vartholomatos<sup>2</sup>, N. Kolaitis<sup>2</sup>, E. Giotaki<sup>3</sup>, A. Tsatsoulis<sup>1</sup>, G.K. Papadopoulos<sup>4</sup>;<sup>1</sup>Department of Endocrinology, Medical School, University of Ioannina,<sup>2</sup>Unit of Molecular Biology, Laboratory of Haematology, University Hospitalof Ioannina, <sup>3</sup>Department of Nursing, Epirus Institute of Technology,Ioannina, <sup>4</sup>Laboratory of Biochemistry and Biophysics, Epirus Institute of Technology, Arta, Greece.

**Background and aims:** Insulin receptors are essentially ubiquitous, yet scant attention has been paid to the possible actions of insulin on the immune system either in health or in an insulinopenic state such as type 1 diabetes. The aim of our study was to investigate the membrane expression of insulin receptor (CD220) in three very important categories of peripheral immune cells, T effector cells (Teff, CD4<sup>+</sup>CD25<sup>+</sup>), T regulatory cells (Tregs, CD4<sup>dim</sup>CD25<sup>high</sup>FOXP3<sup>high</sup>CD127<sup>low</sup>) and monocytes, of patients with type 1 diabetes in comparison with healthy controls.

**Materials and methods:** Peripheral blood from 39 patients with type 1 diabetes (13 newly-diagnosed ones (nd: 9M/4F, ages  $12.5 \pm 9.4$  years) and 26 long standing ones (ls: 12 M/14F, ages  $26.7 \pm 9.2$  years, with mean disease duration of  $11.6 \pm 7.4$  years), and 32 healthy controls (c) with no first or second degree relatives suffering from any autoimmune disease (13M/19F, ages  $25.3 \pm 11$  years) was analysed by triple colour flow cytometry for the membrane expression of insulin receptor (CD220) in Teff, Tregs and monocytes (without any Ficoll-paque mononuclear cell isolation).

**Results:** Insulin receptor is clearly expressed in the membrane of Teff (%  $1.65 \pm 4.38$ , MFI (Mean Fluorescence Intensity - number of molecules per cell)  $62.63 \pm 81.32$ ), Tregs (%  $9.30 \pm 25.15$ , MFI  $81.87 \pm 169.35$ ) and monocytes (%  $17.56 \pm 28.14$ , MFI  $486.27 \pm 1,354.80$ ) of healthy controls with a clear trend of higher levels in monocytes and Tregs than Teff ( $p = 0.006$  &  $p = 0.093$ ). The expression of insulin receptor in patients with type 1 diabetes in Teff (nd: %  $1.95 \pm 5.05$ , MFI  $96.95 \pm 180.34$ , ls: %  $0.37 \pm 0.64$ , MFI  $68.63 \pm 73.85$ ) and Tregs (nd: %  $3.88 \pm 7.90$ , MFI  $51.23 \pm 95.41$ , ls: %  $1.77 \pm 2.58$ , MFI  $185.7 \pm 455.24$ ) tends to be lower than in healthy controls, but without statistical significance (in all comparisons  $p > 0.05$ ). In the case of monocytes, the difference in the frequency of insulin receptor between controls and diabetic patients is substantial and statistically significant (nd: %  $2.17 \pm 4.94$ , MFI  $316.23 \pm 460.27$ , ls: %  $0.24 \pm 0.37$ , MFI  $507.31 \pm 1,651.11$ ,  $p = 0.015$  &  $p = 0.006$ ), altering the pattern of its expression (Monocytes > Tregs > Teff) that we meet in healthy controls.

**Conclusion:** The lower frequency of insulin receptor expression in monocytes of patients with type 1 diabetes may affect the functionality of these important immune cells, especially in combination with the low levels of insulin in the immediate prediabetes phase, and can be one of the reasons for impaired suppression of the immune response in these patients.

## 475

### CXCR3<sup>+</sup>, CCR4<sup>+</sup> T memory cells and chemokine levels: comparison between recent onset type 1 diabetics and nondiabetic first degree relatives

T. Milicic<sup>1</sup>, N.M. Lalic<sup>1</sup>, A. Jotic<sup>1</sup>, I. Markovic<sup>2</sup>, M. Zamaklar<sup>1</sup>, K. Lalic<sup>1</sup>, L. Lukic<sup>1</sup>, N. Rajkovic<sup>1</sup>, M. Macetic<sup>1</sup>, J. Seferovic<sup>1</sup>;

<sup>1</sup>Clinical Center of Serbia, Clinic for Endocrinology, <sup>2</sup>Institute for Biochemistry, Belgrade, Serbia.

**Background and aims:** It has been previously suggested that chemokine receptors CXCR3 and CCR4, and its ligands, interferon- $\gamma$  inducible chemokine (IP-10) and thymus- and activation-regulated chemokine (TARC), are associated with Th1 and Th2 memory cell subsets respectively, and have important role in the initial phase of Type 1 diabetes (T1D). However, the changes in CXCR3<sup>+</sup> and CCR4<sup>+</sup> subsets of the T memory cells as well as in chemokine levels, IP-10 and TARC, in recent onset T1D and their nondiabetic first-degree relatives (FDRs), have not yet been elucidated. Therefore, the aim of this study was to analyze: (a) the percentage of CXCR3<sup>+</sup> (Th1 associated) and CCR4<sup>+</sup> (Th2 associated) subsets of T memory cells (b) chemokine levels IP-10 (Th1 associated) and TARC (Th2 associated), in peripheral blood in 27 recent-onset T1D patients in insulin-requiring state (IRS) at the onset (group A), 16 T1D patients in the state of clinical remission (CR) (group B), 43 nondiabetic FDRs (group C), as well as in 22 healthy, age-matched control subjects (group D).

**Materials and methods:** T1D was diagnosed in accordance to WHO criteria. The CR was defined as optimal metabolic control without insulin lasting >30 days. The percentages of CXCR3<sup>+</sup> and CCR4<sup>+</sup> T memory cell subsets were analyzed in peripheral blood by using four-color immunofluorescence staining and flowcytometry. IP-10 and TARC were determined by ELISA.

**Results:** We found that there was no difference among the groups concerning the percentage of T memory cells (A: 27.33 $\pm$ 7.54 vs B: 24.88 $\pm$ 6.23 vs C: 25.65 $\pm$ 6.43 vs D: 27.22 $\pm$ 5.52 %, A vs B vs C vs D, p=NS). However, when the percentage of CXCR3<sup>+</sup> T memory cells was analyzed, we found that in groups A and B it was significantly lower than in groups C and D (A: 40.10 $\pm$ 10.46; B: 42.04 $\pm$ 11.22; C: 53.98 $\pm$ 8.23; D: 53.12 $\pm$ 6.45 %; A vs C, D: p<0.001; B vs C, D: p<0.01), while there was no difference between groups C and D. Simultaneously, the percentage of CCR4<sup>+</sup> T memory cells was also found to be significantly lower in groups A and B than in groups C and D (A: 31.65 $\pm$ 9.69; B: 31.42 $\pm$ 8.23; C: 39.92 $\pm$ 9.24; D: 40.96 $\pm$ 7.29%; A vs C, D and B vs C, D p<0.01) also without difference between groups C and D. On the other hand, IP-10 and TARC levels were significantly higher in groups A and B than in groups C and D (A: 146.99 $\pm$ 68.58; 399.55 $\pm$ 322.56, B: 133.03 $\pm$ 63.19; 383.35 $\pm$ 120.97, C: 118.96 $\pm$ 87.42; 241.72 $\pm$ 164.61, D: 89.28 $\pm$ 19.89; 232.80 $\pm$ 89.34 pg/ml, respectively; A vs C, D and B vs C, D p<0.05), also without differences between groups C and D.

**Conclusion:** Our results demonstrated that the beginning of T1D was associated with the decrease in CXCR3<sup>+</sup> and CCR4<sup>+</sup> subsets of T memory cells, together with the increase in IP-10 and TARC levels, probably reflecting their homing and accumulation into inflamed pancreatic islets. However, these changes could not be identified in the nondiabetic FDRs, thus implying that the onset of T1D might be strongly influenced on the level of these subsets of T memory cells and associated chemokines.

## 476

### Can some differences be found in T regulatory cell count and priming in cord blood of children born to type 1 diabetic mothers?

K. Stechova<sup>1</sup>, T. Ulmannova<sup>1</sup>, D. Bartaskova<sup>2</sup>, J. Norkova<sup>1</sup>, I. Spalova<sup>3</sup>;

<sup>1</sup>Paediatric dpt., <sup>2</sup>Dpt. of Internal Medicine, <sup>3</sup>Dpt. of Gynaecology and Obstetrics, University Hospital Motol and 2nd Medical Faculty of Charles University, Prague, Czech Republic.

**Background and aims:** Type 1 diabetes (T1D) develops due to autoimmune pancreatic beta cells destruction. The effect of diabetes on overall pregnancy

outcome is well documented. However, much less is known about the effect of maternal autoimmune diabetes on the developing foetal immune system. The risk of T1D development in a child of T1D mother who was diagnosed prior pregnancy is lower than e.g. in a child of T1D father. This discrepancy supports the theory that there is some immunoregulatory influence on her baby. For this reason we decided to study T regulatory cells (Tregs) which are important in immunoregulation and for autoimmune diseases pathogenesis. Moreover human Tregs cord blood studies related to T1D are limited and there are only two studies from Scandinavia on this topic which suggested certain differences in Tregs in cord blood of children born to T1D mothers.

**Materials and methods:** Tregs defined as CD4<sup>+</sup>CD25<sup>+</sup>CD127<sup>-</sup> in cord blood (CB) samples were investigated in our study by flow cytometry (FACS) and 20 T1D mothers, 20 gestation diabetes mothers treated by insulin and 45 healthy controls were enrolled. Markers of naive resp. primed cells (CD45RA/RO) were analysed by FACS too. Inclusion criteria were gestational age at least 35+0 weeks, no major maternal or foetal complications (as preeclampsia, asphyxia etc.), maternal HbA1c in all trimesters below 7% according to IFCC (International Federation of Clinical Chemistry and Laboratory Medicine).

**Results:** We found only that CB from babies of T1D mothers contained 6.8 % Tregs/total T helper lymphocytes (Th) in comparison to 9.4 % in healthy controls (p = 0.045). Other differences were not significant and results were not influenced e.g. by delivery mode (Caesarean section vs physiological labour etc.).

**Conclusion:** If an establishment of specific immunological tolerance in foetus of T1D mother really exists, it seems to be rather due to other factors than just to changes in Tregs count (which was moreover found to be decreased in our study). We are currently focused on explanation why children of T1D mothers suffer from diabetes less frequently than other first degree relatives by using functional analysis of Tregs. Insights in to this phenomenon would be useful e.g. for construction of immunointervention therapy.

## 477

### T regulatory cells in the peripheral blood of relatives of type 1 diabetes patients

A.N. Petsiou<sup>1</sup>, S.A. Paschou<sup>1</sup>, A. Karamoutsios<sup>2</sup>, G. Vartholomatos<sup>2</sup>, N. Kolaitis<sup>2</sup>, A. Tsatsoulis<sup>1</sup>, G.K. Papadopoulos<sup>3</sup>;

<sup>1</sup>Department of Endocrinology, Medical School, University of Ioannina,

<sup>2</sup>Unit of Molecular Biology, Laboratory of Haematology, University Hospital of Ioannina, <sup>3</sup>Laboratory of Biochemistry and Biophysics, Epirus Institute of Technology, Arta, Greece.

**Background and aims:** Type 1 diabetes mellitus (T1D) is believed to result from autoimmune destruction of the beta cells of the pancreas, but there is no unifying theory on the disease immunopathogenesis. An approach to immune abnormalities, could be done through the study of first degree relatives (FDR) of affected individuals, because even though T1D appears in “naive” families, FDR of T1D patients are considered a high-risk group for the disease. In order to investigate the mechanisms involved in the dysregulation of immune self tolerance, we studied T regulatory cells (Tregs) in families with an index case of T1D. Tregs are a subpopulation of CD4 T cells which appear to have the ability of contact-dependent suppression and regulation of the immune response. This subpopulation is characterised by high surface expression of the IL-2 receptor alpha chain (CD25) and down-regulation of the IL-7 $\alpha$  (CD127), which is correlated with high expression of the intracellular forkhead/winged-helix family transcription factor p3 (FoxP3), the most specific marker of Tregs. We had previously shown that Tregs are CD4<sup>dim</sup>CD25<sup>high</sup>CD127<sup>low</sup> T cells and are significantly reduced in newly-diagnosed and long-standing type 1 diabetes patients, compared to controls.

**Materials and methods:** Four colour flow cytometry (using the following markers: anti-CD4-PerCP, anti-CD25-APC, anti-CD127-PE, anti FoxP3-Alexa 488) was performed in peripheral blood of 38 FDR (17 siblings, age 22.7  $\pm$  10.4 years (mean  $\pm$  sd), 5 children aged 28.2  $\pm$  2 years, 9 mothers aged 36.4  $\pm$  7.8 years, and 7 fathers aged 46  $\pm$  7.8 years) and 45 healthy controls aged 31.6  $\pm$  14 years. We defined Tregs as the subpopulation of CD4<sup>dim</sup>CD25<sup>high</sup>CD127<sup>low</sup> T cells. In order to verify by independent means the estimated percentage of Tregs, we correlated this estimate with the percent of CD127<sup>low</sup> T cells (a hallmark of Tregs) within the top 7% of CD4<sup>+</sup>CD25<sup>high</sup> T cells (a percent that totally covers the putative Tregs population, active and resting), calling this the verifying population.

**Results:** In 12 controls tested, FoxP3 was expressed in 91.32  $\pm$  4.98 % of so-defined Tregs. The correlation between the percent of Tregs and the percent of CD127<sup>low</sup> T cells in the verifying population was very significant at the

$p < 0.01$  level ( $r = 0.899$ ). The Tregs population was not significantly lower ( $p < 0.05$ ) for any of the subgroups, as seen on the following table.

	TREGS % of CD4 T cells (mean $\pm$ sd)	$p$ (versus control)	VERIFYING POPULATION (mean $\pm$ sd)	$p$ (versus control)
Control	3.31 $\pm$ 0.87		67.78 $\pm$ 8.80	
Siblings	2.77 $\pm$ 1.12	0.087	62.97 $\pm$ 14.94	0.149
Mothers	3.2 $\pm$ 1.16	0.792	64.18 $\pm$ 13.67	0.467
Fathers	3.73 $\pm$ 1.57	0.512	70.73 $\pm$ 13.07	0.582
Children	2.8 $\pm$ 0.71	0.193	65.04 $\pm$ 8.46	0.525

**Conclusion:** By an independent means we have established that our method of estimating the percentage of Tregs is reliable and objective. The absence of significant differences in the percentage of Tregs in the various subpopulations of FDR does not rule out the importance of this subpopulation in T1D pathogenesis. An analysis of the phenotype of the Tregs in FDR is in progress. *Supported by: The Hellenic Endocrine Society by a small grant to AT, GKP and GV*

### Autoantibodies against the glutamate transporter GLT1, a specific beta cell plasma membrane protein, in the serum of type 1 diabetes mellitus subjects

C. Perego<sup>1</sup>, E.S. DI Cairano<sup>1</sup>, E. Fino<sup>1</sup>, C. Bazzini<sup>2</sup>, E. Bazzigaluppi<sup>3</sup>, A. Gastaldelli<sup>4</sup>, F. Bertuzzi<sup>5</sup>, A.M. Davalli<sup>6</sup>, F. Folli<sup>7</sup>;

<sup>1</sup>DISMAB Dept of Biol Science Applied to Biosystems, University of Milano, Italy, <sup>2</sup>Biomolecular Science and Biotechnology, University of Milano, Italy, <sup>3</sup>San Raffaele Hospital, Milano, Italy, <sup>4</sup>Institute of Clinical Physiology, CNR, Pisa, Italy, <sup>5</sup>Niguarda Cà Granda Hospital, Milano, Italy, <sup>6</sup>Internal Medicine, Diabetes & Endocrinology Unit, San Raffaele Hospital, Milano, Italy, <sup>7</sup>Medicine Diabetes Division, University of Texas Health Science Center, San Antonio, USA.

**Background and aims:** Autoantibodies against  $\beta$ -cell membrane proteins could directly mediate cytotoxicity in T1DM. Islet cell surface autoantibodies (ICSA) have been previously described but the nature of these autoantigens remained elusive. We have recently shown that the glial glutamate transporter (GLT1) is selectively expressed on the plasma membrane of human  $\beta$ -cells where it physiologically controls the extracellular glutamate concentration and prevents glutamate-induced  $\beta$ -cell death. We here explored the possibility that GLT1 could be a novel T1DM autoantigen and that putative anti-GLT1 autoantibodies could be pathogenic.

**Materials and methods:** A cell-based (GLT1-transfected cells) immunofluorescence, immunoprecipitation and Elisa assays were used to verify the presence of anti-GLT1 antibodies in serum samples from 43 T1DM patients and 35 healthy controls. We used indirect immunofluorescence, uptake and cell death assays to evaluate the possible immunopathological consequences of Ig binding to surface epitope of living target cells expressing GLT1. Data are expressed as mean value  $\pm$  SD. The study has been reviewed by the local ethics committee

**Results:** Using the cell-based immunofluorescence assay we found antibodies against GLT1 in 20 of 43 (46%) patients with T1DM and in 0 of 35 controls ( $p < 0.0001$ ; one-sided Fisher's exact test). Results were confirmed by ELISA assay performed on GLT1-expressing COS7 cells ( $p < 0.001$ ). T1DM but not control sera, immunoprecipitated a protein extracted from brain lysate, human islets of Langerans and GLT1-transfected COS7 cells of the same molecular weight of GLT1 and recognized by anti-GLT1 antibodies. Cluster and principal component analysis revealed that GLT1-immunoreactivity identified a novel subgroup of T1DM subjects, distinct from those identified by GADA, IA-2A and IAA. Exposure of  $\beta$ TC3 cells to GLT1-positive sera supplemented with active complement disrupted membrane integrity, increased Propidium iodide uptake ( $3.7 \pm 0.7$  fold increase; mean percentage of  $\beta$ -cells damaged by complement was  $17 \pm 5\%$  for GLT1-positive sera and  $3.6 \pm 0.2$  for control sera,  $p < 0.05$ ) and induced cell death. In the absence of complement, 9 out of 20 GLT1-positive T1DM sera (38%) severely downregulated the [<sup>3</sup>H]-D-Aspartic acid uptake in  $\beta$ TC3 cell cultures ( $> 60\%$  inhibition of uptake relative to untreated cells,  $p < 0.01$ ). Downregulation of GLT1 function was associated to protein internalization into endocytic/degradative pathway and led to increased apoptosis ( $4.6 \pm 0.3$  fold increase; mean percentage of TUNEL positive cells was  $15.3 \pm 3.5\%$  for 2 GLT1-positive sera and  $3.2 \pm 0.8$  for control sera).

**Conclusion:** GLT1 is a novel T1DM autoantigen and anti-GLT1 autoantibodies by binding to  $\beta$ -cells may initiate potentially pathogenic mechanisms including complement activation with  $\beta$ -cell membrane damage, as well as GLT1 down-regulation and disruption of glutamate homeostasis.

### Clinical, metabolic and immunologic characteristics in adult patients with type 1 diabetes. Onset and short term prognosis over more than a decade in a Mediterranean area

A.M. de Hollanda<sup>1</sup>, C.M. Quirós<sup>1</sup>, A.J. Amor<sup>1</sup>, G.B. Aranda<sup>1</sup>, M. Vidal<sup>1</sup>, M. Jansà<sup>1</sup>, M. Giménez<sup>1</sup>, R. Casamitjana<sup>2</sup>, I.J. Conget<sup>1</sup>, E. Esmatjes<sup>1</sup>; <sup>1</sup>Diabetes Unit. Endocrinology Department, <sup>2</sup>Hormonology Unit, Hospital Clínic i Universitari, IDIBAPS, Barcelona, Spain.

**Introduction:** Around one third of new cases of type 1 diabetes (T1D) in Catalonia are diagnosed in subjects aged above 18 years. The aim of our study was to characterize a group of non-pediatric subjects with newly diagnosed T1D and to evaluate the short term prognosis of the disease under a specific treatment program and conventional intensive insulin therapy over more than a decade.

**Materials and methods:** We conducted a longitudinal, prospective, unicenter study including all subjects with an age  $\geq 18$  and  $\leq 40$  years recently diagnosed with T1D (1995-2010). Clinical characteristics, metabolic parameters, pancreatic  $\beta$  cell function (basal and glucagon stimulated c-peptide), and the presence of pancreatic autoantibodies (GAD, IA2 and IAA) were evaluated at onset and after 12 months of follow-up. All the subjects received our specific therapeutic education programme for patients with newly-diagnosed T1D.

**Results:** We included 271 patients at diagnosis, 62% women, mean age  $27 \pm 6.6$  years, 95% spanish native, with a duration of symptoms of  $8.9 \pm 9.7$  weeks. The diagnosis of T1D was performed in 28% of subjects in hyperglycemia, 52% in ketosis and 20% in ketoacidosis (KA). The mean BMI was of  $22.1 \pm 3.5$  kg/m<sup>2</sup>, HbA<sub>1c</sub>  $11.2 \pm 2.7\%$ , basal C-peptide  $0.7 \pm 0.4$  ng/mL, stimulated C-peptide  $1.3 \pm 0.7$  ng/mL. With respect pancreatic autoantibodies, GAD were positive in 77%, IA2 in 55% and IAA in 30% of subjects. Nine percent of the patients were negative for all three autoantibodies. KA at onset was associated with greater weight loss, higher HbA<sub>1c</sub> and lower C-peptide levels. After 12-months of follow-up, the BMI was  $23.9 \pm 3.7$  kg/m<sup>2</sup>, with a weight gain of  $4.6 \pm 8.6$  kg. On average, the HbA<sub>1c</sub> was  $6.8 \pm 3.6\%$ , with 67% of patients being  $< 7\%$ .  $\beta$  cell function remained unaltered in comparison with that observed at the onset of the disease ( $0.7 \pm 0.5$  and  $1.2 \pm 0.9$  ng/mL, basal and stimulated C-peptide, respectively). Regarding changes in clinical and metabolic characteristics at diagnosis and during the follow-up over the period of study, the only observed difference was a significant increase in HbA<sub>1c</sub> at onset ( $10.5 \pm 2.5\%$  to  $12.4 \pm 2.9\%$ ) from 1995-2000 to 2006-2010;  $p < 0.001$ ).

**Conclusion:** Our data collected from young adults with newly diagnosed T1D from a Mediterranean area indicates that the clinical presentation, metabolic and immunological characteristics, as well as, short-term prognosis has not substantially varied during more than a decade.

## 480

### Serum GADA detected by AID in type 2 diabetes reversely correlates to islet function

X. Wang<sup>1</sup>, M. Yin<sup>1</sup>, J. Yu<sup>1</sup>, J. Jia<sup>1</sup>, C.S. Hampe<sup>2</sup>;

<sup>1</sup>Department of Endocrinology, Jiangsu Province Hospital of TCM, Nanjing, China, <sup>2</sup>Department of Medicine, Department of Endocrinology, Jiangsu Province Hospital of TCM, Seattle, USA.

**Background and aims:** We hypothesize glutamate decarboxylase autoantibody (GADA) is induced in the background of type 2 diabetes (T2D) when islet  $\beta$  cells are damaged to shedding auto-antigens. The longer diabetic course and more severely impaired islet function will increase GADA titer. GADA in T2D patients is masked by its specific AID and not detected by routine assays. Our previously work demonstrated GADA in T2D patients could be recognized by its specific anti-idiotypic antibody (AID) in ELISA. We designed this study to investigate relationship between GADA and diabetic course and islet function in T2D.

**Materials and methods:** Sera from 26 T2D were tested for GADA by routine luciferase immunoprecipitated assays (LIPS) and ELISA on immobilized human GADA specific AID. Sera immunoglobulins captured by AID covalently linked to protein A sepharose were analyzed by LIPS after elution. Monoclonal

human GADA b96.11 was used as standard or positive controls in all above assays. Relationships between GADA titer detected by ELISA with either diabetic course or fast C-peptide in 13 patients were evaluated by linear regression.

**Results:** GADA in all the samples is negative in routine LIPS but was detected in AID based ELISA. B96.11-like GADA concentration was  $70.32 \pm 13.49$  µg/ml in the 26 samples. Immunoglobulin bound to AID was proved to be GADA in LIPS after elution. Diabetic course is positively linear related with GADA tested by ELISA while fast C-peptide negatively linear correlates with GADA recognized by AID (Fig A and B).

**Conclusion:** Our findings suggest GADA exists in T2D and may be a marker of islet β cell function.

A: diabetic course positively related with GADA in T2D

B: fast C-peptide reversely related with GADA in T2D

**Natural Killer T cell IL-2 cytokine release is inhibited by the monoclonal autoantibody IC2 and might be restored by its anti-idiotypic antibodies**

K.L. Jensen<sup>1</sup>, I.D. Pedersen<sup>1</sup>, L. Åkesson<sup>2</sup>, Å. Lernmark<sup>2</sup>, I. Klöting<sup>3</sup>, F. Niessner<sup>3</sup>, J. Svalgaard<sup>1</sup>, K. Engkilde<sup>1</sup>, K. Buschard<sup>1</sup>, C.H. Brogren<sup>1</sup>;

<sup>1</sup>The Bartholin Institute, Rigshospitalet, Copenhagen, Denmark, <sup>2</sup>University Hospital Malmö, Sweden, <sup>3</sup>University Greifswald, Karlsburg, Germany.

**Background and aims:** Identifying factors, which can prevent beta cell death is a major objective in diabetes research. The beta cell destruction in type 1 diabetes (T1D) is mediated by autoimmune T-cells under regulatory control of Natural Killer T cells (NKT cells) receiving stimulatory signals from certain CD1d-lipid complexes. It is thought that an inhibition of the stimulatory effects of NKT cells might be the reason for the degradation of beta cells in T1D. The aim of this study was to confirm the inhibitory role of the beta-cell surface specific monoclonal autoantibody IC2 on the regulatory NKT cells. This would mean that anti-idiotypic antibodies binding the paratope of IC2 could block the inhibitory effect of IC2 and thereby maintain the normal effect of NKT cells.

**Materials and methods:** We used a modified functional NKT-hybridoma assay with CD1d lipid complexes. One microgram of soluble mouse CD1d was coated on a flat-bottom 96-well plate for 18 hrs in 4 degrees in PBS. After washing 4 µg/ml IC2 + alfa-galactosyl-ceramide was mixed and added to the CD1d-coated plate and left for incubation at 37 degrees celsius for 4 hrs before addition of NKT 1.2 cells. For the NKT 19.3 cells 250µg/ml IC2 + lysosulfatide was mixed and added to the CD1d coated plate and left for incubation at 37 degrees celsius for 4 hrs before addition of NKT 19.3 cells. For both cell types, supernatants were collected after 17 hrs to measure IL-2 secretion by sandwich-ELISA.

**Results:** We show for the first time that IC2 can inhibit the IL-2 secretion from NKT type I and probably also from NKT type II cells. We found, the

inhibition most pronounced when IC2 was preincubated with alfa-galactosyl-ceramide before it was added to the CD1d coated plate, and the NKT cells then added subsequently. We saw that the addition of IC2 inhibited the IL-2 cytokine release of NKT type I cells with 56.8 %, when 4 µg/ml IC2 was added and NKT type II cells with 24.3 % when 250 µg/ml IC2 was added. When adding 4 µg/ml of rat IgM control, there was practically no inhibition, as expected (Figure).

**Conclusion:** According to our preliminary findings, the CD1d stimulation of type I NKT cells and to some degree also type II NKT cells can be inhibited by IC2. This makes the antibody interesting for future development of drugs preventing the development of autoimmune T-cell mediated diseases caused by a disturbance of the regulatory NKT cell signal. Furthermore, this suggests that the IC2 corresponding anti-idiotypic antibodies could have a preventive effect on T1D by blocking the IC2 inhibition of the NKT stimulation and thereby restoring the normal NKT cell activity.

### Ca<sub>v</sub>1.3 L-type channel mediated Ca<sup>2+</sup> flux regulates human insulin release and feeds back to own mRNA expression

T.M. Reinbothe<sup>1</sup>, S. Alkayyal<sup>2</sup>, E. Ahlqvist<sup>2</sup>, T. Tuomi<sup>3</sup>, B. Isomaa<sup>4</sup>, V. Lyssenko<sup>2</sup>, E. Renström<sup>1</sup>;

<sup>1</sup>Islet Pathophysiology, Lund University Diabetes Centre, Malmö, Sweden,

<sup>2</sup>Diabetes and Endocrinology, Lund University Diabetes Centre, Malmö,

Sweden, <sup>3</sup>Helsinki University Central Hospital, Finland, <sup>4</sup>Biomedicum Helsinki, Folkhälsan Research Center, Finland.

**Background and aims:** L-type calcium channels are essential for pancreatic beta-cell function and they have been well studied in rodents. Here, we set out to determine which L-type channel isoform is operative in human pancreatic beta-cells and how it may be regulated in physiology and disease.

**Material and methods:** Ca<sub>v</sub>1.3 expression was compared in rat islets, INS1 832/13 cells and human islets using quantitative PCR and microarrays respectively and we assessed Ca<sub>v</sub>1.3 dependent insulin release in human islets. Human beta-cells were enriched using FACS and NewPortGreen. Phenotype/genotype associations of three single nucleotide polymorphisms (SNPs) were investigated in 8987 non-diabetic and 3298 type 2 diabetic subjects from Finland and Sweden. We used RNAi techniques to study the effect of Ca<sub>v</sub>1.3 knockdown on insulin release in INS1 832/13 cells and on exocytosis in human beta-cells.

**Results:** We find Ca<sub>v</sub>1.3 expression being the major L-type isoform in rat islets, the INS1 832/13 cells line, human islets and in FACS enriched human beta-cells on mRNA level (1130±23 Ca<sub>v</sub>1.3 transcripts vs. 19±1 Ca<sub>v</sub>1.2 transcripts). Protein is also mainly localizing to beta-cells within human islets. Ca<sub>v</sub>1.3 mRNA is less abundant in islets from diabetic subjects compared to controls (754±93 in cases vs. 1235±64 Ca<sub>v</sub>1.3 transcripts in controls; p=0.01) and this reduction in expression coincides with decreased human islet insulin release *in vitro*. Ca<sub>v</sub>1.3 knockdown reduced glucose stimulated insulin secretion in INS1 832/13 cells (3.8±0.4 ng/mg protein×h in siCa<sub>v</sub>1.3 treated vs. 6.7±0.7 ng/mg protein×h in control cells; p=0.0026) and exocytosis in human beta-cells (41±4 fF in siCa<sub>v</sub>1.3 treated vs. 68±8 fF in control cells; p=0.009) respectively. Genotype/phenotype association analyses revealed that the C allele of the CACNA1D gene SNP rs312480 was associated with reduced mRNA expression of the channel *in vitro* (CC: 1.4±0.1 vs. CT: 2.2±0.3 ng/islet×h p=0.04; T/T n.a.) and decreased insulin secretion *in vivo* (IVGTT, β=-0.085; p=0.027), whereas rs312486/G and rs9841978/G both associated with type 2 diabetes (OR=1.16 and 1.17; p=0.00115 and 6.4×10<sup>-5</sup>). Furthermore, we find high glucose *in vitro* to L-type channel dependently stimulate Ca<sub>v</sub>1.3 expression in human islets 1.7-fold (+/- 0.2) with the L-type channel blocker isradipine completely abolishing this effect (0.9-fold +/- 0.1). This raised Ca<sub>v</sub>1.3 expression contributes to increased intracellular calcium levels (2.12±0.04 AUC<sub>i</sub> for islets cultured for 24h at 20mM vs. 1.66±0.04 when cultured at 5 mM glucose; p=7×10<sup>-4</sup>).

**Conclusion:** The L-type Ca<sup>2+</sup> channel Ca<sub>v</sub>1.3 is important for appropriate glucose induced insulin secretion and deregulated expression as well as common variants in CACNA1D might contribute to type 2 diabetes.

### Apolipoprotein CIII hyperactivates beta cell Ca<sub>v</sub>1 channels by coactivating PKA and Src kinase

Y. Shi<sup>1</sup>, G. Yang<sup>1</sup>, J. Yu<sup>1</sup>, L. Yu<sup>1</sup>, R. Westenbroek<sup>2</sup>, W.A. Catterall<sup>2</sup>, L. Juntti-Berggren<sup>1</sup>, P.-O. Berggren<sup>1</sup>, S.-N. Yang<sup>1</sup>;

<sup>1</sup>Department of Molecular Medicine and Surgery, Karolinska Institutet,

Stockholm, Sweden, <sup>2</sup>Department of Pharmacology, University of Washington, Seattle, USA.

**Background and aims:** Apolipoprotein CIII (ApoCIII) not only serves as an inhibitor of triglyceride hydrolysis, but also participates in diabetes-related pathological events. It has been demonstrated that elevated ApoCIII acts as a diabetogenic serum factor to drive β cell destruction via hyperactivation of voltage-gated Ca<sup>2+</sup> (Ca<sub>v</sub>) channels in the pancreatic β cell. ApoCIII can also bind to distinct cell surface receptors including scavenger receptor class B type I, Toll-like receptor 2 and uncharacterized binding sites relaying corresponding signals to their downstream effectors, e.g., β1 integrin, pertussis

toxin-sensitive G proteins, NF-κB and protein kinases. However, the molecular mechanisms whereby ApoCIII hyperactivates β cell Ca<sub>v</sub> channels are not known. This study aimed at mechanistically dissecting ApoCIII-induced hyperactivation of β cell Ca<sub>v</sub> channels at molecular level.

**Materials and methods:** Mouse islet β cells/insulin-secreting RINm5F cells and patch-clamp techniques/pharmacological manipulation/immunoblot analysis were employed.

**Results:** ApoCIII incubation significantly increased channel number, elevated open probability, prolonged mean open time and shortened mean closed time of single Ca<sub>v</sub>1 channels as compared with incubation with vehicle solution. Whole-cell Ca<sup>2+</sup> current densities in the ApoCIII group were significantly higher than those in the control group. In striking contrast, whole-cell Ca<sup>2+</sup> currents were similar between control cells and cells incubated with ApoCIII in the presence of the Ca<sub>v</sub>1 channel blocker nimodipine. The effect of ApoCIII was not significantly influenced by PKC inhibition. However, it was marginally reduced by individual inhibition of PKA or Src kinase. Importantly, either combined inhibition of PKA, PKC and Src kinase or coinhibition of PKA and Src kinase significantly counteracted the effect of ApoCIII on β cell Ca<sub>v</sub> channels. In addition, ApoCIII treatment did not alter β cell Ca<sub>v</sub>1 channel expression at the protein level.

**Conclusion:** ApoCIII selectively hyperactivates β cell Ca<sub>v</sub>1 channels through coactivation of PKA and Src kinase. ApoCIII-induced hyperactivation of β cell Ca<sub>v</sub>1 channels is characterized by enriched density and increased activity of functional Ca<sub>v</sub>1 channels in the β cell plasma membrane. This novel signal-transduction pathway may serve as an innovative drug target for the prevention of Ca<sup>2+</sup>-dependent β cell death in association with diabetes.

### Multi-electrode arrays reveal glucose-dependent action potentials and slow waves that differ by their calcium sensitivity in mouse islet cells

F. Lebreton<sup>1</sup>, A. Caro<sup>1</sup>, A. Quotb<sup>2</sup>, J. Gaitan<sup>1</sup>, J. Laloum<sup>1</sup>, Y. Bornat<sup>2</sup>,

S. Renaud<sup>2</sup>, J. Lang<sup>1</sup>, M. Raoux<sup>1</sup>;

<sup>1</sup>Université Bordeaux 1, UMR CNRS 5248 - CBMN, Pessac, <sup>2</sup>UMR CNRS

5218, Université Bordeaux 1, IPB, Talence, France.

**Background and aims:** The β-cells of the islets of Langerhans generate electrical signals upon stimulation by glucose or other nutrients which are modulated by hormones. The ensuing increase in [Ca<sup>2+</sup>]<sub>i</sub> regulates important aspects such as exocytosis of secretory granules and gene expression. To overcome some limits of intracellular recordings, we have recently developed and published a novel electrophysiological approach based on the extracellular recording of action potentials (AP) with multi-electrode arrays (MEAs). This allowed for the first time long-term, non-invasive and multicellular recordings on islets. In the present work using this device, we report the existence, in addition to action potentials, of slower electrical signals of larger amplitude in islets.

**Materials and methods:** Clonal INS 832/13 β-cells and partially dissociated mouse islets were cultured for 2-4 days on MEAs containing 60 extracellular microelectrodes (Multichannel Systems, MCS). Electrical signals were recorded with a MEA1060-Inv-BC-Standard amplifier (MCS), with a band-pass of 0.1-3000 Hz, and were analysed off-line with MC\_Rack software (MCS).

**Results:** Electrophysiological studies in islets are generally conducted in the presence of high levels of extracellular Ca<sup>2+</sup> (~2.5 mM). Under these conditions, islet cells recorded on MEAs generated characteristic glucose-induced APs (40-60 ms duration, 10-50 μV). Decreasing Ca<sup>2+</sup> to more physiological conditions such as 1.2 mM or even to 0.4 mM, we observed the existence of glucose-induced slow electrical waves (SWs) (duration 800-1500 ms) with large amplitudes (30-200 μV). APs were present in 1.2 mM of external Ca<sup>2+</sup>, and with smaller amplitude in 0.4 mM Ca<sup>2+</sup>. Note that they were observed only during the presence of SWs. Like the APs, the SWs were absent at 3 mM of glucose, evoked in a reversible manner by 11 and 15 mM of glucose, and inhibited by both the L-type Ca<sup>2+</sup>-channel blocker nifedipine (25 μM) and adrenalin (5 μM). The SWs persisted during the application of 15 mM of glucose for up to 2 h with a mean frequency of 0.55±0.03 (n=24). Long-term recordings also revealed very regular oscillations in the SWs frequency with alternations of short silent phases and longer active phases. Interestingly, the same experiments performed with 0.4 to 5 mM of external Ca<sup>2+</sup> showed that the clonal INS 832/13 β-cells generate glucose-induced APs but not SWs. To gain insight into the nature of the SWs we started to investigate the putative involvement of multicellular processes in primary cells. Our preliminary results indicate that the gap junction inhibitor heptanol-1 (3.5 mM) abolished the SWs.

**Conclusion:** Our current observations extend our previous reports on the versatility of MEAs in islet research by the demonstration of two types of electrical signals evoked by glucose. Their difference in sensitivity to calcium suggests differences in their generation.

### Role of anoctamin 1 (TMEM16A) as a volume regulated anion channel in insulin-producing cells

W.J. Malaisse<sup>1</sup>, M. Virreira<sup>2</sup>, Y. Zhang<sup>1</sup>, R. Crutzen<sup>2</sup>, N. Bulur<sup>1</sup>, P. Lybaert<sup>1</sup>, P.E. Golstein<sup>2</sup>, A. Sener<sup>1</sup>, R. Beauwens<sup>2</sup>;

<sup>1</sup>Laboratory of Experimental Hormonology, <sup>2</sup>Laboratory of Cell and Molecular Physiology, Université Libre de Bruxelles, Belgium.

**Background and aims:** Stimulation of insulin release by D-glucose entails two major ionic events, i.e. the closing of ATP-sensitive potassium channels prevailing at concentrations of the hexose in the range up to the threshold value for its insulinotropic action and the gating of volume regulated anion channels occurring mainly at higher concentrations of D-glucose. The present study aimed at investigating the possible role of anoctamin 1 (Ano1 or TMEM16A), a member of the TMEM16 or anoctamin family, as a volume regulated chloride channel in insulin-producing cells.

**Materials and methods:** RNA was isolated from rat and human islets, as well as BRIN-BD11 cells, for the study by RT-PCR of anoctamin 1, anoctamin 6 (Ano6 or TMEM16F) and anoctamin 10 (Ano 10 or TMEM16K) gene expression. Immunohistochemistry of pancreatic sections was performed using a standard ABC-DAB technique. For the measurement of insulin secretion, groups of 8 rat islets each prepared by the collagenase method were incubated for 90 min in a salt-balanced medium containing bovine serum albumin. Voltage measurements in BRIN-BD11 cells were performed in nystatin-perforated whole cell configuration patch clamp experiments.

**Results:** Ano1 mRNA was found in rat and human islets, with a lower level in BRIN-BD11. In rat islets Ano1 and Ano6 were predominant, with a lower level of Ano10. Immunohistochemistry confirmed the presence of Ano1 in mouse, rat and human pancreatic islets. In rat isolated pancreatic islets incubated in the presence of 16.7 mM D-glucose, tannic acid (TA), inhibitor of Ano1, caused a concentration-related decrease ( $p < 0.01$ ) of insulin output ( $\mu\text{U}/\text{islet}$ ;  $n=22-24$ ) from a control value of  $303 \pm 16$  to  $245 \pm 13$  (10  $\mu\text{M}$  TA),  $227 \pm 14$  (30  $\mu\text{M}$  TA),  $175 \pm 11$  (50  $\mu\text{M}$  TA) and  $154 \pm 14$  (100  $\mu\text{M}$  TA), as compared to a basal value recorded in the sole presence of 2.8 mM D-glucose of  $43 \pm 4$ . Tannic acid (100  $\mu\text{M}$ ) also opposed the spiking activity and depolarization of the plasma membrane evoked by exogenous  $\text{H}_2\text{O}_2$  (100  $\mu\text{M}$ ) in BRIN-BD11 cells exposed to 5.0 mM D-glucose, the latter observation being consistent with the role recently attributed to NAD(P)H oxidase-derived  $\text{H}_2\text{O}_2$  as an activator of volume regulated anion channels in insulin-producing cells.

**Conclusion:** The present findings support the view that anoctamin 1 (TMEM16A) indeed acts as a volume regulated channel in insulin-producing cells.

## 486

### Influence of miR-375 on electrophysiological properties of voltage-dependent $\text{Na}^+$ channels in mouse beta cells and INS1-832/13 cells

V.A. Salunkhe<sup>1</sup>, M. Braun<sup>2</sup>, J.L.S. Esguerra<sup>1</sup>, I. Mollet<sup>1</sup>, A. Wendt<sup>1</sup>, M. Stoffel<sup>3</sup>, P. Rorsman<sup>4</sup>, L. Eliasson<sup>1</sup>;

<sup>1</sup>Lund University Diabetes Centre, Clinical Research Centre Malmö, Lund University, Malmö, Sweden, <sup>2</sup>Alberta Diabetes Institute, University of Alberta, Edmonton, Canada, <sup>3</sup>Institute of Molecular Systems Biology, Swiss Federal Institute of Technology, ETH Zurich, Switzerland, <sup>4</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, UK.

**Background and aims:** Glucagon secretion from alpha-cells is dependent on voltage-dependent  $\text{Na}^+$  ( $\text{Na}_v$ ) channels. Both pancreatic alpha- and beta-cells are equipped with these channels which are known to exhibit cell-type specific inactivation properties. MicroRNAs control protein expression and the islet-abundant miR-375 has target genes known to be involved in insulin secretion. We aim to investigate possible targets of miR-375 among  $\text{Na}_v$  channel subunits (gene names  $\text{SCN}$ x) and its subsequent effect on  $\text{Na}_v$  currents properties in beta-cells.

**Materials and methods:** Whole-cell configuration patch-clamp technique was used to investigate the inactivation properties of the  $\text{Na}_v$ -current in a) beta-cells from control and miR-375 knockout mice (375KO) and b) INS1-

832/13 cells (rat beta-cell line) transfected with FITC- labelled locked nucleic acid (LNA) against miR-375 (anti-miR-375) or scramble LNA oligonucleotide (control). Glucose stimulated insulin secretion assay and RT-qPCR was also performed using INS1-832/13 cells to investigate expression levels of  $\text{Na}_v$  channel subunits during glucose stimulation. TargetScan was used to predict miR-375- $\text{SCN}$ x interactions.

**Results:** The half-maximal inactivation ( $V_h$ ) of  $\text{Na}_v$ -current was  $-83 \pm 1$  mV ( $n=24$ ) in control mice beta-cells. This was shifted to more positive membrane potential in the 375KO ( $V_h = -69 \pm 2$  mV;  $n=30$ ;  $p < 0.001$ ). Thus, in the absence of miR-375 mice beta-cells  $\text{Na}_v$  channel properties becomes more alpha-cell like. In INS1-832/13 cells, the  $V_h$  of  $\text{Na}_v$ -current was  $-57 \pm 2$  mV ( $n=12$ ) in control cells. This was shifted to more negative membrane potential upon treatment with anti-miR-375 ( $V_h = -62 \pm 1$  mV;  $n=25$ ;  $p < 0.01$ ). The  $\text{Na}_v$  current is consistent with the flow of  $\text{Na}^+$  through different  $\text{Na}$ -channel subtypes and miR-375 might target one of these subtypes specifically present in beta-cells. Indeed, computational predictions identified a number of  $\text{Na}_v$  channel subunits as putative targets in species-specific manner, e.g.  $\text{SCN3A}$  in rat and human while  $\text{SCN3B}$  in mouse. Upon glucose stimulation of INS-1 832/13 cells, we observed inverse correlation of miR-375 and  $\text{SCN3A}$  expression levels suggesting possible regulatory interactions.

**Conclusion:** We found direct influence of miR-375 on the electrophysiological properties of  $\text{Na}_v$  channel in mouse beta-cells and INS-1 832/13 cells. The observed shift in half-maximal inactivation of  $\text{Na}_v$ -current in opposite directions was possibly due to species-specific regulation of putative  $\text{Na}_v$  channel subunit targets of miR-375. We conclude that miR-375 apart from being important in exocytosis also has potential roles in the modulation of beta-cell ion channels.

<sup>3</sup>Institut für Pharmakologie und Toxikologie, München, Germany.

**Background and aims:** Insulin-secreting  $\beta$ - and glucagon-producing  $\alpha$ -cells are equipped with voltage-gated  $\text{Na}^+$ -channels ( $\text{Na}_v$  channels).  $\text{Na}_v$  channels are involved in the hormone secretion from pancreatic islet endocrine cells due to its role in the generation of action potentials. This study is to dissect different  $\text{Na}_v$  channel  $\alpha$ -subunits (pore forming subunits) expressed in  $\alpha$ - and  $\beta$ -cells and to understand their involvement in glucagon and insulin secretion.

**Material and methods:** The functional role of the different  $\text{Na}^+$ -channel  $\alpha$ -subunits was analyzed by electrophysiological recordings (patch-clamping) and hormone release measurements in wildtype,  $\text{Scn3a}/\text{Na}_v 1.3$  and  $\text{Scn9a}/\text{Na}_v 1.7$  knockout mice. Molecular identity of  $\text{Na}_v$  channel  $\alpha$ -subunits was confirmed by using single cell RT-PCR and quantitative RT-PCR in mouse and human islets, respectively.

**Results:** Both  $\alpha$ - and  $\beta$ -cells are in possession of rapid inactivating  $\text{Na}^+$  currents. The steady state of inactivation of  $\text{Na}^+$  currents exhibits a biphasic pattern in all  $\alpha$ -cells and 30% of  $\beta$ -cells. In all  $\alpha$ -cells ~70% of  $\text{Na}^+$  currents inactivate at positive potential ( $V_{0.5} = -47$  mV). In  $\beta$ -cells with biphasic inactivation, 50%  $\text{Na}^+$  currents was found to have similar inactivation at -50mV. 70% of  $\beta$ -cells tested exhibited a monophasic inactivation with the  $V_{0.5}$  of -97mV. Application of a broad spectrum  $\text{Na}_v$  channel blocker, tetrodotoxin (TTX), inhibited glucagon secretion when islets were sensing low glucose. The same blocker had no effect on glucose stimulated insulin secretion. At the molecular level, human and mouse pancreatic islets express similar  $\text{Na}^+$ -channel subunit complements (principally  $\text{SCN3A}/\text{Scn3a}$ ,  $\text{SCN8A}/\text{Scn8a}$ ,  $\text{SCN9A}/\text{Scn9a}$ ,  $\text{SCN1B}/\text{Scn1b}$  and  $\text{SCN3B}/\text{Scn3b}$ ). Ablation of  $\text{Scn3a}/\text{Na}_v 1.3$  resulted in the suppression of the  $\text{Na}^+$ -current active at physiological voltages in both  $\alpha$ - and  $\beta$ -cells and inhibited glucagon and insulin secretion triggered by low and high glucose, respectively. Cell-specific ablation of  $\text{Scn9a}^{-/-}/\text{Na}_v 1.7$  in  $\alpha$ - or  $\beta$ -cells did not affect glucagon or insulin secretion but led to the selective removal of a  $\text{Na}^+$ -current component inactivating at membrane potentials more negative than -70 mV in  $\beta$ -cells whereas only small effects were seen in  $\alpha$ -cells. These data suggest that Nav1.3 represents the functionally important  $\text{Na}^+$ -channel  $\alpha$ -subunit in  $\alpha$ - and  $\beta$ -cells.

**Activation of nonselective cation channels via cAMP-EPAC2 pathway is involved in exendin-4 potentiated insulin secretion**M. Yoshida<sup>1</sup>, S. Yamato<sup>1</sup>, K. Dezaki<sup>2</sup>, M. Nakata<sup>3</sup>, M. Kawakami<sup>1</sup>, T. Yada<sup>3</sup>, M. Kakei<sup>1</sup><sup>1</sup>Internal Medicine <sup>2</sup>Physiology <sup>3</sup>Integrated Physiology, Jichi Medical University, Shimotsuke, Japan.

**Background and aims:** Glucagon-like peptide 1 (GLP-1) stimulates glucose-dependently insulin secretion that is brought about by increase in the intracellular  $\text{Ca}^{2+}$  concentration in a dose-dependent manner at supra-threshold concentration of glucose. There are several lines of evidence that GLP-1 influences ion channels as a mechanism of enhancement of insulin secretion, but all of these are not confirmatory yet. Here we report a novel mechanism of GLP-1 on background non-selective cation channel current (NSCC) in rat pancreatic beta cells.

**Materials and methods:** Perforated whole-cell patch-clamp technique was used in rat pancreatic beta cell. Insulin secretion from isolated islets was measured using ELISA-kit in static incubation.

**Results:** Insulin secretion in the presence of 11.2 mM glucose was increased by  $10^{-9}$  M exendin-4 from  $21.2 \pm 1.48$  ng/10 islets to  $30.9 \pm 1.85$  ng/10 islets (mean  $\pm$  sem,  $P=0.0011$ , unpaired test). The resting membrane conductance that was measured by ramp clamp from -100 mV to -50 mV at 2.8 mM glucose was  $686 \pm 320$  pS/pF ( $n=5$ ), of which the majority of currents were due to ATP-sensitive  $\text{K}^{+}$  channels and this was decreased to  $31.5 \pm 7.6$  pS/pF ( $n=7$ ) by changing to 5.6 mM glucose with 100  $\mu\text{M}$  tolbutamide ( $P<0.05$ , unpaired test). The resting conductance was further increased to  $62.2 \pm 15.7$  pS/pF ( $n=7$ ,  $P<0.05$  with paired test) after addition of  $10^{-10}$  M exendin-4 that is a GLP-1 receptor agonist. Exendin-4 greater than  $10^{-11}$  M elicited inward current at the holding potential of -70 mV and exendin-4 sensitive current reversed around 0 mV, indicating that exendin-4 activated NSCC. The increase in NSCC by exendin-4 was dose-dependent at the concentrations between  $10^{-11}$  M and  $10^{-9}$  M and conversely decreased these increasing effects on NSCC at concentrations greater than  $10^{-9}$  M. The NSCC sensitive to exendin-4 was inhibited by 10  $\mu\text{M}$  ruthenium red, nonspecific blocker of transient receptor potential channels. In the presence of  $10^{-7}$  M exendin-9-39, GLP-1 receptor antagonist, exendin-4 at  $10^{-10}$  M was without effect on NSCC. This indicates involvement of GLP-1 receptor binding followed by activation of NSCC. Dibutyl-*c*-AMP at 1 mM activated the NSCC. In the presence of 10  $\mu\text{M}$  H89, protein-kinase A inhibitor,  $10^{-10}$  M exendin-4 increased NSCC. 8-pCPT-2-*O*-Me-*c*-AMP at 10  $\mu\text{M}$ , EPAC2 activator, also increased the NSCC by an extent similar to that on exposure to exendin-4. We observed that liraglutide, GLP-1 analogue, increased the inward current at -70 mV at  $10^{-10}$  M.

**Conclusion:** Activation of NSCC, presumably a class of transient receptor channel, via cAMP-EPAC2 pathway is involved in GLP-1-mediated beta cell stimulation.

## 489

**Pharmacology of GABAA channels in human pancreatic islets**

Y. Jin, S. Korol, Z. Jin, B. Birnir; Uppsala University, Sweden.

**Background and aims:** Gamma-aminobutyric acid (GABA) is known as the inhibitory neurotransmitter in the adult mammalian central nervous system (CNS). It has also been shown to be secreted from the islets of Langerhans in pancreas where it serves as an important paracrine and autocrine signaling molecule regulating the pancreatic cells excitability through GABAA channels. The GABAA channel is a ligand-gated ion channel permeable to chloride and bicarbonate. When the GABAA channels are activated, they depolarize the  $\beta$ -cell and hyperpolarize the  $\alpha$  and  $\delta$ -cell in the human islets, due to different intracellular chloride concentrations. In pancreatic islets, GABA is synthesized in the  $\beta$ -cells, and released by both vesicular and nonvesicular processes. We have recently shown GABA effectively modulates hormone release in islets from type 2 diabetic and normoglycaemic individuals. Moreover, both phasic and tonic GABAA channels activation were recorded in intact islets. However, the interstitial GABA concentration is not known, and information regarding the islets GABAA channel pharmacology is not available.

**Materials and methods:** We, therefore, applied whole-cell patch-clamp recordings on intact human islets to further investigate the pharmacological characteristics of the native GABAA channels expressed in the islets.

**Results:** The results show that the GABAA channels opening in human pancreatic islets are enhanced relative to the baseline activity when 100 nM GABA is applied but the channels do desensitize in 1  $\mu\text{M}$  GABA. We further examined several known GABAA channel modulators: pentobarbital, diazepam, zolpidem and propofol. The results demonstrated that pentobarbital, diazepam and propofol consistently potentiated the GABAA channels, whereas zolpidem did not, which differs from the pharmacology in CNS.

**Conclusion:** These results support the notion that GABAA channels with very high affinity are present in the islets. Furthermore, the endogenous intra-islet GABA concentration is lower than 100 nM in islets when 20 mM glucose is present. Considering our gene expression data, interestingly, in human islets the  $\pi$  subunit has a high expression level whereas in CNS it is very low. From human genome analysis, the  $\pi$  subunit has a high similarity to the  $\delta$  subunit, a classical extrasynaptic subunit. The incorporation of the  $\pi$  may possibly be the reason for different pharmacological pattern observed in the islets as compared to the CNS, which might potentially be valuable to serve as a novel drug target

**Insulin secretion induced by potassium depolarisation - just a matter of Nernst equilibrium?**

M. Willenborg, M. Belz, K. Schumacher, I. Rustenbeck;

Institute of Pharmacology, Toxicology and Clinical Pharmacy, Technical University of Braunschweig, Germany.

**Background and aims:** The elevation of the external potassium concentration is a widely used maneuver to elicit insulin secretion without affecting energy metabolism or  $\text{K}_{\text{ATP}}$  channel function. The resulting depolarization is thought to be the inevitable consequence of the shift of the Nernst equilibrium. Recently we observed that 15 mM KCl was ineffective to induce insulin secretion despite clearly depolarizing the plasma membrane and increasing  $[\text{Ca}^{2+}]_i$ . By contrast 40 mM, which is commonly used in the field, had a drastic insulinotropic effect accompanied by a stronger depolarization and further elevation of the  $[\text{Ca}^{2+}]_i$ . So the question arose if these different insulinotropic effects of low and high external potassium are just of quantitative or rather qualitative nature.

**Materials and methods:** Membrane potentials and currents of separated NMRI mouse  $\beta$ -cells were measured in the perforated patch mode of patch-clamp technique, cytosolic  $\text{Ca}^{2+}$  concentration ( $[\text{Ca}^{2+}]_i$ ) of NMRI mouse islets was measured by the Fura method. Insulin secretion was measured by batch perfusion of pancreatic islets. All parameters except electrophysiological experiments were performed at 37°C. Patch-clamp experiments were done at room temperature.

**Results:** In presence of a basal glucose concentration 15 mM KCl depolarized pancreatic beta cells by 20.7 mV and led to an increase of  $[\text{Ca}^{2+}]_i$  which was not inferior to an increase induced by 20 mM glucose. However these changes did not result in an increase of insulin secretion. By contrast 40 mM KCl induced a 6-fold increase of secretion. Under these conditions beta cells were depolarized by 41.2 mV accompanied by a stronger increase of  $[\text{Ca}^{2+}]_i$  than performed by 15 mM KCl. To rule out a subthreshold increase of  $[\text{Ca}^{2+}]_i$  by 15 mM KCl, 10  $\mu\text{M}$  cyclopiazonic acid was applied prior to KCl application resulting in an increase of  $[\text{Ca}^{2+}]_i$  comparable to the plateau performed by 40 mM KCl but without stimulatory effect on secretion. Next the effect of the selective L-type calcium channel blocker Nifedipine and the nonselective blocker  $\text{Co}^{2+}$  on membrane potential, -current and  $[\text{Ca}^{2+}]_i$  was tested. 10  $\mu\text{M}$  Nifedipine reduced the KCl induced depolarization by 1.2 mV in case of 15 mM  $\text{K}^{+}$  and by 1.5 mV in case of 40 mM  $\text{K}^{+}$ . 2.5 mM  $\text{Co}^{2+}$  caused a repolarization of 2.9 and 6.1 mV respectively, indicating that high KCl might increase  $[\text{Ca}^{2+}]_i$  not only via activated L-type VDCC. In concordance the effect of Nifedipine on  $[\text{Ca}^{2+}]_i$  was more marked at low  $\text{K}^{+}$  than at high  $\text{K}^{+}$  induced depolarization. Finally the membrane potential was clamped at -30 mV, which is typically reached by 40 mM  $\text{K}^{+}$ . In presence of Tolbutamide and TEA spontaneous electrical activity in form of inward action currents with peak values of 30 pA was observed, which could be abolished by Nifedipine. Subsequent application of 40 mM  $\text{K}^{+}$  transformed this inward spiking into a continuous inward current of  $\approx 20$  pA which was marginally sensitive to Nifedipine application but could be clearly inhibited by  $\text{Co}^{2+}$ .

**Conclusions:** In the present study we could show that the seemingly simple tool potassium induces insulin secretion not only by shifting the Nernst equilibrium but also modulating membrane conductance. It transforms regular inward action currents into continuous Nifedipine insensitive ion fluxes. This might be the reason why strong potassium induced depolarizations do not show action potential spiking while drastically increasing  $[\text{Ca}^{2+}]_i$ .

### Activation of the cholinergic anti-inflammatory pathway to protect pancreatic beta cells against cytotoxic attacks

P. Klee, E. Somme, A. Guerardel, V.M. Schwitzgebel;

Department of Pediatrics, University Hospital of Geneva, Switzerland.

**Background and aims:** Type 1 diabetes (T1DM) results from an auto-immune destruction of more than 90% pancreatic  $\beta$ -cells, leaving few survivors that are insufficient to properly regulate blood glucose. We consider the possibility that the activation of nicotinic acetylcholine (nACh) receptors may protect  $\beta$ -cells from auto-immunity. nACh receptors are channels formed by 5 subunits that form a pathway for ions across the cell membrane. They have been implicated in the control of inflammation, through activation of their  $\alpha 7$  subunit and allow the central nervous system, by activation of efferent nerve fibers, to modulate peripheral inflammation - a mechanism termed "cholinergic anti-inflammatory pathway". nACh receptors are expressed in pancreatic  $\beta$ -cells, but no study has analyzed the effect of their activation on the resistance of  $\beta$ -cells against toxins relevant in the pathogenesis of T1DM. The aim of this work was to test whether the activation of nACh receptors could be implicated in the protection of  $\beta$ -cells exposed to toxins mimicking the environment of a  $\beta$ -cell at the onset of T1DM.

**Materials and methods:** Islets isolated from wild type (WT) mice, as well as from mice knocked out for the  $\alpha 7$  or  $\beta 2$  subunit of nACh receptors were cultured in RPMI medium with or without nicotine or Choline. After 24h, they were exposed during another 24h to a cocktail of IL-1 $\beta$  + TNF $\alpha$  + IFN $\gamma$ , a cocktail of cytokines often used to mimic the surrounding of a  $\beta$ -cell at the onset of T1DM. Cell death was then measured by TUNEL analysis of islet sections. Nitrites, a stable degradation product of nitric oxide (NO) were measured in the culture medium by a Griess reaction.

**Results:** The exposure of WT islets to the above-mentioned cocktail of cytokines showed increased cell death, as compared to untreated islets. Pre-culture with nicotine during 24h significantly decreased the effect of cytokines. Exposure of islets isolated from mice knocked out for either the  $\beta 2$  or the  $\alpha 7$  subunit of nACh receptors to the same cytokines showed that nicotine significantly decreased cytokine-induced  $\beta$ -cell apoptosis also in absence of the  $\beta 2$  subunit. In contrast, this protection was lost in islets isolated from mice knocked out for the  $\alpha 7$  subunit, indicating that the  $\alpha 7$  subunit is necessary for the action of nicotine. To confirm the importance of this subunit, we pre-incubated islets isolated from WT mice to choline, a specific agonist of this subunit. We found that this substance significantly decreased cytokine-induced  $\beta$ -cell death. Finally, measurement of nitrite accumulation in the culture media showed that pre-incubation with nicotine did not alter the production of NO by  $\beta$ -cells, indicating that cholinergic agonists did not interfere with the signaling pathways underlying cytokine receptors.

**Conclusion:** Our results show that activation of the  $\alpha 7$  subunit of nACh receptors, a subunit thought to be part of the cholinergic anti-inflammatory pathway and previously implicated in the regulation of cell death, decreased  $\beta$ -cell apoptosis induced by a cocktail of cytokines thought to mimic the environment of a  $\beta$ -cell at the onset of T1DM. This effect was not linked to alteration of NO production by  $\beta$ -cells, an event occurring early in the signaling pathway connecting cytokine signaling and apoptosis. This opens the interesting perspective of a pharmacological modulation of  $\beta$ -cell death to prevent the massive destruction leading to T1DM.

### Interleukin-6 potentiates the cytotoxic actions of both interleukin-1 $\beta$ and palmitate in pancreatic beta cells

M.A. Russell, N.G. Morgan;

Institute of Biomedical and Clinical Science, Peninsula College of Medicine and Dentistry (University of Exeter), Plymouth, UK.

**Background and aims:** Interleukin (IL)-6 and IL-1 $\beta$  are elevated within the islet milieu in human type 2 diabetes and may contribute to the low grade inflammation associated with this condition. IL-6 has well-recognised actions on pancreatic  $\alpha$ -cells and it has also been implicated in the development of insulin resistance at extra-pancreatic sites. However, the effect of this cytokine

on the viability of  $\beta$ -cells has received relatively little attention. Therefore, in the current work we have studied this.

**Materials and methods:** INS-1E cells were used as a model system but some experiments were also repeated with isolated human islets. Cell viability was assessed by flow cytometry following propidium iodide staining, whilst nitrite levels were determined by Griess assay. Data are presented as mean values ( $\pm$  SEM).

**Results:** The IL-6 receptor comprises two protein subunits (IL-6Ra and GP130) and the expression of these molecules was studied at the mRNA level by RT-PCR, using RNA prepared from INS-1E cells and human islets. Both subunits were expressed. Functionality of the receptor was confirmed by treatment of cells with IL-6. This resulted in enhanced tyrosine phosphorylation of the transcription factor, STAT3 within 15 minutes. Changes in phosphorylation of a second STAT protein, STAT6, are not typically associated with IL-6 mediated responses but, surprisingly, phosphorylation of STAT6 was also increased upon exposure to IL-6 in INS-1E cells. Exposure of INS-1E cells to IL-6 alone did not influence their viability, however the cytokine potentiated the cytotoxic effects of IL-1 $\beta$  (IL-1 $\beta$ :  $14.3 \pm 0.2$  % dead cells, IL-1 $\beta$  + IL-6:  $22.2 \pm 0.7$  %,  $p < 0.001$ ). Similarly, the response to a pro-inflammatory cytokine mix (pro:  $16.3 \pm 0.3$  % dead cells, pro + IL-6:  $22.7 \pm 0.7$  %,  $p < 0.001$ ) the saturated fatty acid, palmitate (palm:  $37.4 \pm 0.8$  % dead cells; palm + IL-6:  $44.3 \pm 0.3$  %,  $p < 0.001$ ) and serum withdrawal (serum free:  $45.5 \pm 1.1$  % dead cells, IL-6:  $60.7 \pm 1.3$  %,  $p < 0.001$ ) was also increased by IL-6. Nitrite production (an index of nitric oxide formation) was not elevated when cells were treated with IL-6 alone, whereas IL-1 $\beta$  caused a rise in nitrite formation and this response was potentiated by IL-6 (IL-1 $\beta$ :  $17.5 \pm 0.3$   $\mu$ M nitrite, IL-1 $\beta$  + IL-6:  $21.8 \pm 0.4$   $\mu$ M,  $p < 0.001$ ). We, and others, have shown that the anti-inflammatory cytokines IL-4 and IL-13 can exert cytoprotective effects in  $\beta$ -cells but it is not known whether they influence viability in the presence of IL-6. We found that both IL-4 and IL-13 improved the viability of cells treated with IL-6 and IL-1 $\beta$  (IL-1 $\beta$  + IL-6:  $35.3 \pm 0.9$  % dead cells, IL-1 $\beta$  + IL-6 + IL-4:  $29.4 \pm 0.9$  %,  $p < 0.001$ , IL-1 $\beta$  + IL-6 + IL-13:  $29.4 \pm 1.4$  %,  $p = 0.002$ ). Nitrite production under these conditions was also attenuated (IL-1 $\beta$  + IL-6 + IL-4:  $85.1 \pm 1.9$  % of nitrite produced following IL-6 + IL-1 $\beta$  treatment,  $p = 0.005$ ; IL-1 $\beta$  + IL-6 + IL-13:  $77.3 \pm 2.5$  %,  $p < 0.001$ ).

**Conclusion:** IL-6 augments the cytotoxic effects of pro-inflammatory cytokines, serum withdrawal and the saturated fatty acid palmitate in pancreatic  $\beta$ -cells. Since pancreatic islet cells may be exposed to elevated levels of IL-1 $\beta$ , IL-6 and fatty acids in type 2 diabetes, these may act in combination to promote a reduction in  $\beta$ -cell mass thereby exacerbating the condition. Anti-inflammatory cytokines (IL-4 and IL-13) antagonised the loss of viability in cells exposed to IL-6, suggesting that the precise cytokine milieu will be important in determining the ultimate fate of the  $\beta$ -cells *in vivo*.

493

### Activities and modulation of the proteasome in human pancreatic islets

M. Bugliani, F. Syed, M. Suleiman, F. Filippini, U. Boggi, L. Marselli, P. Marchetti;

University of Pisa, Italy.

**Background and aims:** The proteasome (Prot) is responsible of the proteolytic activity of the ubiquitin-proteasome system, that degrades unneeded or damaged proteins. Sparse data in clonal cell lines and rodent models suggest that Prot alterations may be associated with changes in beta cell function and survival. In this study we assessed the activities of Prot in human pancreatic islets and their regulation by several agents and conditions, including the presence of type 2 diabetes (T2D).

**Materials and methods:** Islets were isolated from 16 non-diabetic (ND; age  $67 \pm 16$  yrs, males/females 8/8, BMI  $25.2 \pm 1.6$  kg/m<sup>2</sup>) and 12 T2D (age  $74 \pm 6$  yrs, males/females 10/2, BMI  $27.5 \pm 2.39$  kg/m<sup>2</sup>) subjects. Proteolytic (trypsin-like, chymotrypsin-like and caspase-like) activities were measured by luminometric methods in whole islets or isolated (by affinity matrix beads) proteasome and the effects were evaluated of 0.5 mM palmitate (24h incubation), cytokines (IL-1 $\beta$ , 50 U/ml and IFN  $\gamma$ , 1000 U/ml, 24h incubation), presence of T2D and exposure to 2.4  $\mu$ g/ml metformin or 10 ng/ml GLP-1. Glucose-stimulated insulin secretion was assessed by batch incubation.

**Results:** All the proteasome activities were found in human islets and confirmed with isolated proteasome. In ND islets, chymotrypsin- and caspase-like activities were 2-fold (or more) higher than trypsin-like activity. Palmitate exposure decreased proteasome activities by 30-40% ( $p < 0.05$ ) and cytokines induced a 40% increase of trypsin-like activity ( $p < 0.01$ ). In T2D islets all the activities (in particular the trypsin-like) were reduced of 30-50% ( $p < 0.05$  or

less) compared to ND islets. Incubation (24h) of T2D islets with metformin or, more markedly so, GLP-1 determined a significant ( $p<0.05$ ) 20–40% increase of trypsin-like activity, which was associated with improved ( $p<0.05$ ) glucose-stimulated insulin secretion (stimulation index from  $1.5\pm0.2$  in untreated T2D islets to  $1.8\pm0.3$  after metformin and  $1.9\pm0.3$  after GLP-1).

**Conclusion:** These results show the presence of all the Prot activities in human islets, that are differently modulated by stressors such as palmitate or cytokines; Prot activities are reduced in T2D islets, and can be increased by some antidiabetic drugs (metformin and GLP-1), an effect that is associated with improved insulin secretion. Therefore the proteasome may play an important role in the pathophysiology of the beta cell and in its protection by pharmacological intervention.

## 494

### Transcription and activity of the proteasome are induced by pro-inflammatory cytokines, and proteasome expression is inhibited by HDAC and deubiquitinase inhibition

M. Lundh<sup>1,2</sup>, A. Choudhary<sup>2,3</sup>, D.H.C. Chou<sup>4</sup>, A. Tang<sup>2</sup>, T. Mandrup-Poulsen<sup>1,5</sup>, B. Wagner<sup>2</sup>;

<sup>1</sup>Department of Biomedical Sciences, University of Copenhagen, Denmark,

<sup>2</sup>Broad Institute of MIT and Harvard, Cambridge, USA, <sup>3</sup>Society of Fellows, Harvard University, Cambridge, USA, <sup>4</sup>Massachusetts Institute of Technology, Cambridge, USA, <sup>5</sup>Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Selective destruction of pancreatic beta-cells causes Type 1 diabetes mellitus (T1DM). Pro-inflammatory cytokines e.g. IL-1 $\beta$ , TNF $\alpha$  and IFN $\gamma$  are secreted by infiltrating immune cells and induce beta-cell apoptosis. Cytokine-induced beta-cell apoptosis is prevented by inhibition of lysine deacetylases (KDACs) or by the inhibition of deubiquitinases (DUBs). Several lines of evidence indicate the importance of the proteasome in cytokine-induced beta-cell death, but the regulation of the expression and the mechanism of activation of the proteasome are unknown. Furthermore, it is unknown whether the protective effects of KDAC and DUB inhibition are mediated via effects on the proteasome.

**Materials and methods:** INS-1E cells were exposed to a combination of pro-inflammatory cytokines (IL-1 $\beta$ , TNF $\alpha$  and IFN $\gamma$ ) for 3, 6, 9, 12 or 24 hours in the presence or absence of the class I KDAC inhibitor MS275 (5  $\mu$ M), a putative DUB inhibitor identified by screening (10  $\mu$ M) or vehicle. Expression of four selected proteasomal genes was examined by qPCR. Proteasomal activity was determined by a selective proteasome assay (Promega). MG132, a proteasome inhibitor, was used as a positive control.

**Results:** Pro-inflammatory cytokines significantly induced the expression of the proteasomal subunits, PSMA2 (170%), PSMA7 (212%), PSME1 (429%) and PSMB10 (1050%) in a time-dependent manner ( $n=4$ ,  $p<0.01$ , ANOVA, post hoc t-test). This induction was partially reversed by MS275 and to a lesser extent by the DUB inhibitor ( $n=4$ ,  $p<0.05$ , ANOVA, post hoc t-test). Furthermore, cytokines induced proteasomal activity after one hour persisting in the ensuing twelve hour incubation period (129%, 22 independent wells,  $p<0.01$ , ANOVA, post hoc t-test). Interestingly, this increase in activity was not affected by either KDAC inhibition or DUB inhibition.

**Conclusion:** The expression and activation of the proteasome is induced by pro-inflammatory cytokines in INS-1 cells, but only cytokine-induced gene expression is counteracted by protective small molecules. These data suggest that the protective effects of HDAC and DUB inhibition are not mediated by preventing cytokine-induced proteasomal activity.

#### The Glutamate transporter GLT1/EAAT2: a promising target to arrest beta cell dysfunction and death in diabetes mellitus

A.M. Davalli<sup>1</sup>, E.S. Di Cairano<sup>2</sup>, M. Iaquinto<sup>2</sup>, S. Moretti<sup>2</sup>, C. Bazzini<sup>3</sup>, S. La Rosa<sup>4</sup>, F. Bertuzzi<sup>5</sup>, F. Folli<sup>6</sup>, C. Perego<sup>2</sup>;

<sup>1</sup>Internal Medicine, Diabetes & Endocrinology, San Raffaele Hospital, Milan, Italy, <sup>2</sup>Dept of Molecular Science Applied to Biosystems, University of Milano, Italy, <sup>3</sup>Biomolecular Science and Biotechnology, University of Milano, Italy, <sup>4</sup>Anatomical Pathology, Ospedale di Circolo Varese, Italy, <sup>5</sup>Niguarda Cà Granda Hospital, Milano, Italy, <sup>6</sup>Dept. of Medicine Diabetes Division, University of Texas Health Science Center, USA.

**Background and aims:** The clinical course of Diabetes Mellitus is characterized by a progressive decline in  $\beta$ -cell function and mass. Understanding the causes for  $\beta$ -cell failure and death is therefore of capital importance to develop new and more effective therapeutic strategies. We have recently shown that glutamate, an important signalling molecule in islet of Langerhans, represents a new, previously unknown, insult for  $\beta$ -cells. Noteworthy, increased glutamate levels have been found in sera of T1D and T2D subjects, suggesting that abnormal glutamate homeostasis may be involved in diabetes pathogenesis. Our previous work demonstrates that the glutamate transporter GLT1 is a key regulator of glutamate clearance in the islet and in the control of  $\beta$ -cell integrity and a candidate target for pharmacological intervention. Aim of the proposed research is to verify whether GLT1 dysfunction may play a role in diabetes mellitus pathogenesis.

**Materials and methods:** The localization of GLT1 in human pancreases from 5 healthy subjects (age:  $69\pm7$  years; M/F:3/2) and 8 T2DM patients (age:  $67\pm8$  years; M/F:5/3; disease duration range 1.5–30 years) was analysed by immunohistochemistry. The molecular mechanisms responsible for GLT1 alterations were investigated in human islet preparations exposed for 3 days to metabolic insults (chronic hyperglycaemia 16.7 mM glucose; pro-inflammatory cytokines TNF $\alpha$ , IL $\beta$ , IFN $\gamma$ ) by means of western blotting, uptake and immunofluorescence experiments. Data are expressed as mean value $\pm$ SE. The study has been reviewed by the local ethics committee.

**Results:** In healthy control pancreases GLT1 staining was detected exclusively in the islet, and confined to the plasma membrane of  $\beta$ -cells. In contrast, in 5 of 8 T2DM pancreases GLT1 staining was mainly detected in intracellular compartments. Interestingly the 5 patients showing complete GLT1 internalization were those treated with insulin likely because of secondary failure to the oral antidiabetic agents. When exposed to high glucose, the total GLT1 expression of cultured human islets remained stable ( $94\pm6\%$  of 5.5 mM glucose), however, the transporter translocated from the cell membrane into intracellular vesicular compartments. Accordingly, GLT1 transport activity measured by means of [ $^3$ H]D-glutamate uptake was inhibited by  $25\pm5\%$  as compared to 5.5 mM glucose ( $p<0.05$ ). Three days incubation with pro-inflammatory cytokines alone (100U/ml TNF $\alpha$ ) or in combination (100U/ml TNF $\alpha$ , 50U/ml IL $\beta$ , 100U/ml IFN $\gamma$ ) caused a significant reduction of GLT1 expression ( $65\pm8\%$  and  $53\pm3\%$  as compared to untreated islets, respectively,  $p<0.05$ ).

**Conclusion:** Abnormal GLT1 expression and function may be an early event in diabetes pathogenesis and it may contribute significantly to  $\beta$ -cell loss. Development of drugs targeting GLT1 may represent a novel approach to diabetes treatment.

### Activation of 5-HT receptors 2a and 2b promotes viability and potentiates glucose stimulated insulin release in a clonal beta cell (INS 832/13) line

A. Balhuizen, H. Bennet, L. Groop, M. Fex;

Department of Clinical Sciences, Lund University, Malmö, Sweden.

**Background and aims:** The role of serotonin (5-HT) in glucose homeostasis and its effect on insulin secretion is not yet fully understood 5-HT has been shown to modulate insulin secretion from islets of Langerhans either through serotonylation of GTPases or by binding to G-protein coupled receptors; these receptors display either inhibitory or stimulatory effects on

glucose stimulated insulin secretion (GSIS). The serotonin 2 family, signals via Gq, phospholipase-C, and consists of three subtypes: 2a, 2b and 2c. These are all known to have central effects on glucose homeostasis by regulation of food intake and energy expenditure. In peripheral tissues, the 5-HT<sub>2</sub> receptor family has been shown to have proliferative and cyto-protective properties in neurons and cardiomyocytes, respectively. With this notion, we will investigate if signalling through these receptors can protect beta cells against gluco/lipotoxicity and/or cytokine induced cell death.

**Material and methods:** Quantitative (Q)PCR was used to detect receptor expression from mRNA isolated from the (physiologically relevant) clonal beta cells (INS(832/13). Expression was detected with primers for HTR2a and HTR2b and HTR2c and compared against internal reference genes (HPRT, POLR2A and PPIA). The following agonists were used: 5-HT<sub>2a</sub>, TCB-2 (0–500 μM) and for 5-HT<sub>2b</sub> α-Methyl serotonin maleate salt (α-MET) (0–100 μM). INS(832/13) cells were incubated with cytokines: rrIL-1β10 ng/ml, rrTNFα 16 ng/ml and rrIFNγ 7.2 ng/ml or a combination of Palmitate (0.6 mM) and high glucose (30 mM). Insulin concentrations were measured with Mouse Insulin ELISA and protein content with BCA. Apoptotic cells were stained for Annexin-V and Propidium Iodide and detected with a FACS-system. INS(832/13) cell proliferation rate was detected with a Ki-67 antibody and quantified with a FACS-system.

**Results:** INS 832/13-cells express 5-HT<sub>2a</sub> and 5-HT<sub>2b</sub> but not 5-HT<sub>2c</sub> receptors. Long term incubation with agonists TCB-2 and α-MET showed a tendency towards an increase in expression of both receptors, suggesting a regulatory feedback loop on receptor signalling and expression of receptors. Moreover, α-MET and TCB-2, potentiated glucose stimulated insulin secretion in a concentration-dependent manner; TCB-2 displayed an EC<sub>50</sub> of 5.8·10<sup>-6</sup> at 16.7 mM glucose and 100 μM TCB-2 increased GSIS with a p-value of 0.007. In addition, at 16.7 mM glucose, 5 μM α-MET increased GSIS with a p-value of 0.0016. Preliminary data indicates that α-MET and TCB-2 decrease the apoptotic rate of INS-cells incubated with proinflammatory cytokines and during gluco/lipotoxic conditions.

**Conclusion:** Our results show that serotonin receptors 5-HT<sub>2a</sub> and 5-HT<sub>2b</sub> are expressed in INS(832/13) cells and when activated these receptors are able to potentiate glucose stimulated insulin secretion. In addition, α-MET via the 5-HT<sub>2b</sub> receptor display cell protective effects against both proinflammatory cytokines and gluco/lipotoxic conditions. The present study contributes to the understanding how serotonin affects the pancreatic beta cell, and how the 5-HT<sub>2</sub> receptor family may promote beta cell viability and function in type 2 diabetes.

### Galectin-3 deficiency confers resistance to cytokine-induced apoptosis of pancreatic islets - role of mitochondrial pathway

I. Nikolic<sup>1</sup>, T. Saksida<sup>1</sup>, N. Zdravkovic<sup>2</sup>, I. Stojanovic<sup>1</sup>, M.L. Lukic<sup>2</sup>, S. Stosic-Grujicic<sup>1</sup>

<sup>1</sup>Immunology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Serbia, <sup>2</sup>Center for Molecular Medicine, Faculty of Medicine, University of Kragujevac, Serbia.

**Background and aims:** Galectin-3 (Gal-3) is β-galactoside-binding lectin expressed in variety of tissues and cell types and has diverse functions, including promotion of inflammatory response and triggering apoptosis. However, the precise role of Gal-3 in type 1 diabetes remains obscure. Since we have previously shown that Gal-3 deficient (Gal-3<sup>-/-</sup>) mice are relatively resistant to diabetogenesis induced by multiple low doses of streptozotocin, the aim of this study was to examine the effect of Gal-3 deficiency at the level of pancreatic islets in the setting seen during diabetes pathogenesis.

**Materials and methods:** We exposed mouse pancreatic islets isolated from Gal-3<sup>-/-</sup> and WT (C57BL/6) mice by collagenase digestion to proinflammatory cytokines (IL-1β+IFN-γ+TNF-α, 10 ng/ml each) and analysed their survival. In addition, 30 minutes before adding cytokines islets from WT mice were incubated in the presence or absence of chemical Gal-3 inhibitors: chemical inhibitor (Td131\_1, 10 mM) or natural competitor β-D-lactose monohydrate (50 mM). After incubation, β-cell apoptosis was measured by histone-DNA ELISA. Expression profiles of various related genes were determined at mRNA and protein levels by real time PCR (RT-PCR) and Western blot, respectively.

**Results:** Deficiency of Gal-3 either hereditary or induced through application of inhibitors promotes better survival of pancreatic islets after apoptotic stimulus. We further analysed molecular mechanisms involved in protection of Gal-3<sup>-/-</sup> islets from cytokine-induced apoptosis. The lack of Gal-3 impairs

activation of caspase-3 after cytotoxic stimulus. Protein level of activated caspase-3 after cytotoxic stimulus was lower in Gal-3<sup>-/-</sup> islets compared to WT islets. Also, Gal-3 deletion alters the pattern of expression of pro- and anti-apoptotic molecules determined by RT-PCR analysis of stimulated islets. mRNA levels of anti-apoptotic molecules Bcl-2 and Bcl-X<sub>L</sub> were up-regulated in Gal-3<sup>-/-</sup> islets compared to WT islets, while there was no difference in expression of pro-apoptotic Bax. Western blot analysis confirmed this shift of pro- and anti-apoptotic molecules in favour of anti-apoptotic molecules after cytotoxic stimulus. Furthermore, preserved viability of Gal-3<sup>-/-</sup> islets coincided with up-regulation of phospho-ERK1/2, a pro-survival kinase.

**Conclusion:** This study suggests that Gal-3 is involved in pancreatic islets apoptosis in the inflammatory milieu that occurs during diabetes pathogenesis and implicates impairment of mitochondrial apoptotic pathway as a key event in protection from beta cell apoptosis in the absence of Gal-3.

## 498

### Cytoprotective effect of prostacyclin against cytokine toxicity in insulin-secreting cells depends on the activation of its extracellular receptors

E. Gurgul-Convey, K. Hanzelka, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

**Background and aims:** The overexpression of prostacyclin synthase (PGIS), the enzyme synthesizing the antiinflammatory prostaglandin I<sub>2</sub> (prostacyclin), has been shown to protect pancreatic beta cells against cytokine toxicity via inhibition of the cytokine-mediated NFκB activation and nitrosative stress. It remains unknown if prostacyclin produced by PGIS acts only within or if it must be released from the cell of origin and act via the activation of its extracellular receptors. Therefore the aim of this study was to analyze the fashion of the action of prostacyclin in insulin-secreting cells.

**Materials and methods:** Insulin-secreting INS1E cells were stably transfected either with an empty pcDNA3.1 vector (INS1E-control) or with the pcDNA3.1-hPGIS (INS1E-PGIS). Cells were treated with IL-1β 600 U/ml or with a cytokine mix (IL-1β 60 U/ml, TNFα 185 U/ml, IFNγ 14 U/ml) in the absence or presence of a stable prostacyclin analogue (iloprost) or the prostacyclin receptor blocker (10 nM CAY10441) for 24 h. Thereafter proliferation was measured by a BrdU ELISA, caspase-3 by flow cytometry, cAMP by ELISA, NFκB and iNOS-promoter by SEAP reporter gene assays, nitrite by Griess method and ATP by ATPlite assay.

**Results:** INS1E-PGIS cells had a significantly higher content of ATP in comparison with INS1E-control cells (5.7 vs. 2.8 nmol/mg protein). Cytokines reduced ATP content in INS1E-control cells (IL-1β 50%, cytokine mix: 75% vs. 100% untreated). This reduction was counteracted by iloprost and PGIS overexpression and enhanced by CAY10441. The cAMP content in INS1E-control cells was 13±1, while in INS1E-PGIS cells 22±2 pmol/mg protein. CAY10441 reduced the cAMP content in INS1E-PGIS cells (9±1 pmol/mg protein). IL-1β and a cytokine mix induced caspase-3 activation in INS1E-control cells (IL-1β: 151%, cytokine mix: 258% vs. 100% untreated). Iloprost inhibited and PGIS overexpression prevented this activation (IL-1β: 81%, cytokine mix: 118% vs. 100% untreated), and this was reversed by CAY10441. The basal proliferation rate of INS1E-PGIS cells was significantly higher as in INS1E-control cells (140 vs. 100% in INS1E-control cells). Cytokines reduced proliferation of INS1E-control cells (IL-1β 60%, cytokine mix: 70% vs. 100% untreated). The cytokine-mediated inhibition of cell proliferation was weaker in INS1E-PGIS cells, but was enhanced by CAY10441. PGIS overexpression protected also against cytokine-stimulated NFκB activation, iNOS promoter induction and nitrite formation (INS1E-control NFκB: IL-1β 7-fold, cytokine mix 5-fold; INS1E-PGIS: IL-1β 2-fold, cytokine mix: 3-fold; INS1E-control iNOS promoter IL-1β 8-fold, cytokine mix 10-fold; INS1E-PGIS: IL-1β 3.5-fold, cytokine mix 4-fold; INS1E-control: nitrite IL-1β 37, cytokine mix 100; INS1E-PGIS: IL-1β 7, cytokine mix 14 pmol/μg protein). This protection was reduced by CAY10441.

**Conclusion:** The prostacyclin analogue and PGIS overexpression protected insulin-secreting cells against cytokine toxicity, and this cytoprotective effect correlated with an increased content of ATP and cAMP. The protection provided by prostacyclin strongly, but not exclusively, depends on the prostacyclin-induced activation of the extracellular prostacyclin receptors. Thus chemical prostacyclin analogues may be drug candidates for protection of beta cells against cytokine toxicity in type 1 diabetes.

**The adipocytokines Nampt and vaspin have no effect on beta cell survival but potentiate glucose stimulated insulin secretion**

K. Stolz<sup>1</sup>, R. Spinnler<sup>2</sup>, T. Gorski<sup>2</sup>, S. Lau<sup>2</sup>, S. Schuster<sup>2</sup>, A. Garten<sup>2</sup>, J. Kratzsch<sup>3</sup>, P. Kovacs<sup>4</sup>, J. Heiker<sup>5</sup>, A. Beck-Sickinger<sup>6</sup>, E. de Koning<sup>7</sup>, A. Körner<sup>2</sup>, W. Kieß<sup>2</sup>, K. Maedler<sup>1</sup>;

<sup>1</sup>Centre for Biomolecular Interactions, University of Bremen, <sup>2</sup>University Hospital for Children and Adolescents, Center for Pediatric Research Leipzig (CPL), <sup>3</sup>Institute of Laboratory Medicine, Leipzig, <sup>4</sup>Interdisciplinary Centre for Clinical Research, Leipzig, Germany, <sup>5</sup>Department of Internal Medicine, Leipzig, Germany, <sup>6</sup>Institute of Biochemistry, Leipzig, <sup>7</sup>Leiden University Medical Center, Leiden, Netherlands.

**Background and aims:** Obesity is associated with a dysregulation of beta-cell and adipocyte function. The molecular interactions between adipose tissue and beta-cells are not yet fully elucidated. We investigated, whether the newly identified adipocytokines Nampt and vaspin, which all have been independently associated with obesity and T2DM directly influence beta-cell survival and function.

**Materials and methods:** The effect of the adipocytokines on viability of INS-1E cells was assessed by WST-1 assay. Apoptosis was measured by Annexin V/PI, TUNEL assay or by activated caspase-3. Adenylate kinase release was determined to assess cytotoxicity. Chronic and acute effects of the adipocytokines on insulin secretion were assessed by glucose stimulated insulin secretion in human islets.

**Results:** While stimulation of beta-cells with the cytokines IL-1 $\beta$ , TNF $\alpha$  and IFN- $\gamma$  or palmitate significantly decreased viability, Nampt and vaspin showed no direct effect on viability in INS-1E cells or in human islets, neither alone nor in presence of pro-diabetic conditions (elevated glucose concentrations and palmitate or cytokines). At chronic conditions over 3 days of culture, Nampt, its enzymatic product nicotinamide Mononucleotide (NMN) and vaspin had no effects on insulin secretion. In contrast, both adipocytokines potentiated glucose stimulated insulin secretion acutely during 1h incubation of human islets.

**Conclusion:** Nampt and vaspin did not influence beta-cell viability nor apoptosis but acutely potentiated glucose stimulated insulin secretion.

**Sodium tungstate promotes beta cell survival in IRS2-deficient mice model**

J. Oliveira<sup>1,2</sup>, S. Rebuffat<sup>1,2</sup>, A. García<sup>1,2</sup>, A. Novials<sup>1,2</sup>, R. Gasa<sup>1,2</sup>, R. Gomis<sup>1,2</sup>;

<sup>1</sup>IDIBAPS/Hospital Clinic, <sup>2</sup>Ciberdem, Barcelona, Spain.

The control of pancreatic  $\beta$ -cell growth and survival plays an essential role in the pathogenesis of type 2 diabetes. The failure of  $\beta$ -cell mass to adequately expand in settings of insulin resistance results in the appearance of glucose intolerance and type 2 diabetes. The molecular mechanisms involved in this failure are poorly known. Nevertheless, it is well accepted that signal transduction via Insulin/Insulin growth factor/IRS-2 is critically involved in this process. Indeed, the ablation of the IRS-2 gene in mice results in impaired  $\beta$ -cell survival and the subsequent development of a phenotype with characteristics of type-2 diabetes. Prior work by our group has described sodium tungstate as a possible pharmacological modulator of  $\beta$ -cell mass. Here, we investigated if sodium tungstate administration could reverse the diabetic phenotype of IRS-2 knockout mice. 10-week old wild type (WT) and knockout IRS2 C57Bl/6 (Irs2<sup>-/-</sup>) mice were given a solution of 2mg/ml of sodium tungstate (treated groups) or distilled water (untreated groups) for 21 days. During this period, basal and postprandial blood glucose levels were recorded.  $\beta$ -cell mass was quantified using immunohistochemical and morphometric analysis. Apoptotic cell death was determined by cleaved caspase 3 staining. Global gene expression profiles were analyzed in isolated pancreatic islets using mouse genome Affymetrix arrays and protein expression was assessed using Panorama Cell signaling Antibody arrays. The administration of sodium tungstate significantly decreased basal glycemia (from 221 $\pm$ 26 to 134 $\pm$ 23 mg/dl, n=9) and improved glucose tolerance in Irs2<sup>-/-</sup> mice relative to untreated Irs2<sup>-/-</sup> while no changes were observed in WT animals. As expected, untreated Irs2<sup>-/-</sup> mice showed pronounced hyperglycaemia and reduced  $\beta$ -cell mass (0.28 $\pm$ 0.2 vs 0.94 $\pm$ 0.2 mg, p<0.001, untreated Irs2<sup>-/-</sup> vs WT) owing to smaller size islets containing fewer  $\beta$ -cells. Remarkably, the treatment with tungstate prevented the loss of  $\beta$ -cell mass in Irs2<sup>-/-</sup> mice (0.61 $\pm$ 0.3 mg vs 0.28 $\pm$ 0.2 mg, p<0.05, treated vs untreated Irs2<sup>-/-</sup>), which correlated

with decreased  $\beta$ -cell apoptosis (2.6%  $\pm$ 0.01 vs 17.2%  $\pm$ 0.14, p<0.05, treated vs untreated Irs2<sup>-/-</sup>) and increased  $\beta$ -cell proliferation (0.45% $\pm$ 0.0084 vs 0.01% $\pm$ 0.0001). These data was supported by transcriptomic analysis of isolated pancreatic islets that revealed downregulation of several apoptosis and inflammation-related genes (such as Gasdermin and Cidea) in treated Irs2<sup>-/-</sup> relative to untreated Irs2<sup>-/-</sup> mice. Interestingly, 30% of these genes were upregulated in the Irs2<sup>-/-</sup> untreated group and downregulated by tungstate treatment. Furthermore, protein expression analysis confirmed the inhibition of cellular apoptosis pathways. Specifically, Fas (CD95/Apo-1) and FADD proteins, which are involved in death receptor induced apoptosis, and caspase 9, an initiator caspase linked to the mitochondrial death pathway, were found to be inhibited by tungstate treatment in Irs2<sup>-/-</sup> mice. Our findings demonstrate that sodium tungstate treatment ameliorates the diabetic phenotype of IRS-2 knockout mice, likely through inhibition of  $\beta$ -cell loss by repressing the apoptotic machinery. Further experiments are currently being performed in order to unravel the molecular mechanisms underlying the effects of tungstate on  $\beta$ -cell survival.

### Non-invasive in-vivo analysis of beta cell function and mass by MRI

A. Meyer<sup>1</sup>, E. Kuestermann<sup>2</sup>, K. Stolz<sup>1</sup>, J. Bergemann<sup>1</sup>, W. Dreher<sup>2</sup>, K. Maedler<sup>1</sup>;

<sup>1</sup>Centre for Biomolecular Interactions, <sup>2</sup>FB2, MR imaging & in-vivo spectroscopy, University of Bremen, Germany.

**Background and aims:** Diabetes diagnostic, therapy and research would strongly benefit from non-invasive methods of analyzing pancreatic  $\beta$ -cell mass (BCM). Besides BCM, the capacity of the  $\beta$ -cell to produce sufficient amounts of insulin depends on  $\beta$ -cell function. Thus, we aimed to develop a strategy to monitor the functional  $\beta$ -cell mass by measuring manganese (Mn2+) uptake into  $\beta$ -cells by T1-weighted in-vivo Magnet Resonance Imaging (MRI). Divalent manganese ions (Mn2+), like Ca2+, enter metabolically active  $\beta$ -cells glucose-dependently through voltage-gated calcium channels, which open in response to a rise in extracellular glucose and the subsequent closure of ATP-sensitive K+ channels.

**Materials and methods:** C57Bl/6J mice were fed a normal diet (ND) or high fat/high sucrose diet (HFD) over 6 weeks. Glucose tolerance was monitored by intraperitoneal glucose tolerance tests and classical measures of  $\beta$ -cell mass in isolated pancreases were performed. For MRI imaging, 2 g/kg Glucose was injected i.p., followed by intravenous MnCl2 (i.v.). Respiratory-triggered 3D-“Snapshot FLASH” images were obtained using a 7T Bruker Biospec system (70/20 USR) with inversion recovery preparation for kinetic measurements of the Mn2+-uptake. The scan-TR was 6 s to ensure full relaxation and to avoid any breathing rate dependent T1-effects. Pancreas signal was normalized to the final liver signal.

**Results:** The comparison of temporal signal changes upon i.v. injection of manganese ions reveals strong differences between ND and HFD fed mice. During the first 2 weeks of the diet a 1.3-fold higher Mn2+-signal could be detected in the pancreas of the HFD compared to the ND group, accordingly, also glucose tolerance was improved in the HFD fed mice. After 3 weeks of diet, comparable MRI signals were detected in both groups together with a similar glucose tolerance. After 6 weeks of diet the signal intensity of the pancreas in the HFD was 1.4-fold lower than in the ND group ( $p < 0.05$ ). At the same time, glucose tolerance as well as insulin secretion during the ipGTT was impaired, while  $\beta$ -cell mass was 1.5-fold increased in the HFD group ( $p < 0.05$ ), indicating the compensatory growth of  $\beta$ -cells in response to the HFD after 6 weeks. These data show, that MRI using Mn2+ analyses the functional rather than the total  $\beta$ -cell mass. No long-term effects of Mn2+ on glucose tolerance, even after multiple injections were observed.

**Conclusion:** Our optimized protocol for T1-weighted imaging of the mouse abdomen fulfills the requirements of non-invasive MR imaging. The analysis of glucose-dependent Mn2+-uptake from the mouse pancreas is a technique, which can be used in-vivo to assess the functionality of both grafted and endogenous pancreatic islets.

### Lysosomal acid lipase and lipophagy are constitutive negative regulators of glucose stimulated insulin secretion from pancreatic beta cells

G. Pearson<sup>1</sup>, N. Mellett<sup>2</sup>, P. Bourbon<sup>3</sup>, C. Cosner<sup>3</sup>, P. Helquist<sup>3</sup>, P. Meikle<sup>2</sup>, T. Biden<sup>1</sup>;

<sup>1</sup>Garvan Institute of Medical Research, Sydney, Australia, <sup>2</sup>Baker IDI, Melbourne, Australia, <sup>3</sup>University of Notre Dame, USA.

**Background and aims:** Glucose stimulated insulin secretion (GSIS) involves both initiation and amplification pathways. Lipolytic breakdown of endogenous lipid pools contributes to the amplification phase, mediated by acute activation of neutral lipases. Chronic downregulation of autophagy (where macromolecules are delivered to the lysosome for degradation) also inhibits insulin secretion. More recently, it has been shown in other cell types, that endogenous lipid can be metabolised by autophagy (lipophagy) using lysosomal acid lipase (LAL). Our current aim was to investigate LAL in pancreatic beta cells, and its role in lipophagy and GSIS.

**Methods:** MIN6 cells were incubated for 24h with <sup>14</sup>C-palmitic acid, followed by glucose stimulation (2- or 20mmol/l glucose for 1h), and then subjected

to subcellular fraction to determine lipid localisation. GSIS was measured by insulin RIA in: MIN6 cells treated for 24h with 5 $\mu$ mol/l lalistat (LAL inhibitor); MIN6 cells transfected with atg7 siRNA; and mouse islets treated for 24h with 5mmol/l 3-methyladenine (3MA). Lipid composition in lalistat-treated MIN6 cells was measured using lipid GC-MS. Gene and protein expression changes were assessed with RT-PCR and Western blot. Statistical analysis was by one-way ANOVA with bonferroni post-test, unless otherwise stated.

**Results:** Incorporation of <sup>14</sup>C-palmitic acid into MIN6 cells showed that 15% of the total labelled lipid was localised to lysosomal fractions. RT-PCR and Western blot analysis showed abundant expression of LAL in MIN6 cells, mouse and human islets. GSIS was upregulated 1.8 fold in MIN6 cells pre-treated with lalistat (ng insulin/ug protein/h $\pm$ SEM: control 6.08 $\pm$ 0.53; lalistat 11.04 $\pm$ 0.58  $n=3$ ;  $P < 0.001$ ). Lalistat treatment of MIN6 cells increased neutral lipids (nmol/mg protein $\pm$ SEM,  $n=4$ ): cholesterol ester 6.7 fold (control 13.6 $\pm$ 2.62; lalistat 92.1 $\pm$ 11.4;  $P < 0.01$  t-test), triacylglycerol 1.7 fold (control 0.69 $\pm$ 0.12; lalistat 1.15 $\pm$ 0.14;  $P < 0.05$  t-test) and diacylglycerol 2 fold (control 5.71 $\pm$ 1.23; lalistat 11.8 $\pm$ 1.58;  $P < 0.05$  t-test). Diacylglycerol was further increased, approximately 2 fold ( $P < 0.01$  t-test), with 20mmol/l glucose after lalistat treatment. Inhibiting autophagy, with atg7 siRNA in MIN6 cells, resulted in a 1.5 fold increase in GSIS (ng insulin/ug protein/h $\pm$ SEM: control si 1.52 $\pm$ 0.12; atg7 si 2.26 $\pm$ 0.21  $n=3$ ;  $P < 0.01$ ). In mouse islets inhibiting autophagy with 3MA caused a 2 fold increase in GSIS (pg insulin/islet/h $\pm$ SEM: control 486.1 $\pm$ 199.1; 3MA 953.4 $\pm$ 230  $n=4$ ;  $p < 0.05$  paired t-test).

**Conclusion:** Our data suggests that lysosomal breakdown of lipids, via the action of LAL and potentially involving lipophagy, is a constitutive negative regulator of GSIS. This process could be mediated by depletion of substrate for the neutral lipases that are activated by glucose.

### Characterisation of pancreatic islets from two lines of selectively bred mice with different susceptibilities to high fat diet-induced glucose intolerance

M. Nagao, A. Asai, M. Kawahara, Y. Sato, Y. Nakajima, H. Sugihara, S. Oikawa;

Division of Endocrinology and Metabolism, Department of Medicine, Nippon Medical School, Tokyo, Japan.

**Background and aims:** Several animal models are currently used in the research field of type 2 diabetes. However, they could not explain the genetic factors for determining the susceptibility to diet-induced diabetes. We recently established two lines of mice with different susceptibilities (prone and resistant) to high fat diet (HFD)-induced glucose intolerance by selective breeding (designated SDG-P and SDG-R, respectively). Even before HFD feeding, SDG-P mice showed modestly higher blood glucose levels in OGTT relative to SDG-R mice. After receiving HFD, the glucose intolerance of SDG-P mice became more evident without hyperinsulinemia. In this study, we evaluated morphology and function of pancreatic islets from both mouse lines to investigate the heritable factors for determining the susceptibility to diet-induced glucose intolerance.

**Materials and methods:** Male mice of each strain fed HFD (32% energy as fat) for 5 weeks (from 5 to 10 weeks of age). Before and after HFD feeding (SDG-P; n=9, SDG-R; n=9, respectively), islets were isolated by collagenase perfusion. Islet morphology was evaluated under a stereomicroscope. Glucose- and KCl- induced insulin secretion (GSIS and KSIS) from the isolated islets were assessed *ex vivo* by batch incubation in media containing 16.7 mmol/l glucose and 34.8 mmol/l KCl, respectively. Gene expressions related to insulin secretion in the isolated islets were evaluated by real time quantitative PCR. All data are expressed as means  $\pm$  SEM. Mean values were compared using Student's *t* test.

**Results:** Before HFD feeding, more numbers of islets were yield from SDG-P mice than SDG-R mice (SDG-P vs. SDG-R;  $173 \pm 19$  vs.  $106 \pm 17$  islets/mouse,  $P=0.020$ ), whereas apparent islet size was not different ( $22.6 \pm 1.0$  vs.  $21.9 \pm 1.0 \times 10^3 \mu\text{m}^2/\text{islet}$ ,  $P=0.61$ ). After HFD feeding, no significant differences were observed in the number of isolated islets between the two strains ( $224 \pm 24$  vs.  $183 \pm 14$  islets/mouse,  $P=0.15$ ); however, apparent islet size of SDG-P mice became larger than that of SDG-R mice ( $31.7 \pm 1.2$  vs.  $22.4 \pm 0.6 \times 10^3 \mu\text{m}^2/\text{islet}$ ,  $P<0.001$ ). Regardless of whether it was before or after HFD feeding, GSIS and KSIS from the isolated islets from SDG-P mice were significantly lower than those from SDG-R mice. Before HFD feeding, GSIS and KSIS of SDG-P islets were  $43.9 \pm 4.3\%$  ( $P=0.024$ ) and  $63.4 \pm 4.9\%$  ( $P=0.007$ ) of SDG-R islets, respectively; after HFD feeding, they were  $45.2 \pm 3.6\%$  ( $P=0.001$ ) and  $45.8 \pm 2.8\%$  ( $P<0.001$ ), respectively. In addition, mRNA expression levels of GLUT-2 (before HFD, after HFD;  $P=0.024$ ,  $P=0.023$ ), PDX-1 ( $P=0.023$ ,  $P=0.014$ ), and Syntaxin-1a ( $P=0.059$ ,  $P=0.028$ ) were lower in SDG-P islets as compared with SDG-R ones both before and after the HFD feeding.

**Conclusion:** The HFD-induced glucose intolerance prone SDG-P mice showed spontaneous impairments of GSIS and KSIS in pancreatic islets. Although, hypertrophy was observed after HFD feeding in SDG-P islets, the compensation by beta-cell proliferation was insufficient to regulate glucose metabolism. Results of real time PCR analysis suggest that reduced gene expressions of glucose sensing, exocytosis, and transcription factor in SDG-P islets contribute to the insufficiency of insulin secretion and beta-cell proliferation. Taken together, these characteristics in pancreatic islets may determine the susceptibility to HFD-induced glucose intolerance.

**Background and aims:** Hyperglycemia and high fatty acids concentrations (*i.e.*, palmitic acid, PA, 16:0) are detrimental to  $\beta$ -cells. The combination of

both deteriorates  $\beta$ -cell function in a phenomenon termed glucolipotoxicity. Analysis of membrane phospholipids in INS-1E  $\beta$ -cells revealed a significant glucose-induced changes in the content of various saturated (SFA)-, mono-unsaturated (MUFA)- and poly-unsaturated fatty acids (PUFA). Of a particular interest is the release of arachidonic (AA, 20:4) and linoleic acids (LA, 18:2) into the cell interior. Both fatty acids undergo free radical-induced peroxidation and generate 4-hydroxynonenal (4-HNE), which at high levels becomes cytotoxic. The present study aimed at elucidating the contribution of phospholipid remodeling to glucolipotoxic interactions in  $\beta$ -cells.

**Materials and methods:** INS-1E cells were maintained at 5, 11 and 25 mM glucose for 48h, without or with PA (50–500  $\mu\text{M}$ ) added during the last 16h of incubation. The cells were then harvested, extracted and chemically-formed methyl-esters of fatty acids were analyzed by gas-chromatography. In parallel, glucose-stimulated insulin secretion (GSIS) and cell viability assays were performed. Western blot analysis of 4-HNE-histidine adducts was employed to estimate cell-associated 4-HNE.

**Results:** As expected, exposure of INS-1E cells to PA increased concentration-dependently its content in phospholipids. Concomitantly, an enhanced desaturation of PA to palmitoleic acid (16:1) increased the abundance of the latter in phospholipids. Otherwise, other glucose- and PA-induced changes in the abundance of fatty acids in phospholipids were additive. Of interest is the finding that PA significantly and concentration-dependently reduced AA and LA content in phospholipids, with maximal effects ( $\sim 40\%$  reduction) observed already after 2h incubation in the presence of 50–125  $\mu\text{M}$  PA at all glucose levels. Cell viability was not affected under these conditions and GSIS was nearly 30–40% higher than in the control cells. Cytotoxicity was apparent only in cells maintained at 11 or 25 mM glucose and exposed to 250–500  $\mu\text{M}$  of PA for 12–16h: the cell number and total cell insulin content were reduced by  $\sim 40\%$  while GSIS was blunted. There was a strong correlation between the generation of 4-HNE and these cytotoxic interactions. Interestingly, no such detrimental effects of PA were observed in cells maintained 5 mM glucose, in which 4-HNE level was moderate. Finally, a careful examination of the lipidomic analysis data showed additional glucose- and PA-induced changes in the content of various  $\omega$ -3- and  $\omega$ -6-PUFA, MUFA and SFA.

**Conclusion:** This study highlights the crucial role of glucose- and fatty acids-induced phospholipid remodeling in regulating  $\beta$ -cell function and in promoting cytotoxicity. It examined the impact of the liberation of AA and LA from phospholipids into the cell interior and the generation of the potent cytotoxic agent 4-HNE. Our current findings accentuate the need for thorough investigations of the mechanism of phospholipid remodeling, the subsequent generation of myriad lipid mediators and their impact on  $\beta$ -cell functions and dysfunction.

### Phenotypic characterisation of diabetic INS<sup>C94Y</sup> transgenic pigs

S. Renner<sup>1</sup>, C. Braun<sup>1</sup>, A. Blutke<sup>2</sup>, N. Herbach<sup>2</sup>, A. Wünsch<sup>1</sup>, M. Kurome<sup>1</sup>, B. Kessler<sup>1</sup>, S. Krebs<sup>3</sup>, O. Puk<sup>4</sup>, H. Nagashima<sup>5</sup>, J. Graw<sup>4</sup>, H. Blum<sup>3</sup>, R. Wanke<sup>2</sup>, E. Wolf<sup>1</sup>;

<sup>1</sup>Ludwig-Maximilians Universität München, Oberschleißheim, Germany,

<sup>2</sup>Ludwig-Maximilians Universität München, Institute of Veterinary Pathology, Munich, Germany, <sup>3</sup>Gene Center of the Ludwig Maximilians Universität München, Munich, Germany, <sup>4</sup>Helmholtz Center Munich-German Research Center for Environmental Health, Institute of Developmental Genetics, Neuherberg, Germany, <sup>5</sup>Meiji University, Laboratory of Developmental Engineering, Kawasaki, Japan.

**Background and aims:** Islet (xeno-)transplantation as well as preclinical testing of novel therapeutic strategies require diabetic large animal models showing close physiological and anatomical similarities to humans, *e.g.* pigs. To date, diabetes in the pig can be induced either by pancreatectomy or chemical agents, *e.g.* streptozotocin. Due to substantial drawbacks of these existing models, our aim was to generate a transgenic diabetic pig model, expressing a mutant porcine insulin gene (INS<sup>C94Y</sup>) resembling the human and murine INS<sup>C96Y</sup> mutation which leads to permanent neonatal diabetes.

**Materials and methods:** INS<sup>C94Y</sup> transgenic (tg) pigs were generated by somatic cell nuclear transfer using porcine fetal fibroblasts stably transfected with a porcine INS<sup>C94Y</sup> expression vector (provided by Dr. H. Flawinkel). The ratio of INS<sup>C94Y</sup> and INS transcripts in pancreatic tissue was determined by next generation sequencing technology. The total  $\beta$ -cell volume was determined by quantitative-stereological analyses.

**Results:** In total, 7 INS<sup>C94Y</sup> tg founder boars were born. One founder showed elevated fasting blood glucose levels at the age of 85 days, further increasing

over time. The ratio of *INS*<sup>C94Y</sup> to *INS* transcripts (0.751) in pancreas of the diabetic founder was at least 5-fold higher than in the 6 non-diabetic founders. Under insulin treatment, the diabetic boar developed nearly normal and was successfully mated to non-transgenic sows. The transgene was inherited to 50% of the offspring according to mendelian rules. The *INS*<sup>C94Y</sup> to *INS* transcript ratio in pancreas of F1-offspring was similar to the founder boar (0.775 ± 0.05; n = 3). Transgenic F1-/F2-offspring exhibited significantly elevated random blood glucose levels within 24 hours after birth vs. controls (194 ± 12 vs. 146 ± 9 mg/dl; p=0.03). Fasting insulin levels were unaltered in 8-day-old *INS*<sup>C94Y</sup> tg pigs, but were significantly reduced at the age of 4.5 months vs. controls (2.0 ± 0.42 vs. 5.1 ± 0.77 µU/ml; p<0.01). Also, 4.5-month-old *INS*<sup>C94Y</sup> tg pigs revealed a significantly elevated HOMA-IR index (2.4 ± 0.48 vs. 1.2 ± 0.24; p<0.05) indicating insulin resistance. Despite the early onset of hyperglycemia, total β-cell volume of 8-day-old tg pigs was not different compared to controls (136 ± 37 vs. 137 ± 15 mm<sup>3</sup>; p=0.68). In contrast, 4.5-month-old *INS*<sup>C94Y</sup> tg pigs revealed a 77% reduced total β-cell volume related to BW (4 ± 0.45 vs. 17.2 ± 2.4 mm<sup>3</sup>/kg; p<0.0001). Electron microscopy of β-cells from 4.5-month-old *INS*<sup>C94Y</sup> tg pigs showed a very low number of insulin secretory granules and severe dilation of the endoplasmic reticulum (ER) while in 8-day-old tg piglets insulin granules were present and the ER-dilation less severe.

**Conclusion:** *INS*<sup>C94Y</sup> tg pigs exhibit a stable diabetic phenotype and survive under insulin treatment and are therefore a valuable animal model for numerous applications. The evaluation for the development of diabetic complications is currently ongoing.

**Reduction in pancreatic beta cell mass caused by enhanced expression of *Cdkn1c* as a result of interaction between C/EBPβ and epigenetic control**  
K. Teruyama<sup>1</sup>, S.-I. Asahara<sup>2</sup>, H. Inoue<sup>1</sup>, H. Etoh<sup>1</sup>, T. Matsuda<sup>2</sup>, S. Seino<sup>2</sup>, Y. Kido<sup>1,2</sup>

<sup>1</sup>Kobe University Graduate School of Health Sciences, <sup>2</sup>Kobe University Graduate School of Medicine, Kobe, Japan.

**Background and aims:** The relationship between pancreatic β-cell mass and the onset and progression of type 2 diabetes mellitus has received a lot of attention in recent years. Our research focused on the *Cdkn1c* gene, which codes for a cell cycle inhibitor, because it is involved in the regulation of pancreatic β-cell mass. The *Cdkn1c* gene is an imprinting gene whose expression is controlled by the non-coding RNA Kcnq1ot1. We found that when the expression of Kcnq1ot1 decreased, epigenetic alterations induced an increase in the expression of *Cdkn1c*, which, in turn, led to a decrease in the pancreatic β-cell mass. We have already reported that the transcription factor C/EBPβ accumulates in the pancreatic β-cells of high fat-fed mice. It has been reported that a binding motif of C/EBPβ is present in the *Cdkn1c* promoter. On the basis of these findings, we hypothesize that the accumulation of C/EBPβ in pancreatic β-cells with reduced expression of Kcnq1ot1 causes further enhancement of *Cdkn1c* expression and promotes pancreatic β-cell failure.

**Materials and methods:** C/EBPβ was overexpressed in MIN6 cells treated with an inhibitor of epigenetic modification. In addition, Kcnq1ot1-truncated C/EBPβ-overexpressing mice (*KT* mice) were produced by cross-breeding Kcnq1ot1-truncated mice with pancreatic β cell-specific C/EBPβ-overexpressing mice.

**Results:** The findings showed that the expression of *Cdkn1c* in MIN6 cells was not influenced by the expression level of C/EBPβ, however, it was enhanced by treatment with an inhibitor of epigenetic modification, and was further enhanced by C/EBPβ overexpression. Studies using chromatin immunoprecipitation (ChIP) assays have shown that the binding between C/EBPβ and the *Cdkn1c* promoter was significantly enhanced during treatment with the inhibitor than under normal conditions. *In vivo* studies have shown that compared to C/EBPβ-overexpressing mice and wild-type mice, *KT* mice show significantly higher blood glucose levels, smaller pancreatic β-cell mass, and enhanced expression of *Cdkn1c* in the pancreatic islets.

**Conclusion:** The findings suggest that the introduction of epigenetic modifications into MIN6 cells or pancreatic β-cells may lead to enhanced binding of C/EBPβ to the *Cdkn1c* promoter, then an increase in the expression levels of *Cdkn1c*, and a decrease in pancreatic β-cell mass.

## 507

**Human Krüppel-like factor 11 differentially regulates human insulin promoter activity in beta cells and non-beta cells via p300, PDX1 and the A3 element**

N. Perakakis<sup>1</sup>, D. Danassi<sup>1</sup>, M. Alt<sup>1</sup>, E. Tsaroucha<sup>1</sup>, A.E. Mehana<sup>1,2</sup>, N. Rimmer<sup>1</sup>, K. Laubner<sup>1</sup>, H. Wang<sup>3</sup>, C.B. Wollheim<sup>4</sup>, J. Seufert<sup>1</sup>, G. Paeth<sup>1</sup>; <sup>1</sup>Endocrinology and Diabetology, Internal Medicine II, University Hospital of Freiburg, Germany, <sup>2</sup>Institute of Biology II, University of Freiburg, Germany, <sup>3</sup>F. Hoffmann-La Roche AG, Metabolic and Vascular Diseases, Basel, Switzerland, <sup>4</sup>Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

**Objective:** Human Krüppel-like factor 11 (hKLF11) belongs to the Sp1/KLF transcription factor family and has been identified as the MODY7 gene. The molecular functions of hKLF11 in pancreatic beta cells, however, are not well characterised, as it has been reported to both activate and inhibit human proinsulin gene promoter (hInsP) activity. Since hKLF11 can differentially regulate MAO B gene activity depending on recruited cofactors, we investigated possible interactions between hKLF11 and important beta cell transcription factors focusing on the role of the p300/PDX1 transactivation complex. In order to differentiate between endogenous beta cell specific and non-specific effects, we performed our experiments both in beta cells and non-beta cells (HEK293).

**Results:** By mammalian two hybrid assay, we detected direct protein interactions between hKLF11 and p300 but not with PDX1. Cotransfection of hKLF11 and hInsP-driven secreted alkaline phosphatase reporter vectors (-881+54hInsP-SEAP) characterised hKLF11 as an inhibitor of hInsP activity in beta cells. In contrast, we observed strong hKLF11-mediated stimulation of hInsP in HEK293 cells, even in the presence of cotransfected beta-cell-specific PDX1. Both inhibition and stimulation depended on the activity of the coactivator p300, since additional coexpression of hp300 in INS-1E or of the p300 inhibitor E1A in HEK293 neutralised hKLF11 functions. Doxycycline induction of dominant negative (DN)-PDX1 in transgenic INSrβ beta cells fully blocked hKLF11 function on hInsP underscoring the importance of the PDX1-p300 transcriptional complex for hKLF11 function in beta cells. We further observed loss of hKLF11 functions both in beta cells and in HEK293 cells after 5'-deletion or internal block mutation of the important PDX1 binding element A3. Of note, deletion or mutation of the other PDX1 binding sites within hInsP (A5, GG2 and A1) had no effect.

**Conclusion:** These results characterise hKLF11 as an important regulator of hInsP activity via the p300/PDX1 transactivation complex and the A3 cis acting element. Disturbance of these molecular mechanisms may contribute to the development of MODY7 in monogenic hKLF11 gene mutations.

## 508

**Expression of the Alx3 homeodomain gene in pancreatic beta cells is regulated by USF1/USF2 and glucose**

A. Fernandez-Perez, M. Mirasierra, P. Garcia-Sanz, M. Vallejo; Ciber de Diabetes y Enfermedades Metabólicas Ciberdem, Instituto de Investigaciones Biomédicas Alberto Sols, Madrid, Spain.

**Background and aims:** Alx3 is an aristaless-type homeodomain transcription factor expressed in pancreatic islets. In previous studies we determined that Alx3 participates in the regulated expression of several islet genes, including insulin, glucagon, glucokinase and somatostatin. In addition, we demonstrated that lack of Alx3 in mice compromises islet cell survival leading to alterations in glucose homeostasis characterized by increased fasting blood glucose levels, impaired glucose tolerance, and age-dependent insulin resistance. Initial studies to investigate the mechanisms that regulate the expression of the Alx3 gene in pancreatic islets revealed the existence of multiple E-box promoter elements distributed over a region of approximately 2 kb of the promoter. In the present study, we sought to investigate the transcriptional mechanisms that regulate expression of Alx3 in pancreatic islets by identifying and analyzing functional promoter cis-DNA regulatory elements and the transcription factors that bind to them. In addition, we sought to determine whether expression of Alx3 in pancreatic islets is dependent on the concentration of glucose.

**Materials and methods:** Expression of Alx3 was assessed by quantitative RT-PCR. Luciferase reporter genes constructed with different regions of the mouse Alx3 promoter were transfected in islet- and non-islet-derived cell lines. PCR-based site directed mutagenesis of single or multiple promoter elements was used for functional studies of the promoter. Binding of nuclear

proteins to promoter elements was investigated by chromatin immunoprecipitation and electrophoretic mobility shift assays.

**Results:** Expression of Alx3 in MIN6 pancreatic beta cells was found to be proportionally dependent on the concentration of glucose. We identified 10 E-box type elements (named EB1–10) within a region of 2 kb of the Alx3 promoter. Mutation analyses followed by transfection in MIN6 indicated that at least four (EB1, EB4, EB8 and EB9/10) were found to be required for full transcriptional activity. Transcription factors USF1 and USF2 were found to bind preferentially to EB1 and EB8, respectively, by chromatin immunoprecipitation and electrophoretic mobility shift assays. In addition, both transcription factors were found to bind EB4 but not EB9/10. Transfections in insulin producing MIN6 cells using an expression vector encoding a dominant negative inhibitor of USF transcription factors indicated that they are required for full Alx3 promoter activity. We found that USF1 and 2 act synergistically, and that the integrity of at least EB1 and EB2 elements is required for these synergistic interactions. On EB1, USF1 appears to interact with the basal transcription machinery via direct contact with TFII-I. Finally, we found that Alx3 transcription is inducible by glucose, but this response is maintained in the presence of a dominant negative inhibitor of USF transcription factors.

**Conclusion:** Expression of Alx3 in pancreatic islet cells is regulated by the co-ordinated activity of USF1 and USF2 transcription factors binding concomitantly to at least three E-box promoter elements. USF transcription factors do not appear to be involved in glucose-regulated expression of Alx3.

### Increase of beta cell mass via paracrine GLP-1 by selective non-viral GLP-1 gene therapy into alpha cells in intact pancreatic islets

J. Park<sup>1</sup>, H.-S. Jung<sup>2</sup>, J.-S. Lee<sup>2</sup>, N. Han<sup>1</sup>, S. Kim<sup>1</sup>, E. Lee<sup>1</sup>, T. Kim<sup>1</sup>, T. Kim<sup>1</sup>, M. Kwon<sup>1</sup>, S. Lee<sup>1</sup>, M. Park<sup>3</sup>, B. Rhee<sup>1</sup>, M. Kim<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine, College of Medicine, Inje University,

<sup>2</sup>Paik Institute for Clinical Research, Inje University, <sup>3</sup>Department of Internal Medicine, College of Medicine, Dong-A University, Busan, Republic of Korea.

**Background and aims:** Glucagon-like peptide-1 (GLP-1) is an incretin hormone expecting improvements in beta-cell survival and increase in beta cell mass. To overcome the short half-life of GLP-1, several groups have explored GLP-1 gene therapy in pancreatic beta cells. But, we have known that alpha cells were increased and beta cells were decreased with progression of diabetes. Long term safety of viral gene therapy is still major concern and beta cell proliferative effect is not clear. We rationalized that it may be desirable to have local GLP-1 production within the islet without raising peripheral levels. Therefore, we try to induce transient high concentration of GLP-1 expression in pancreatic alpha cells by sonoporation and find out their effects on proliferation of adjacent pancreatic beta cells

**Materials and methods:** Alpha TC-1 & Beta TC-6 cell was co-cultured with D-MEM medium and islets were isolated from wistar rats and maintained with M199 medium. Co-cultured alpha/beta cells or islet applied the mixture of pGlu-GLP-1 with PBS and then performed sonoporation (frequency, 1.0 MHz; duty, 20 %; intensity, 2.0 W/cm<sup>2</sup>; time, 30 s) at plate bottom using Sonitron 2000 ultrasonicator with a probe of diameter 6 mm. After 24hr or 48hr transfection, cells or islets were stained with ki-67 to confirm beta-cell proliferation change.

**Results:** Expression of GLP-1 mRNA and protein were detected in transfected alpha-TC-1 cell. Colocalization of GLP-1 and glucagon immunoreactivity was shown within the alpha-cells of islets. The levels of GLP-1 secreted from a-TC cells were over 10nmol. In co-culture with alpha and beta- cells, beta-TC-6 cell mass was increased. Ki-67 in beta cell of islet was significantly increased with transfected alpha cells.

**Conclusion:** Alpha cell targeted GLP-1 gene therapy by sonoporation led to localized GLP-1 expression in alpha cells and proliferation of beta cells. It will be another strategy to overcome.

## 510

### The role of Rb and its family protein p107 in regulating cell cycle of pancreatic beta and alpha cells

E.P. Cai<sup>1,2</sup>, X. Wu<sup>3</sup>, S.A. Schroer<sup>2</sup>, E. Zacksenhaus<sup>2</sup>, M. Woo<sup>2,4</sup>;

<sup>1</sup>Institute of Medical Science, University of Toronto, Canada, <sup>2</sup>Toronto

General Research Institute, University of Toronto, Canada, <sup>3</sup>The First

Affiliated Hospital, Nanjing Medical University, China, <sup>4</sup>Department of Medicine, St. Michael's Hospital, Toronto, Canada.

**Background and aims:** Insulin insufficiency and glucagon excess are considered to be major contributors for diabetes development. Pancreatic  $\beta$ -cells can re-enter cell cycle to compensate for increased insulin demand. Moreover, insulin deficiency due to  $\beta$ -cell death can stimulate  $\alpha$ -cell expansion and hyperglucanemia, further contributing to hyperglycemia. Therefore, evaluation of cell cycle regulation in both  $\beta$ - and  $\alpha$ -cells is essential for better understanding diabetes pathogenesis. Retinoblastoma protein (Rb) and its related protein, p107, play a critical role in cell cycle arrest and tissue differentiation but appear to be dispensable for post-mitotic cells. Rb plays a minor role in well-differentiated  $\beta$ -cells as shown in rat insulin promoter-driven Rb knockout islets. However, the effects of Rb in proliferating  $\beta$ - and  $\alpha$ -cells remain elusive.

**Materials and methods:** To investigate the role of Rb in proliferating  $\beta$ - and  $\alpha$ -cells, we have deleted Rb via Pdx1-Cre, and Pdx1-Cre:Rb<sup>fl/fl</sup> will be referred herein as RbKO mice. To assess the role of its family member p107, we used whole-body p107 knockout mice (p107KO), and Rb/p107 double knockout (DKO) mice were generated to assess the combined roles of these Rb family members in proliferating pancreatic  $\beta$ - and  $\alpha$ -cells.

**Results:** RbKO mice demonstrated improved glucose tolerance ( $p < 0.05$ ) without changes in insulin sensitivity, while p107KO had similar glucose tolerance compared to their littermate wildtype (WT) controls. Pancreatic sections of RbKO mice demonstrated increased  $\beta$ -cell area (+35%,  $p < 0.05$ ) and their islets exhibited enhanced  $\beta$ -cell function as assessed by in vivo glucose-stimulated insulin secretion ( $p < 0.05$ ) and increased protein levels of p-IRS1/2 (2.1-fold,  $p < 0.01$ ), p-Akt (2.0-fold,  $p < 0.01$ ), Pdx1 (2.9-fold,  $p < 0.001$ ), CyclinD1 (1.6-fold,  $p < 0.01$ ) and E2F1 (1.7-fold,  $p < 0.001$ ) but decreased p53 (0.7-fold,  $p < 0.01$ ), p27 (0.6-fold,  $p < 0.001$ ) and p21 (0.7-fold,  $p < 0.01$ ) levels. DKO mice showed improved glucose tolerance ( $p < 0.01$ ); however, this was abolished with aging. Both RbKO and DKO mice showed increased  $\beta$ -cell proliferation as assessed by Ki67 staining at 8 wks (2.2-fold,  $p < 0.05$ ; 1.7-fold,  $p < 0.05$ ). However, with aging, there was also a concomitant increase in  $\beta$ -cell apoptosis in DKO mice (2.5-fold,  $p < 0.05$ ), resulting in a net loss of  $\beta$ -cell mass in older (18–22 wks) DKO mice. Interestingly, RbKO and DKO mice demonstrated reduced glucagon levels compared to WT controls (74.1 $\pm$ 4.6 pg/ml in WT, 40.8 $\pm$ 3.3 pg/ml in RbKO, 46.1 $\pm$ 5.4 pg/ml in DKO;  $p < 0.001$ ) and  $\alpha$ -cell area (-60%,  $p < 0.001$ ; -93%,  $p < 0.001$ ), and reduced  $\alpha$ -cell developmental gene expressions, *arx* (-80%,  $p < 0.01$ ; -93%,  $p < 0.01$ ) and *pax6* (-63%,  $p < 0.001$ ; -66%,  $p < 0.001$ ).

**Conclusion:** These data reveal that Rb may display a dichotomous role in  $\beta$ - and  $\alpha$ -cells, whereby Rb loss leads to an increase in  $\beta$ -cell mass and a concomitant decrease in  $\alpha$ -cells. Additionally, combined loss of Rb and p107 leads to an age-dependent depletion of  $\beta$ -cells by apoptosis. Further understanding of the complexity in regulation of cell cycle, viability and differentiation of  $\beta$ - and  $\alpha$ -cells will provide new strategies for treatment of diabetes.

### RNA-sequencing identifies dysregulation of the human pancreatic islet transcriptome by the saturated fatty acid palmitate

M. Cnop<sup>1</sup>, G. Bottu<sup>1</sup>, T. Griebel<sup>2</sup>, B. Abdulkarim<sup>1</sup>, L. Marselli<sup>3</sup>, P. Marchetti<sup>3</sup>, M.I. McCarthy<sup>4</sup>, M. Sammeth<sup>2</sup>, D.L. Eizirik<sup>1</sup>;

<sup>1</sup>Laboratory of Experimental Medicine, Université Libre de Bruxelles, Brussels, Belgium, <sup>2</sup>Functional Bioinformatics, Centre Nacional d'Anàlisi Genòmica, Barcelona, Spain, <sup>3</sup>Department of Endocrinology and Metabolism, University of Pisa, Italy, <sup>4</sup>Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, UK.

**Background and aims:** Pancreatic beta cell dysfunction and death are central in the pathogenesis of type 2 diabetes but the underlying mechanisms are not fully understood. Saturated free fatty acids may cause beta cell failure and contribute to diabetes development in genetically predisposed individuals.

**Materials and methods:** RNA-sequencing was used to identify transcripts expressed in five human islet preparations, basally or following a 48-hour exposure to the saturated fatty acid palmitate (0.5 mM in the presence of 1% albumin). Organ donors were aged 55±9 years. Beta cell purity of the islets assessed by insulin immunostaining was 50±5%. Samples were sequenced on Illumina Genome Analyzer II and data analyzed using GEM mapper and Flux Capacitor software. Transcript expression was considered changed by Benjamini-Hochberg-corrected Fisher testing and if it changed significantly in ≥4/5 samples and in the opposite direction in none. Genes were annotated manually or using Ingenuity Pathway Analysis or DAVID.

**Results:** A total of 30,026 transcripts corresponding to 19,882 genes were expressed in the human islets. Palmitate induced 428 genes and downregulated 897 genes ( $p < 0.05$ ). These included genes regulating the endoplasmic reticulum stress response, ubiquitin and proteasome function, autophagy and apoptosis. Transcripts related to innate immunity were upregulated and several HLA transcripts were downregulated. Potassium channels and transcription factors controlling beta cell phenotype were inhibited by palmitate. Confirmation and functional studies of key genes are ongoing. 52/63 of the candidate genes for type 2 diabetes were expressed in human islets with an RPKM >1, and palmitate modified expression of 11 of these. Palmitate caused a shift in alternative splicing in 574 transcripts in human islets. Ingenuity Pathway Analysis of modified transcripts and genes confirmed that top changed functions related to cell death and cellular development. DAVID analysis of transcription binding sites in palmitate-modified transcripts revealed a role for the endoplasmic reticulum stress response regulators XBP-1 and ATF6, among others.

**Conclusion:** Using RNA-sequencing we mapped the human islet transcriptome and identified novel mechanisms of palmitate-induced beta cell dysfunction and death. These data also point to crosstalk between metabolic stress and several type 2 diabetes candidate genes at the beta cell level.

### FABP5 depletion protects from STZ induced diabetes

K. Zien<sup>1</sup>, J. Bergemann<sup>1</sup>, A. Meyer<sup>1</sup>, Y. Owada<sup>2</sup>, K. Maedler<sup>1</sup>;

<sup>1</sup>Centre for Biomolecular Interactions, University of Bremen, Germany,

<sup>2</sup>Department of Organ Anatomy, Minamikogushi, Japan.

**Background and aims:** Fatty acid binding proteins (FABPs) facilitate the uptake, transport and metabolism of fatty acids within the aquatic environment of the cell. FABP5 (E-FABP, mal1) polymorphisms are reported to be associated with type 2 diabetes in humans and a depletion of FABP5 in mice results in a protection from insulin resistance and diabetes upon high fat diet. FABP5 is expressed in rat islets and in the  $\beta$ -cell line INS1E of rat origin. Subsequently, we asked the question if FABP5 is also expressed in human and mouse islets and whether it regulates  $\beta$ -cell survival and function.

**Materials and methods:** FABP5<sup>-/-</sup> and wildtype mice were injected with a single dose streptozotocin (STZ, 100 mg/kg body weight) followed by an 8-week feeding of high fat/ high sucrose diet (HFD). Intraperitoneal glucose tolerance (IpGTT) and insulin tolerance tests (IpITT) were performed before and after STZ as well as during the diet.  $\beta$ -cell mass was analyzed by microscopical scanning of the tissue,  $\beta$ -cell survival and proliferation was monitored using double-staining for TUNEL or Ki67 and insulin. Isolated islets of wildtype and FABP5<sup>-/-</sup> mice were treated with a combination of glucose

(22.2mM) and palmitate (500 $\mu$ M) for three days and  $\beta$ -cell survival and function were monitored.

**Results:** FABP5 was expressed in human and mouse islets. STZ treatment of wildtype mice resulted in an 2.5-fold increase in fed blood glucose within two weeks while blood glucose increased only to 1.6-fold in FABP5<sup>-/-</sup> mice. WT mice injected with STZ showed impaired glucose tolerance after 2 weeks while this was partially prevented in FABP5<sup>-/-</sup> mice. After 8 weeks on HFD, STZ treated wildtype mice were completely glucose intolerant, while FABP5<sup>-/-</sup> mice showed a glucose tolerance similar to non-STZ-treated wildtype and FABP5<sup>-/-</sup> controls. The  $\beta$ -cell mass of wildtype mice was 50% reduced upon STZ-HFD treatment, while FABP5<sup>-/-</sup> mice had a 1.6-fold increased  $\beta$ -cell mass at all conditions, compared to wildtype mice. To further investigate lipotoxic effects on islets, we exposed isolated islets from FABP5<sup>-/-</sup> and wildtype mice to a pro-diabetic milieu. While the combination of glucose and palmitate induced apoptosis by 4-fold, islets from FABP5<sup>-/-</sup> mice were not affected. No change in proliferation could be observed.

**Conclusion:** Our data show, that the depletion of FABP5 improves  $\beta$ -cell function, survival and mass.

**Background and aims:** The p66Shc protein, through its phosphorylation on Ser36, regulates oxidative stress and cell survival in multiple cell types. Saturated FFA, if chronically in excess, can reduce insulin biosynthesis and secretion and induce beta-cell apoptosis, a phenomenon that has been termed “lipotoxicity”. In this study, the role of p66Shc in the FFA-dependent beta-cell apoptosis was explored.

**Materials and methods:** Expression and phosphorylation levels of specific signaling molecules were assessed by immunoblotting techniques. Gene expression was evaluated by real-time RT-PCR. Beta-cell apoptosis was quantified by an ELISA assay evaluating oligosome release into the cytosol and by detection of cleaved caspase-3 protein levels. Wild-type p66Shc and mutant p66Shc, in which Ser36 was replaced by Ala (p66Shc-Ala36), were selectively overexpressed by infecting cells with recombinant adenoviruses. Silencing of p66Shc was obtained following beta-cell transfection with two independent siRNAs.

**Results:** Exposure of rat INS-1E insulinoma cells and both human and mouse islets to 0.5 mM palmitate induced a selective 2- to 3-fold increase in both mRNA and protein levels of p66Shc ( $p<0.05$ ), respectively, without affecting the other Shc protein isoforms; furthermore, palmitate enhanced p66Shc phosphorylation on Ser36 ( $p<0.05$ ). When INS-1E cells were pre-treated with pifithrin- $\alpha$ , an inhibitor of the p53 protein, the palmitate-induced increase in p66Shc expression was completely abrogated ( $p<0.05$ ). Adenovirus-mediated overexpression of p66Shc resulted in increased phosphorylation of p66Shc on Ser36 and beta-cell apoptosis compared to control, both under basal conditions and following exposure to palmitate ( $p<0.05$ ). By contrast, overexpression of a phosphorylation-defective p66Shc protein, with Ser36 mutation to Ala, did not affect basal and reduced palmitate-induced apoptosis ( $p<0.05$ ). In addition, palmitate increased JNK phosphorylation, and cells with p66Shc overexpression showed increased basal and palmitate-induced JNK phosphorylation compared with control cells ( $p<0.05$ ). Inhibition of JNK phosphorylation by SP600125 prevented basal and palmitate-induced phosphorylation of p66Shc on Ser36 and beta-cell apoptosis ( $p<0.05$ ). Moreover, when the palmitate-dependent increase of p66Shc was inhibited using pifithrin- $\alpha$  or a specific p66Shc siRNA, palmitate-induced apoptosis was abrogated ( $p<0.05$ ). Finally, in pancreatic islets from cadaveric donors, p66Shc mRNA levels were found to be increased in obese/overweight (BMI>25) compared with lean (BMI<25) subjects ( $p<0.05$ ).

**Conclusion:** In pancreatic beta-cells the FFA palmitate triggers the p53-mediated upregulation of the p66Shc protein, which is phosphorylated on Ser36 by JNK, and mediates a pro-apoptotic response. Thus, p66Shc acts as a novel signaling intermediate in the FFA-mediated beta-cell damage, and is up-regulated in human obesity. p66Shc may thus represent a potential novel target to prevent the deleterious effects of lipotoxicity on pancreatic beta-cells.

### Unsaturated fatty acids protect against reactive oxygen species mediated lipotoxicity in insulin-producing cells

M. Elsner<sup>1</sup>, W. Gehrmann<sup>1</sup>, A. Jörns<sup>1,2</sup>, S. Lenzen<sup>1</sup>;

<sup>1</sup>Institute of Clinical Biochemistry, <sup>2</sup>Centre of Anatomy, Hannover Medical School, Germany.

**Background and aims:** Elevated levels of non-esterified fatty acids (NEFAs) can cause beta cell dysfunction and apoptosis in T2DM. Palmitic acid, the physiologically most abundant saturated NEFA, has a strong cytotoxic effect upon insulin-producing cells, whereas unsaturated NEFAs are not toxic and can even protect against the toxicity of long chain saturated NEFA induced lipotoxicity. Long chain NEFAs can be metabolized not only in the mitochondria but also in the peroxisomes. In contrast to mitochondrial  $\beta$ -oxidation, the acyl-CoA oxidases in the peroxisomes generate hydrogen peroxide

( $H_2O_2$ ) and not reducing equivalents. Since  $\beta$ -cells lack almost completely catalase expression they are exceptionally vulnerable by  $H_2O_2$ . It was the aim of the present study to analyse the structural requirement of unsaturated NEFAs for the protection against saturated NEFA mediated toxicity in insulin producing cells and to investigate the mechanism of protection.

**Materials and methods:** Cell viability of insulin-producing RINm5F cells was determined by MTT assay after 24 h exposure to palmitic acid (PA) and different unsaturated NEFAs. The induction of apoptosis was analysed by caspase-3 assay. DCF was used to quantify reactive oxygen species formation in RINm5F cells overexpressing catalase after exposure to PA and oleic acid (OA). For specific cellular analysis of hydrogen peroxide generation after incubation with PA and OA the  $H_2O_2$  sensitive protein HyPer was overexpressed in the peroxisomes of RINm5F cells and primary rat beta cells. Ultrastructural changes in the morphology of RINm5F cells caused by NEFAs were analysed by electron microscopy.

**Results:** The toxicity of saturated NEFAs and the protective effect of unsaturated NEFAs decreased with shortening of the chain length. The  $EC_{50}$  value for palmitic acid (C16:0) was around 100  $\mu$ M. While oleic (C18:1), linoleic (18:2), gamma linoleic acid (18:3) and palmitoleic acid (C16:1) had a similar strong protective effect, myristoleic acid (C14:1) and dodecenoic acid (C12:1) were less effective against PA induced toxicity. The induction of caspase-3 by PA was inhibited through incubation with OA. Only overexpression of catalase in the peroxisome or a co-incubation with OA reduced PA induced ROS generation to the same level of untreated control cells. In primary rat beta cells overexpressing the hydrogen peroxide sensor protein HyPer the  $H_2O_2$  production increased 10fold after PA incubation in comparison to untreated cells while OA treatment results not in a significant increase in  $H_2O_2$  production. Moreover OA was able to prevent the PA mediated induction of hydrogen peroxide production. The EM analyses revealed after incubation with PA clear damage of the rough ER, while the mitochondria remained intact. The cisternae of the ER were elongated and dilated containing dark deposits. When the cells were incubated with OA lipid droplets accumulated in the cytoplasm, whereas the ER remained unaffected. Minor accumulation of lipid droplets and damage to the ER were observed when the cells were treated with a mixture of PA and OA.

**Conclusion:** The protective effect of unsaturated NEFA against lipotoxicity was chain-length dependent but independent on the number of double bonds. OA was able to prevent PA induced  $H_2O_2$  production in insulin producing RINm5F cells and primary rat beta cells. Our findings indicate that ROS play an important role for lipotoxicity.

### Evidence of reduced ER-to-Golgi trafficking of endogenous cargo protein in lipotoxic beta cells and islets of db/db mice

N. Sue, J.Y. Chan, D.R. Laybutt, T.J. Biden;

Diabetes and Obesity Program, Garvan Institute of Medical Research, Darlinghurst, Australia.

**Background and aims:** Saturated fatty acids lead to a trafficking defect in pancreatic beta cells, which contributes to ER stress via protein overload. A VSVG reporter protein has been used previously to demonstrate delayed ER-to-Golgi trafficking in the presence of palmitate. Our aim was to confirm this defect for endogenous cargo in the beta cell, and to extend the characterisation further by investigating whether there was a selectivity of this trafficking delay for particular cargo proteins, or if it was a generalised phenomenon. We also wanted to explore this ER-to-Golgi trafficking defect in the context of an animal model of diabetes. To this end, we monitored changes in the expression level of a number of ER-Golgi secretory pathway related genes in islets of *db/db* mice as they progressed from a pre-diabetic to diabetic state.

**Materials and methods:** Vesicle budding assays were used to reconstitute the process of ER-to-Golgi trafficking in a cell free system. In this assay, bulk cytosol extracted from mouse liver was incubated at 37°C with a microsomal (chiefly ER) fraction isolated from MIN6  $\beta$ -cells pre-treated for 48 hours with palmitate (0.4 mmol/l Palm: 0.92% BSA) or control BSA. Secretory vesicles bud off from the ER membranes, and are separated from membranes by differential centrifugation. The incorporation of endogenous cargo proteins into the budded off vesicles was monitored by immunoblotting. Islets were isolated from *db/db* and control mice at 6 (pre-diabetic) and 16 (diabetic) weeks of age. Gene expression of a number of secretory pathway genes was assessed by quantitative PCR.

**Results:** Vesicle budding assays revealed that there was a time-dependent increase in vesicular trafficking of the endogenous cargo protein Carboxypeptidase E (CPE). This budding was diminished in microsomes from palmitate pre-treated MIN6 cells (fold enrichment in vesicles: Control  $4.48 \pm 2.3$ ; palmitate  $2.48 \pm 0.3$ ;  $n=2$ ), even after allowing for the reduced CPE protein levels in response to palmitate treatment. We also studied *db/db* mice which are a model of beta cell dysfunction and type 2 diabetes. In their islets, the expression of a variety of secretory pathway genes was down-regulated in the progression to the diabetic state. These include significant reductions in Sec24a (52%), Sec24d (35%), Lman1 (53%), Rpn1 (40%), and Ssr3 (31%) ( $p<0.05$  *db/db* 6 week vs *db/db* 16 week by t-test,  $n=8-12$ ). Conversely, the expression levels of these genes did not change in the control mice over the same period. These reductions are consistent with a down-regulation of ER-to-Golgi trafficking.

**Conclusion:** We have employed two independent approaches to provide support to the concept that protein trafficking through the early secretory pathway in pancreatic beta cells is adversely affected by lipid oversupply and in the context of diabetes.

### HDLs use multiple pathways to protect pancreatic beta cells against ER stressors

C. Widmann<sup>1</sup>, J. Puyal<sup>2</sup>, G. Dubuis<sup>1</sup>, J. Pétremand<sup>1</sup>;

<sup>1</sup>Physiology, <sup>2</sup>Cell Biology and Morphology, University of Lausanne, Switzerland.

**Background and aims:** HDLs protect pancreatic beta cells against apoptosis induced by several ER stressors, including thapsigargin, cyclopiazonic acid, palmitate and insulin over-expression. This protection is mediated by the capacity of HDLs to maintain proper ER morphology and ER functions such as protein folding and trafficking. Here we investigated whether HDLs used a similar pathway to protect beta cells against tunicamycin (TM), a protein glycosylation inhibitor inducing ER stress.

**Materials and methods:** The Min6 insulinoma cell line was incubated with TM in the presence or in the absence of HDLs. The extent of apoptosis was determined by scoring the number of cells displaying pyknotic nucleus. ER stress was assessed by measuring the induction of various stress markers (XBP1 splicing, CHOP and BiP induction, PERK activation, etc). Protein folding and trafficking from the ER to the Golgi was investigated using a temperature-sensitive mutant of a vesicular stomatitis virus glycoprotein (VSVG) fused to GFP whose folding and trafficking can be monitored. ER morphology was assessed by electron microscopy.

**Results:** HDLs inhibited apoptosis induced by tunicamycin in Min6 cells. Surprisingly, this protection was neither associated with a reduction in ER stress nor with restoration of protein folding and trafficking in the ER.

**Conclusion:** These data indicate that HDLs can use at least two mechanisms to protect beta cells against ER stressors. One that relies on the maintenance of ER function and one that operates independently of ER function modulation. The capacity of HDLs to activate several anti-apoptotic pathways in beta cells may explain their ability to efficiently protect these cells against a variety of insults.

## 517

### Subtle alterations in sphingolipid and cholesterol content within the endoplasmic reticulum (ER) of pancreatic beta cells underlies ER dysfunction, stress and lipoapoptosis

E. Boslem<sup>1</sup>, G. MacIntosh<sup>2</sup>, P.J. Meikle<sup>2</sup>, T.J. Biden<sup>1</sup>;

<sup>1</sup>Diabetes and Obesity, Garvan Institute of Medical Research, Sydney, <sup>2</sup>Baker IDI Heart and Diabetes Institute, Melbourne, Australia.

**Background and aims:** Fatty acid (FA) oversupply contributes to the  $\beta$ -cell death that occurs in type 2 diabetes. This death is mediated in part by chronic, unresolved endoplasmic reticulum (ER) stress signalling and is specific to saturated FA exposure. Since we have previously implicated sphingolipid metabolism and defective protein trafficking in this process, our current aim was to identify the exact metabolite and mechanism of action underlying this cytotoxicity.

**Materials and methods:** MIN6 cells, were treated chronically (48 h) with 0.4mM palmitate (palm):0.92% BSA, as a mild model of lipid oversupply. The level of apoptosis (DNA fragmentation ELISA) was determined fol-

lowing palm treatment and in combination with genetic intervention via overexpression (oe). Other endpoint analyses included lipidomics via mass spectrometry, western blotting of ER stress proteins and measurement of cholesterol regulated genes via a luciferase tagged sterol regulatory element (SRE) reporter.

**Results:** Palm treatment caused an overall decrease in ER sphingomyelin (SM) content (-38%,  $p=0.06$ ) as well as a localized increase in ER ceramide (Cer) content (56%,  $p=0.04$ ). Consistent with this was a 0.67 fold decrease ( $p=0.06$ ) in mRNA expression levels of ceramide transport protein (CERT) responsible for ER-to-golgi transport of Cer. Unsaturated FA oleate, did not suppress transcription of CERT and augmented its activation. Inhibiting CERT function was also sufficient to augment ER stress in the presence of palm (2 fold). However, oe of wild type or a constitutively active CERT mutant did not protect from lipoapoptosis or ER stress, which argued against ER Cer as playing a causative role in either defect. The inability of glucosylceramide synthase (GCS) oe to prevent ER Cer accrual, a strategy previously shown to protect from lipoapoptosis, ER stress and the palm-induced vesicular traffic delay, agreed with this conclusion. The palm-induced decrease in ER SM content was hence investigated, and a concomitant decrease in free cholesterol (FC) at the ER (-28%) and plasma membrane (-20%) was found, which stimulated SRE-driven gene expression (2.2 fold). These reductions were reversed by GC synthase (GCS) oe. Reciprocal modulations of apoptosis occur when the proportion of Cer to SM is altered via SM synthase 1 oe (-25%) or neutral ER SMase oe (20%) consistent with a regulatory role for ER SM content. SM and FC are associated in lipid rafts therefore perturbations of these ER microdomains may disturb  $\beta$ -cell subcellular membrane function. This might also explain alterations in downstream proinsulin to insulin conversion (proinsulin/insulin -43% with palm, +170% palm+SMS1 oe).

**Conclusion:** Subtle alterations in SM and FC content of the ER potentially underlie this organelle's dysfunction that leads to ER stress and lipoapoptosis. This may impact on vesicle membrane dynamic processes such as budding and golgi cisternal progression. This may be the source of the protein backlog previously hypothesised to cause the ER-to-golgi protein vesicular trafficking delay. Enhanced activation of CERT by oleate may be important for its cytoprotective action of unsaturated FAs.

### GRP78 overexpression in pancreatic beta cells protects from high fat diet-induced diabetes in mice

A. Volchuk<sup>1</sup>, T. Teodoro<sup>2</sup>, I. Schuiki<sup>1</sup>, L. Zhang<sup>1</sup>;

<sup>1</sup>Cellular & Molecular Biology, Toronto General Research Institute,

<sup>2</sup>Biochemistry, University of Toronto, Canada.

**Background and aims:** Endoplasmic reticulum (ER) stress is a potential mechanism involved in type 2 diabetes pathology and has been shown to contribute to both insulin resistance in liver and adipose tissue and pancreatic beta-cell dysfunction. We hypothesized that increased ER chaperone capacity would protect pancreatic beta-cells from dysfunction resulting from obesity and improve glucose homeostasis in mice on a chronic high fat diet (HFD).

**Materials and methods:** To examine whether ER stress in pancreatic beta-cells contributes to the development of type 2 diabetes we generated a mouse model that over-expresses the resident ER chaperone and unfolded protein response regulator GRP78/BiP in pancreatic beta-cells under the control of a rat insulin promoter. Transgenic and control mice were challenged with a HFD and metabolic parameters and ER stress markers in islets were analyzed.

**Results:** In transgenic C57B/6 mice expression of the RIP-GRP78myc transgene was restricted to pancreatic beta-cells in islets and was approximately 8-fold higher compared to transgene negative control mice. Transgenic mice had normal weight gain, metabolic physiology and islet architecture on a regular chow diet. Control mice on a 20-week HFD (45% kcal from fat) developed obesity, glucose intolerance, insulin resistance and islet hypertrophy. Remarkably, GRP78 transgenic mice tended to be leaner than their transgene negative littermates and were protected from glucose intolerance and insulin resistance. Furthermore, islets from transgenic mice had reduced hypertrophy and the mice were less hyperinsulinemic compared to controls on the HFD. In control animals HFD induced mild ER stress in islets, which correlated with reduced islet GLUT2 expression. Islets from transgenic mice were protected from ER stress and had increased cell surface GLUT2 expression compared to control mice on the HFD.

**Conclusion:** Overall, these data show that increased chaperone capacity in pancreatic beta-cells protects from ER stress and the pathogenesis of obesity-

induced type 2 diabetes. By maintaining pancreatic beta-cell function whole body glucose homeostasis is improved in transgenic mice on a HFD.

### A proteomic investigation of the response induced by palmitate and thapsigargin in the insulin producing cell line INS-1E

V. Rosengren<sup>1</sup>, H. Johansson<sup>2</sup>, J. Lehtiö<sup>2</sup>, Å. Sjöholm<sup>1</sup>, H. Orsäter<sup>1</sup>;

<sup>1</sup>Department of Clinical Science and Education, Södersjukhuset,

<sup>2</sup>Department of Oncology and Pathology, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Pancreatic beta-cells have a highly developed endoplasmic reticulum (ER) in order to meet the high demand for synthesis of insulin. Saturated fatty acids has been shown to induce the ER stress response in pancreatic beta-cells and this has been put forwarded as a mechanism for fatty acid toxicity in these cells. The aim of this study was to compare the cellular protein changes in INS-1E cells after exposure to the saturated fatty acid palmitate (Palm) and the ER stress inducer thapsigargin (Th), to investigate the regulation of proteins inside ER and the connection to other parts of the cell.

**Materials and methods:** INS-1E cells were treated with 0.4mM Palm or 200nM Th for 0, 4, 16 or 24 hours (h). After treatment cellular protein were isolated and subjected to iTRAQ labelling using 8 different isobaric tags for each data set. Analysis of the peptides was performed by LC/MS/MS. Identification was performed against the Uniprot database. ProteinCenter was used to categorize proteins according to GO annotations and Ingenuity Pathway Analysis (IPA) was used for investigation of canonical pathways and networks. Induction of apoptosis were investigated by measuring DNA fragmentation after treatment.

**Results:** Used concentrations of Th and Palm results in the same degree of apoptosis after 24 h of treatment. Proteomic analysis with iTRAQ offers a way to identify and quantify 8 samples in one assay. Two independent samples from each time point were combined in the analysis resulting in Two data sets. From the identification of 7073 unique proteins, 1% FDR, 5673 proteins were overlapping between the data sets and used for further analysis. Differentially expressed proteins were extracted and resulted in 1236 proteins after Th treatment and 272 proteins after Palm. Investigation of the regulated proteins in ProteinCenter reveals that 4 h of treatment with Th leads to over represented ER proteins while ribonucleoprotein complexes are under represented. At the time points 16 and 24 h ribonucleoprotein complexes are still under represented as well as the biological process RNA processing. Treatment with Palm for 16 h leads to over represented spindle proteins while the over represented biological processes are M-phase and lipid metabolic process. Investigation of regulated proteins in IPA reveals that networks involved in cell cycle and cell death were over represented after Th treatment. Palm showed over representation of networks involved in lipid metabolism, small molecule biochemistry and molecular transport. Pathways over represented after Th treatment were Biosynthesis of steroids, Polo-like kinases and protein ubiquitination pathway. Pathways over represented after Palm treatment were Polo-like kinases, fatty acid elongation in mitochondria and fatty acid biosynthesis.

**Conclusion:** The results from this study provides a large number of identified proteins, 5673 unique proteins positively identified in two independent data sets. Experiments with time series data can give valuable information about the dynamic regulation of proteins since activated processes can vary over time. Although both Palm and Thaps induced the same extent of apoptosis in these experiments the qualitative effects on the proteome was different. The treatment intervened with cellular RNA handling which was an effect not shared by Palm.

## 520

### Impaired islet expression of islet brain 1 in diabetes and in response to chronic palmitate exposure: role for proteasome and inducible cAMP early repressor

S. Brajkovic<sup>1</sup>, F. Wetter<sup>1</sup>, B. Lefebvre<sup>2</sup>, F. Pattou<sup>2</sup>, G. Waeber<sup>3</sup>, A. Abderrahmani<sup>4</sup>;

<sup>1</sup>Department of Cell Biology and Morphology, Lausanne, Switzerland,

<sup>2</sup>University of Lille Nord de France, Department of Endocrine Surgery-

Lille University Hospital, France, <sup>3</sup>Service of Internal Medicine, Lausanne, Switzerland, <sup>4</sup>University of Lille Nord de France, France.

**Background and aims:** The mitogen activated protein kinase 8 interacting protein 1 also called JNK interacting protein 1 or islet brain 1 (IB1) is candidate gene for T2D. IB1 maintains appropriate insulin expression and  $\beta$ -cells survival against pro-apoptotic stimuli. Decrease in the IB1 contents is thought to account for  $\beta$ -cells death evoked by most diabetogenic environment, and is deemed to contribute to the development of diabetes. Chronic exposure of islet  $\beta$ -cells to high concentrations of the saturated free fatty acid palmitate exerts adverse effects on  $\beta$ -cells tasks and cells survival. The aim of the study was to determine whether reduction of IB1 expression contributes to the deleterious effects of palmitate in beta cells.

**Material and methods:** Human islets were isolated from brain-dead organ donors with type 2 diabetes or not. Palmitate was coupled to bovine serum albumin in a molar ratio of 5:1. Human isolated islets, as well as mouse insulin secreting MIN6 cells were cultured with palmitate at different incubation times and concentrations. The protein and mRNA contents were analyzed by Western blotting experiments and quantitative real-time PCR, respectively.

**Results:** Prolonged incubation of insulin-producing cells to palmitate 0.5 mM decreased the IB1 protein contents at low and high glucose concentration. Loss of IB1 proteins appeared at 24 hours incubation. The ER stress inducers such as thapsigargin mimicked the effects of palmitate on the IB1 abundance. Reduction in the IB1 levels resulted from increased proteasome-mediated degradation but was independent of unfolded protein response. Chemical chaperones were unable to prevent reduction of IB1 caused by palmitate or thapsigargin, whereas proteasome inhibitors permitted a full restoration in the IB1 contents. Beside of the protein contents, chronic palmitate elicited a decrease in the IB1 mRNA levels. This diminution was observed in isolated human islets incubated with palmitate and in diabetic islets. Reduction of the IB1 transcripts caused by palmitate was associated with an increase in the inducible cAMP early repressor (ICER), a transcription factor known to repress IB1 in  $\beta$ -cells.

**Conclusion:** Palmitate reduces the levels of the cyto-protective IB1 by promoting protein degradation and by affecting transcriptional activity through ICER. This mechanism could account for islets dysfunction in diabetes.

### Amino acid toxicity in pancreatic beta cells, a potential new link between obesity and type 2 diabetes

N. Mullooly<sup>1</sup>, D. Smith<sup>2</sup>, P. Newsholme<sup>1,3</sup>;<sup>1</sup>University College Dublin, Co. Roscommon, Ireland, <sup>2</sup>Astrazeneca, Manchester, UK, <sup>3</sup>Curtin University, Perth, Australia.

**Background and aims:** Obesity and the metabolic syndrome are associated with excessive lipid and protein intake. Recent metabolic profiling studies have demonstrated strong correlations between branched-chain amino acid levels and type 2 diabetes susceptibility. Glucose and lipids in chronic excess have toxic effects on pancreatic beta cells but the effect of hyperaminoemia on beta cell function has never been investigated to date. The aim of this study was to investigate the effect of prolonged elevations in amino acid levels on beta cell function in vitro.

**Materials and methods:** Isolated rat islets were incubated over periods of 48 hours with increasing concentrations of individual amino acids (0.1 μM–10 mM). The amino acids selected for investigation were those with known insulin stimulatory effects (L-arginine, L-alanine, L-glutamine), and the branched chain amino acids (L-valine, L-leucine, L-isoleucine). After the chronic incubation period islets were assessed for beta cell proliferation and insulin secretion capacity.

**Results:** The results showed that while no amino acid tested had beta cell protective effects, some showed beta cell toxicity including insulinotropic amino acids L-alanine and L-arginine and branched chain amino acid L-valine. L-alanine and L-valine significantly decreased glucose stimulated insulin secretion ( $-22\% \pm 5.3\%$ ,  $p < 0.05$ ) at elevated 10 mM levels. The amino acid L-arginine was particularly beta cell toxic causing a dose dependant decrease in insulin secretion becoming significant at 1 mM with a 75% reduction at 10 mM ( $p < 0.01$ ). This was accompanied by a significant decrease in beta cell proliferation as measured by EdU incorporation ( $-30\%$  at 1 mM,  $p < 0.05$ ) and increased beta cell apoptosis as measured by annexin V. We hypothesised that arginine induced production of nitric oxide was the mechanism underlying beta-cell dysfunction however its effects were not blocked by NOS inhibitors L-NAME and Aminoguanidine, and beta cell nitrite levels and iNOS expression remained unchanged. Dysregulated cytosolic calcium concentration is a potent signal for apoptosis and basal calcium concentrations were found to be significantly elevated in L-arginine treated beta cells ( $p < 0.05$ ), indicating that sustained calcium influx may be the mechanism responsible its toxic effect.

**Conclusion:** In conclusion these results show for the first time that altered amino acid levels in obesity may impact on beta cell function providing a further link between obesity and type 2 diabetes.

### MST1 mediates beta cell failure by targeting BIM and destabilising PDX1

A. Ardestani<sup>1</sup>, F. Paroni<sup>1</sup>, J. Kerr-Conte<sup>2</sup>, K. Maedler<sup>1</sup>;<sup>1</sup>Centre for Biomolecular Interactions, University of Bremen, Germany,<sup>2</sup>University of Lille, Lille, France.

**Background and aims:** Pancreatic β-cell death is the fundamental cause of type 1 and type 2 diabetes. Mammalian sterile 20-like kinase 1 (MST1) is a serine threonine kinase, which mediates apoptosis in response to cytotoxic stress. MST1 is both, cleaved and activated by caspases, and in turn activates caspases to amplify the apoptotic signaling pathways. MST1 is induced in β-cells under diabetic conditions, which may be a major common pathway of β-cell death in diabetes. Here we examined the mechanism by which MST1 mediates β-cell failure.

**Materials and methods:** Isolated human islets and the rat β-cell line INS1 were exposed to a diabetic milieu (IL-1β/IFNγ, H<sub>2</sub>O<sub>2</sub> or increasing glucose concentrations). Phospho-MST1 and MST1 cleavage, Pancreatic Duodenal Homeobox-1 (PDX1), the apoptotic mitochondrial pathway and β-cell apoptosis (caspase-3, -9 & PARP) were analyzed by western blotting. MST1 was overexpressed by adenoviral-delivery or plasmid transfection, MST1 inactivation was performed by overexpressing dominant-negative MST1 (dn-MST1) or a stable MST1-deficient INS1 cell clone was produced by lentiviral

MST1 small hairpin RNA (shRNA) transfection. Lentiviral MST1 shRNA and pools of specific siRNA was also used to knock down MST1 in human islets. PDX1 turnover & ubiquitination was performed in HEK 293 cells over-expressing PDX1 and MST1.

**Results:** MST1 cleavage & phosphorylation was increased in human islets and INS1 cells exposed to IL-1β/IFNγ, H<sub>2</sub>O<sub>2</sub> or increasing glucose concentrations (22.2 and 33.3 mM). This correlated with increased β-cell apoptosis, impaired function, decreased PDX1, BCL2 and increased BAX, BIM, cytochrome c release and activation of caspase-9 and -3, indicating activation of the mitochondrial pathway. Overexpression of MST1 increased β-cell apoptosis and reduced GSIS, indicating that MST1 alone is sufficient to promote β-cell failure. The intrinsic cell death pathway as a mediator of MST1-induced β-cell apoptosis was confirmed by co-culture with BAX inhibitory peptide, which diminished caspase cleavage (9 and 3) and apoptosis. MST1 overexpression in islets, INS-1 cells as well as in PDX1 overexpressing HEK293 cells strongly decreased PDX1 without changes in PDX1 mRNA levels; this demonstrated that the decrease in PDX1 expression was regulated at the post-transcriptional level and related to its reduced stability. MST1 overexpression caused PDX1 shuttling from the nucleus to the cytosol, its ubiquitination and subsequent degradation, which occurred by direct MST1-induced phosphorylation of PDX1 through physical interaction of with MST1. MST1-induced PDX1 degradation was inhibited by the proteasome inhibitor MG132, indicating ubiquitin-proteasome mediated PDX1 proteolysis. MST1-knock down in human islets and INS-1 cells protected β-cells from gluco- and cytokine-toxicity; it improved survival as well as β-cell function through downregulation of BIM and restoration of PDX1, indicating a major role of BIM and PDX1 in the mechanism of stress-induced beta cell apoptosis.

**Conclusion:** Our results show that MST1 plays an important role in triggering β-cell death via targeting proapoptotic BIM and destabilizing prosurvival signal PDX1. Its inhibition provides a new strategy to restore β-cell survival and function.

### Identification of new mitochondrial molecular targets in INS-1E beta cells exposed to metabolic stresses associated with diabetes

T. Brun<sup>1</sup>, D. Duhamel<sup>1</sup>, P. Scarica<sup>2</sup>, P. Gaudet<sup>3</sup>, A. Bairochi<sup>3</sup>, F. Palmieri<sup>2</sup>, P. Maechler<sup>1</sup>;<sup>1</sup>Department of Cell Physiology and Metabolism, University of Geneva,Switzerland, <sup>2</sup>Department of Pharmacology-Biology, University of Bari, Italy,<sup>3</sup>Swiss Institute of Bioinformatics, University of Geneva, Switzerland.

**Background and aims:** Exposure of beta-cells to stress conditions, such as high glucose, fatty acids and oxidative stress, interrupts the transduction of signals normally coupling glucose metabolism to insulin secretion, mitochondria playing a central role in this process. Several questions remain open on the respective contributions of the different diabetes-associated stresses and accompanying beta-cell dysfunction. Here, we aimed at identifying putative molecular targets shared by the different metabolic stresses investigated in the same study using new powerful expression profiling approach.

**Materials and methods:** We designed a molecular screening array (Mito-array) based on pre-loaded micro fluidic card Real Time PCR system. INS-1E cells were cultured for 3 days in different conditions: 1) basal 5.6 mM glucose 2) intermediate 11.6 mM glucose 3) high 25 mM glucose 4) 0.4 mM palmitate 5) 0.4 mM oleate 6) after transient oxidative stress (200 μM H<sub>2</sub>O<sub>2</sub> for 10 min). The Mito-array allowed analysis of 60 selected genes with a particular interest for mitochondrial carriers of the Slc25a family. Molecular targets of interest have been further evaluated at the protein level by immunoblotting. The expression profile was then coupled with bio-informatics tools to delineate comprehensive networks.

**Results:** We first validated our gene expression data with selected markers previously identified in each specific condition. The expression of several energy sensors, key transcription factors and metabolic related enzymes were markedly diminished by high glucose (*Ampk*, *Pdx-1*, *Gk*), oxidative stress (*Pgc1a*, *Tfam*, *Cs*, *Mdh2*) or both (*Sirt1*, *Sirt4*, *Mafa*, *Ppara*, *PC*); whereas exposure to fatty acids did not alter their transcript and protein levels. High glucose and oxidative stress promoted cell death through caspase 3 cleavage activation, while palmitate induced ER stress without causing apoptosis. Among the 60 genes of interest investigated by Mito-array, we identified 22 mitochondrial carriers of the Slc25a family. High glucose selectively up-regulated protein levels of the citrate/isocitrate carrier (CIC), the dicarboxylate transporter (DIC) and the glutamate transporter (GC1). This is compatible with high activities of mitochondrial anaplerotic/cataplerotic pathways and

NADPH-generating shuttles. Both fatty acids increased expression of the carnitine/acylcarnitine carrier (CAC).

**Conclusion:** Expression of mitochondrial solute carriers was altered selectively by the different metabolic stresses, exhibiting stress-specific signatures. Due to the complexity of the alterations induced by the different stresses and the number of genes investigated, an innovative approach using bioinformatics tools is proposed, in order to obtain a comprehensive view of these results.

### Quantification of hydrogen peroxide generation within the endoplasmic reticulum by using the $H_2O_2$ -sensitive biosensor HyPer in insulin-producing cells

I. Mehmeti, S. Lortz, S. Lenzen;

Institute of Clinical Biochemistry, Hannover Medical School, Germany.

**Background and aims:** Oxidative protein folding in the endoplasmic reticulum (ER) is associated with the formation of native disulfide bonds. This process is catalysed by thiol-disulfide oxidoreductases PDI (protein disulfide isomerase) and ERO-1 (ER oxidoreductin 1) inevitably leading to hydrogen peroxide ( $H_2O_2$ ) generation. Especially in cells with very high secretory activity, such as pancreatic  $\beta$ -cells, the  $H_2O_2$  molecules generated during the oxidative protein folding could represent a significant oxidative burden. Therefore the aim of this study was to quantify the  $H_2O_2$  generation during disulfide bond formation in living insulin-producing cells by targeting and specifically expressing the  $H_2O_2$ -sensitive biosensor HyPer into the ER.

**Materials and methods:** For quantification of compartment-specific  $H_2O_2$  concentrations in living insulin-producing cells, the  $H_2O_2$ -sensitive biosensor HyPer was specifically expressed in cytosol (Cyto-HyPer), peroxisomes (Peroxi-HyPer), mitochondria (Mito-HyPer) or in the ER (ER-HyPer). The changes of the HyPer fluorescence ratio, which represents the  $H_2O_2$  concentration, were assessed fluorometrically and microscopically. The redox state of HyPer in various cell organelles was analysed by treatment of the HyPer expressing cells with 0.5 mM dithiothreitol (DTT). Additionally, the ER-resident  $H_2O_2$ -metabolizing peroxiredoxin 4 (PRDX4) was stably overexpressed to determine the specificity of the HyPer protein for the quantification of  $H_2O_2$  within the ER.

**Results:** Stable expression of the  $H_2O_2$ -sensitive HyPer protein targeted to various cell organelles revealed that the fluorescence ratio of HyPer in the ER was significantly higher than in all other investigated cell organelles, indicating high basal  $H_2O_2$  concentrations in this organelle. Treatment of the Cyto-, Peroxi-, Mito- and ER-HyPer expressing cells with the disulfide-bond-reducing agent DTT resulted in an extreme decrease of the HyPer fluorescence ratio in the ER, suggesting that ER-HyPer is completely oxidized. However, the overexpression of the ER-resident  $H_2O_2$ -metabolizing peroxiredoxin 4 had no impact on the observed ER-HyPer fluorescence ratio, although the overexpression of PRDX4 successfully prevented  $H_2O_2$ -mediated toxicity.

**Conclusion:** These data provide evidence that the oxidation of the  $H_2O_2$ -sensitive HyPer protein in the ER solely reflects the ER luminal oxidizing thiol-disulfide milieu and not the  $H_2O_2$  generation. Thus, the HyPer protein is an unsuitable tool for  $H_2O_2$  monitoring during disulfide bond formation in the ER. Furthermore the results clearly show on the other side that overexpression of ER-resident peroxiredoxin 4 is able to protect insulin-producing cells against oxidative injury when exposed to external  $H_2O_2$ , indicating that PRDX4 is a potential  $H_2O_2$  scavenger within the ER.

## 525

### Pancreatic beta cell proliferation by intermittent hypoxia via up-regulation of Reg family genes

S. Takasawa<sup>1</sup>, H. Ota<sup>2</sup>, A. Itaya-Hironaka<sup>1</sup>, A. Yamauchi<sup>1</sup>, S. Sakuramoto-Tsuchida<sup>1</sup>, T. Miyaoka<sup>1</sup>, T. Fujimura<sup>1</sup>, H. Tsujinaka<sup>1</sup>, K. Yoshimoto<sup>1</sup>, S. Tamaki<sup>1</sup>, H. Kimura<sup>2</sup>;

<sup>1</sup>Biochemistry, <sup>2</sup>Internal Medicine, Nara Medical University, Kashihara, Japan.

**Background and aims:** Sleep apnea syndrome (SAS) is characterized by recurrent episodes of oxygen desaturation during sleep, the development of daytime sleepiness, and deterioration in the quality of life. Up to 30% of the adult populations in Western countries are thought to be affected by asymptomatic SAS and approximately 2-4% by symptomatic SAS. Accumulating evidence suggests the association of intermittent hypoxia (IH), a hallmark

of SAS, and type2 diabetes. The progression to type 2 diabetes is dependent on the compensatory responses of the pancreatic  $\beta$  cells that produce insulin. Hyperglycemia is known to increase the  $\beta$  cell replication, and therefore IH itself could also modify the ability of the pancreatic  $\beta$  cells to replicate. However, we have currently no knowledge of the direct impact of IH on pancreatic  $\beta$  cell proliferation. In the present study, using rat, hamster, and human pancreatic  $\beta$  cells, we investigated the direct effect of IH on  $\beta$  cell proliferation.

**Materials and methods:** Pancreatic  $\beta$  cell-derived cell lines (rat RINm5F cells, hamster HIT-T15 cells and human 1.1B4 cells) were exposed either to 64 cycles/24 h of IH (5 min hypoxia (1%  $O_2$ )/10 min normoxia (21%  $O_2$ )), sustained hypoxia (SH: 1%  $O_2$ ) or normoxia for 24 h. After the treatment, viable cell numbers and apoptosis were measured by WST-8 cleavage and TUNEL method, respectively. Real-time quantitative RT-PCR of regenerating gene (Reg) family genes (Reg I, PAP I/Reg2, PAP II/Reg III, PAP III, and Reg IV for rat, and REG Ia, REG Ib, REG III, HIP/PAP, and REG IV for human), and interleukin-6 (IL-6) was performed using normoxia-, IH-, or SH-treated RINm5F and 1.1B4 cell RNAs as template. Small interfering RNA (siRNA) for rat Reg family were introduced into RINm5F cells and the IH-induced RINm5F cell proliferation was measured by WST-8 cleavage assay.

**Results:** The cell numbers of HIT-T15, RINm5F and 1.1B4 cells were significantly increased by IH ( $P=0.0064$ ,  $0.0013$ , and  $0.013$ , respectively), whereas SH did not increase the numbers of these cells. IH did not increase the apoptosis of the  $\beta$  cells, suggesting that IH stimulates  $\beta$  cell proliferation. We next measured the mRNA levels of Reg family genes, which encode autocrine  $\beta$  cell growth factors, and found that Reg I, PAP II/Reg III, PAP III, and Reg IV mRNAs were significantly increased in rat RINm5F cells by IH and that REG Ia mRNA was specifically increased in human 1.1B4  $\beta$  cells by IH but not by SH. The knockdown experiments using rat Reg family gene siRNAs for Reg I, PAP II/Reg III, PAP III and Reg IV resulted in reduced IH-induced cell proliferation of RINm5F cells but the introduction of siRNA for PAP I/Reg2 did not change the IH-induced RINm5F cell proliferation. In addition, IH significantly increased the mRNA level of IL-6, which was reported to increase Reg family gene expression, in RINm5F and 1.1B4 cells.

**Conclusion:** The cyclic change of hypoxia-reoxygenation, which occurs in SAS patients, stimulates pancreatic  $\beta$  cell proliferation. In this process, up-regulation of Reg family genes could be involved. The IH-induced expression of IL-6 may be a trigger for the up-regulation of Reg family genes.

## 526

### Hypoxia modifies intracellular free $Zn^{2+}$ concentration in pancreatic beta cells by altering the expression of the metallothionein and zinc transporter genes Slc30a8 / Slc39a6

P.A. Gerber, E.A. Bellomo, G.A. Rutter;

Section of Cell Biology, Department of Medicine, Imperial College, London, UK.

**Background and aims:** The endocrine pancreas is one of the best vascularised tissues, and insufficient supply with oxygen impairs the function of pancreatic islets. This is of particular importance in the setting of islet isolation and transplantation, but there is also evidence that hypoxia regulates islet function in type 2 diabetes (T2D) as well as in a low-oxygenated subpopulation of islets that form a functional reserve of endocrine cells.  $Zn^{2+}$  is an important cofactor for insulin biosynthesis and storage in pancreatic  $\beta$ -cells and is tightly controlled by transporters and binding proteins including the T2D-associated gene Slc30a8 (ZnT8). Here, we explore the effects of hypoxia on the regulators of  $Zn^{2+}$  homeostasis.

**Materials and methods:** Isolated murine pancreatic islets as well as dispersed islet cells were exposed to hypoxia (1% oxygen) or normoxia (21% oxygen) for 24 hours. After exposure, mRNA was isolated and quantified relatively to the expression of cyclophilin by qRT-PCR. The cytosolic concentration of free zinc ( $[Zn^{2+}]_{cy}$ ) in dispersed islet cells was measured using our newly developed FRET-based  $Zn^{2+}$  probe eCALWY-4, which was delivered to cells by adenoviral transfection.

**Results:** After 24 hours of hypoxia exposure of intact isolated islets, the gene expression of the metallothionein 1 and 2 genes (MT1, MT2) was up-regulated by a factor of  $6.9 \pm 2.7$  ( $p < 0.05$ ) and  $7.5 \pm 1.8$  ( $p < 0.01$ ), respectively. The expression of the zinc transporter ZiP6, encoded by Slc39a6, was increased by  $1.8 \pm 0.3$  ( $p < 0.05$ ), whereas the expression of ZnT8, encoded by Slc30a8, was decreased to  $0.2 \pm 0.0$  ( $p < 0.001$ ) compared to islets that were cultured under normoxic conditions (figure). To a lesser extent, similar changes were observed in dispersed islet cells after exposure to hypoxia (fold induction compared to cells under normoxic conditions: MT1  $2.5 \pm 0.1$ , MT2  $3.0 \pm 0.2$ ,

ZiP6  $1.6 \pm 0.2$ , ZnT8  $0.5 \pm 0.1$ ;  $p < 0.05$  for all measurements).  $[Zn^{2+}]_{\text{cyt}}$  tended to be decreased after exposure to hypoxia for 24 hours when compared to normoxic islets ( $309 \pm 54 \text{ pmol/l}$  vs.  $425 \pm 284 \text{ pmol/l}$ ,  $n=3$ ).

**Conclusion:** We demonstrate that exposure to hypoxia up-regulates metallothionein gene expression and alters the expression of 2 zinc transporters with very high abundance in the pancreatic  $\beta$ -cell, ZiP6 and ZnT8. Whereas an increase in metallothionein expression may decrease  $[Zn^{2+}]_{\text{cyt}}$ , and increased ZiP6 and decreased ZnT8 activity would promote an increase in  $[Zn^{2+}]_{\text{cyt}}$ . The concentration of  $[Zn^{2+}]_{\text{cyt}}$  in dispersed islet cells tended to decrease after 24 hours of hypoxia exposure, but further investigation is necessary to dissect the impact of the altered metallothionein and zinc transporter gene expression levels on cytosolic zinc concentrations under hypoxia. Changes in intracellular zinc homeostasis are thus involved in the response of  $\beta$  cells to hypoxia and might be a target for strategies aimed at improving cell survival *in vitro* prior to transplantation.

**Proinsulin homeostasis in beta cells is sensitive to oxidative stress and its disorder and toxic consequences can be alleviated by administration with antioxidants**

Q. Yuan<sup>1,2</sup>, K. Osei<sup>1</sup>, J. Wang<sup>1</sup>;

<sup>1</sup>Division of Endocrinology, Diabetes, and Metabolism, Department of Internal Medicine, The Ohio State University, Columbus, USA,

<sup>2</sup>Endocrinology and Metabolism, The First Affiliated Hospital of Nanjing Medical University, China.

**Background and aims:** Proinsulin with a low relative folding rate maintains a homeostatic balance of natively and plentiful non-natively folded states (i.e., proinsulin homeostasis, PIHO) in  $\beta$ -cells. Also, findings in our recent study have suggested that the contrast of low relative folding rate with plentiful amounts of insulin precursor manufactured in  $\beta$ -cells renders PIHO susceptible to genetic and environmental influences, and a disturbed PIHO would result in various toxic consequences that critically link to  $\beta$ -cell failure and diabetes. To explore this hypothesis, we further characterized the susceptibility of PIHO to oxidative stress and the effect of antioxidants on PIHO disorder and toxic consequences in  $\beta$ -cells.

**Materials and methods:** Oxidative stress inducer hydrogen peroxide ( $H_2O_2$ ) and/or antioxidants including dithiothreitol, glutathione, N-acetylcysteine, and vitamin C were applied in this study in the *Ins2<sup>+/Akita</sup>* (C96Y)  $\beta$ -cells that

preserve an oxidative stress consequence and wild-type control *Ins2<sup>+/+</sup>*  $\beta$ -cells. We applied immunoblotting, immunoprecipitation, and morphological studies and examined changes in the cellular proinsulin states, secreted insulin, and death rates of these two line  $\beta$ -cells under oxidative stress and with/without antioxidant conditions. Statistical analyses are performed using Student's t-test (2-tailed) or analysis of variance if appropriate, with  $P < 0.05$  considered statistically significant.

**Results:** An increase in the proportion of non-natively folded proinsulin aggregation in *Ins2<sup>+/+</sup>*  $\beta$ -cells was induced by addition of  $H_2O_2$  at low nanomolar concentrations during a 60-minute post-translational process compared to the control with no addition of  $H_2O_2$  ( $P < 0.01$ ). Correspondingly, a decrease was evident in the proportion of fully folded proinsulin monomers and in the consequently secreted insulin. These changes were induced by  $H_2O_2$  in a dose-dependent manner. Moreover, addition of 10  $\mu M$  but not 1  $\mu M$   $H_2O_2$  for 24 or 48 hours induced an increased cell death compared to the control with no addition of  $H_2O_2$  ( $P < 0.05$ ) despite addition of 10  $\mu M$  or 1  $\mu M$   $H_2O_2$  all induced a disorder in the PIHO of *Ins2<sup>+/+</sup>*  $\beta$ -cells. Intervention with the above mentioned antioxidants partially eliminated the PIHO disorder and toxic consequences in insulin secretion and cell survival, which were primarily induced by  $H_2O_2$  in *Ins2<sup>+/+</sup>*  $\beta$ -cells and by the C96Y mutation in the *Ins2* gene in *Ins2<sup>+/Akita</sup>*  $\beta$ -cells.

**Conclusion:** The findings in this study clearly demonstrated that proinsulin homeostasis in normal  $\beta$ -cells is sensitive to oxidative stress because perturbation of PIHO can be induced by  $H_2O_2$  at nanomolar concentrations but this level of  $H_2O_2$  is unable to induce  $\beta$ -cell death. The data also suggest that administration with antioxidants can alleviate PIHO disorders and toxic consequences that associate to oxidative stress in  $\beta$ -cells.

## 528

**Glucagon-like peptide-1 induces antioxidant enzymes via extracellular regulated kinase pathway in beta cells**

E. Fernández-Millán<sup>1,2</sup>, J. De Toro-Martín<sup>1</sup>, E. Lizárraga-Mollinedo<sup>1,2</sup>, S. Ramos<sup>3</sup>, L. Goya<sup>3</sup>, F. Escrivá<sup>1,2</sup>, M.A. Martín<sup>3</sup>, C. Álvarez<sup>1,2</sup>;

<sup>1</sup>Bioq. y Biol. Mol. II, Facultad de Farmacia, UCM, <sup>2</sup>Ciberdem, ISCIII,

<sup>3</sup>Instituto de Ciencia y Tecnología de Alimentos y Nutrición, CSIC, Madrid, Spain.

**Background and aims:** One of the major factors for progressive loss of  $\beta$ -cell function and mass in type 2 diabetes is glucotoxicity. Long-term hyperglycemia induces massive generation of reactive oxygen species (ROS) leading to chronic oxidative stress.  $\beta$ -cells are extremely sensitive to oxidative stress because of their low levels of antioxidant enzymes. Redox-sensitive transcription factor nuclear factor erythroid 2-related factor 2 (Nrf2) plays a pivotal role in the cellular defence against oxidative stress via transcriptional upregulation of phase II defence enzymes and antioxidant stress proteins. The incretin hormone glucagon-like peptide-1 (GLP-1) protects  $\beta$ -cells from oxidative stress-induced apoptosis both *in vivo* and *in vitro*. However the signalling pathways involved are not fully defined. To gain insight into the mechanisms by which GLP-1 protects  $\beta$ -cells from oxidative stress-derived effects we have used an *in vitro* model of oxidative stress induced by tert-butyl hydroperoxide (*t*-BOOH).

**Materials and methods:** INS-1E cells treated for 20h with GLP-1 were further exposed to *t*-BOOH for 2h and ROS generation at different times (5–120 min) and cell death at 2h were measured by 2',7'-dichlorofluorescein (DCFH) and crystal violet assays, respectively. The content of reduced glutathione (GSH) was quantified by a fluorometric assay and glutathione peroxidase (GPx) and glutathione reductase (GR) activities were analyzed indirectly. To elucidate the upstream signalling pathways involved in the activation of GR and GPx, specific inhibitors were used. Finally, to study the effect of GLP-1 on Nrf2 translocation, nuclear and cytosolic extracts were obtained and WB against Nrf2 was performed.

**Results:** Pre-treatment of cells with GLP-1 significantly reduced the generation of ROS caused by *t*-BOOH and suppressed the deleterious effect induced by the pro-oxidant. Since induction of antioxidant defences is considered crucial to protect cells against oxidative injuries we evaluated the effect of GLP-1 treatment on the activity of GPx and GR enzymes. Long-term treatment of GLP-1 enhanced GPx and GR activities and GSH content in a dose-dependent manner. The inhibition of PKA and Erks completely blocked the cytoprotective effect of GLP-1 whereas no effect was observed when Akt was inhibited. GLP-1 also induced Nrf2 transcription factor activation. Pre-treatment of cells with GLP-1 for 3, 6 and 20h, increased the protein levels of Nrf2 in the nucleus at 3 h, peaked at 6 h and then declined at 20 h of treatment.

**Conclusion:** Herein we show that GLP-1 is able to enhance the cellular antioxidant defence capacity of  $\beta$ -cells, by increasing the activity of GPx and GR enzymes via a mechanism that involves activation of Erks in a PKA-dependent manner and translocation of Nrf2. In conclusion, our results provide an additional mechanism of action of GLP-1 to prevent oxidative damage in  $\beta$ -cells through the modulation of signalling pathways involved in antioxidant enzyme regulation.

## 529

### Increasing expression of UCP2 in mouse beta cells partially prevents secretory dysfunction induced by glucotoxic conditions and oxidative stress

N. Li, F. Assimacopoulos-Jeannet, P. Maechler;

Department of Cell Physiology and Metabolism, University of Geneva, Switzerland.

**Background and aims:** The function of uncoupling protein 2 (UCP2) in pancreatic beta-cells is debated, both in terms of putative mitochondrial uncoupling properties and effects on glucose-stimulated insulin secretion. In this context, recent studies suggest a protective role for UCP2 in stress conditions. Here, we questioned protective capacity of UCP2 under oxidative stress and glucotoxic culture conditions using transgenic mice with beta-cell-specific overexpression of human UCP2 (RIP-UCP2).

**Materials and methods:** Islets isolated from littermate wild type (WT) control and RIP-UCP2 mice were challenged with single transient oxidative stress (200  $\mu$ M H<sub>2</sub>O<sub>2</sub> for 10 min) and analysed either right after stress (acute stress) or after a recovery culture period (3 days post-stress). Alternatively, glucotoxicity was induced by culturing islets with 30mM glucose (versus 11mM for standard culture) for 7 days. We measured glucose-induced insulin secretion (RIA), UCP2 protein expression (immunoblotting), mitochondrial membrane potential (rhodamine-123), intracellular superoxide generation (DHE), and apoptosis (ELISA).

**Results:** In control no-stress conditions, RIP-UCP2 islets exhibited similar secretory responses to 22.8mM glucose compared to WT islets. In acute oxidative stress conditions, i.e. immediately after 10min exposure to H<sub>2</sub>O<sub>2</sub>, both WT and RIP-UCP2 islets totally lost the glucose response. Three days after transient oxidative stress, the rate of insulin secretion at stimulatory 22.8mM glucose in WT and RIP-UCP2 islets was back to normal. However, basal release at 2.8mM glucose was 1.7-fold higher in WT islets compared to non stressed islets, while RIP-UCP2 islets exhibited normal low basal secretion (-51%,  $p < 0.05$  versus WT). In glucotoxic conditions, i.e. after 7 days culture at 30mM glucose, basal insulin release and glucose-stimulated secretion were increased in WT islets compared to 11mM glucose conditions (12- and 4.2-fold respectively, both  $p < 0.01$ ), thereby reducing the glucose response. RIP-UCP2 islets maintained in glucotoxic conditions exhibited lower basal and stimulated insulin secretion rates (-56% and -40% respectively versus WT islets,  $p < 0.001$ ), partially preserving the glucose response. No mitochondrial uncoupling was observed in RIP-UCP2 islets when cultured at 11mM glucose. In glucotoxic conditions, RIP-UCP2 islets showed partially preserved glucose-induced mitochondrial hyperpolarisation, which was markedly impaired in WT islets (-42% in WT and -15% in RIP-UCP2 islets,  $p < 0.05$ ). Preliminary data indicated similar superoxide production and cell death in WT and RIP-UCP2 islets.

**Conclusion:** UCP2 did not exhibit uncoupling properties. Increasing beta-cell UCP2 partially protected against glucotoxic conditions and oxidative stress, mainly by preserving low basal insulin release and mitochondrial glucose response.

### Expression of the TXNIP gene is influenced by histone modifications in INS1 832/13 cells

M. Cai<sup>1</sup>, O. Kotova<sup>2</sup>, Y. de Marinis<sup>1</sup>, L. Groop<sup>1,3</sup>;

<sup>1</sup>Department of Clinical Science, Diabetes and Endocrinology, Lund University, Skåne University Hospital, Malmö, Sweden, <sup>2</sup>Department of Clinical Science, Lund University, Skåne University Hospital, Malmö, Sweden, <sup>3</sup>Institute for Molecular Medicine Finland FIMM, University of Helsinki, Finland.

**Background and aims:** Thioredoxin-interacting protein (TXNIP) has been identified as a mediator of glucotoxicity in pancreatic B cells, but the mechanisms are not fully understood. High glucose has been suggested to increase binding of a carbohydrate-response element-binding protein (ChREBP) to TXNIP promoter, but it could also influence the chromatin. This study was designed to test whether glucose can influence TXNIP expression by causing histone modifications.

**Materials and methods:** We treated INS1 832/13 cells with 5 mM, 16.7 mM and 25 mM glucose for 4 h and measured TXNIP mRNA expression by quantitative RT-PCR. Histone modifications were analyzed by Chromatin immunoprecipitation (ChIP) using antibodies against H3K9 acetylation, H3K4me3 and H3K27me3.

**Results:** Incubating INS1832/13 cells with 16.7 mM and 25 mM glucose increased TXNIP mRNA 4.6-fold ( $p = 0.0019$ ) and 5.8-fold ( $p = 0.0000$ ), respectively, as compared to expression at 5 mM glucose. The same glucose concentrations also induced a 2.6-fold and 3.6-fold increase in H3K9 acetylation (both  $p = 0.04$ ). High glucose (25 mM) increased a 1.76-fold trimethylation at H3K4 ( $p = 0.04$ ) and decreased trimethylation (-35.35%) at H3K27 ( $p = 0.04$ ). There was a strong positive correlation between H3K9 acetylation at 16.7 mM glucose and increase in TXNIP expression ( $r = 0.831$ ;  $p = 0.04$ ).

**Conclusion:** Glucose induced increase in H3K9 acetylation may contribute to increased TXNIP expression in clonal beta-cells and thereby contribute to glucotoxicity.

## PS 031 Beta cell apoptosis and survival

531

### Glucose-induced ER stress in beta cells induces CHOP-mediated activation of the intrinsic apoptosis pathway

J.A. Wali<sup>1,2</sup>, T.W. Kay<sup>1,2</sup>, H.E. Thomas<sup>1,2</sup><sup>1</sup>St Vincent's Institute, <sup>2</sup>University of Melbourne, Melbourne, Australia.

**Background and aims:** Type-2 diabetes is caused by declining function and increased apoptosis of beta-cells in insulin-resistant subjects. Chronic hyperglycemia is considered a potential cause of this beta-cell death. High glucose concentrations induce apoptosis of islet cells *in vitro* through the intrinsic pathway. Specifically, the pro-apoptotic BH3-only proteins Bim and Puma are required. We studied intrinsic pathway activation in response to glucose and ribose-induced ER stress.

**Materials and methods:** Islets isolated from wild-type (B6), Bim<sup>-/-</sup>, Puma<sup>-/-</sup> or CHOP<sup>-/-</sup> mice were cultured for 4–6 days in 33.3 mM glucose or 50 mM ribose (a reducing sugar similar to glucose), together with the ER stress inhibitors tauroursodeoxycholic acid (TUDCA 0.5 mM) or phenylbutyric acid (PBA 2.5 mM). Islets were incubated with Thapsigargin (5  $\mu$ M) for 1 or 5 days. Apoptosis was measured by flow cytometric analysis and ER stress factors were studied in ribose treated (1–3 days) islets by qPCR and western blotting. **Results:** Bim<sup>-/-</sup> and Puma<sup>-/-</sup> mice had normal glucose tolerance, and glucose stimulated insulin secretion (GIS) of isolated islets was similar to wild-type mice. This suggested that Bim and Puma deficient islets are functionally normal. Ribose treatment of wild-type, Bim or Puma deficient islets produced a similar decrease in GIS. Loss of Bim or Puma partially protected islets from Thapsigargin toxicity indicating that the intrinsic apoptosis pathway is involved in ER stress induced cell death. Inhibition of ER stress with TUDCA or PBA partially protected wild-type islets, and completely protected Bim<sup>-/-</sup> or Puma<sup>-/-</sup> islets from ribose and glucose toxicity. This showed that Bim and Puma play overlapping and additive roles in mediating this apoptosis. Ribose treatment for 3 days increased JNK phosphorylation and XBP1 splicing (1.73 $\pm$ 0.10 fold) but did not increase mRNA of ER chaperones (BiP, Pdia4, P58), or BiP protein expression in wild-type islets. Gene and protein expression of the ER stress transcription factor CHOP was significantly increased (1.6 $\pm$ 0.08 fold) in ribose-treated wild-type islets compared with untreated islets, and islets deficient in CHOP were partially protected from ribose and glucose toxicity. These results suggest there is activation of the IRE1 $\alpha$  (p-JNK, XBP1s) and PERK (CHOP) arms, and inactivation of the ATF6 arm (chaperones) of the ER stress pathway in ribose treated islets. CHOP and BiP mRNA expression was significantly lower in islets of Bim<sup>-/-</sup> mice (CHOP: 0.54 $\pm$ 0.12 fold), and to a lesser extent in islets of Puma<sup>-/-</sup> mice. Incubation of wild-type islets with ribose+TUDCA reduced gene expression of CHOP (0.8 $\pm$ 0.10 fold) and upstream factor ATF4 (0.56 $\pm$ 0.18 fold). Gene expression of Bim and Puma also decreased after TUDCA exposure (Ribose vs Ribose+TUDCA). These results suggested that down-regulation of CHOP protects islets from cell death mediated by the intrinsic apoptosis pathway.

**Conclusion:** Our results suggest that ER stress plays an important role in glucose and ribose-induced killing of islet-cells *in vitro*. Glucose toxicity activates the pro-apoptotic factors in the ER stress pathway including CHOP, JNK and XBP1, and this activates the intrinsic apoptosis factors Bim and Puma. Up-regulation of the upstream ER stress transcription factor CHOP is important in mediating intrinsic pathway activation in islets in response to ribose and glucose toxicity.

### Losartan protects human pancreatic islets from glucotoxicity by interfering with the activation of the phospholipase C (PLC)/Calcium signalling pathway

R. Cassel<sup>1</sup>, S. Ducreux<sup>2</sup>, S. Dubois<sup>1</sup>, G. Vial<sup>1</sup>, M.-A. Chauvin<sup>1</sup>, J. Riusset<sup>1</sup>, F. Van Coppenolle<sup>2</sup>, C. Thivolet<sup>1</sup>, A.-M. Madec<sup>1</sup><sup>1</sup>Faculté de Médecine Lyon Sud, CarMeN Inserm U1060, Oullins <sup>2</sup>Université Claude Bernard Lyon1, UMR CNRS 5534, Lyon, France.

**Background and aims:** Chronic high glucose (HG) concentrations induce beta cell injury and contribute to the progressive incapacity of glucose control in patients with type 2 diabetes. As potential mechanisms, HG levels increase

reactive oxygen species (ROS) production and induce endoplasmic reticulum (ER) stress leading to beta cell death by apoptosis and necrosis. We have previously shown that Losartan, an angiotensin II Type-1 receptor (AT1R) blocker, reduces the deleterious effects of HG on human islets by reducing oxidative and ER stress. The aim of this study was to investigate the mechanisms of the protective effects of Losartan on mitochondrial function and calcium homeostasis in human islets and murine beta cell line exposed to HG conditions.

**Materials and methods:** Human islets from 11 distinct donors were incubated for 96h in 5.5 or 16.7 mM glucose with or without Losartan for the last 48h, and/or with acute or chronic U-73122, a PLC inhibitor. MIN6B1 beta cells were cultured 48h in 5.5 mM or 16.7 mM with or without Losartan and/or PLC inhibitor the last 24h. ATP5B (ATP synthase mitochondrial) and UCP2 mRNA were evaluated by qRT-PCR. OxPhos, SERCA2b (sarco/endoplasmic reticulum ATPase) and IP3R2 (ER-resident inositol triphosphate receptors) proteins were measured by western-blot. Cytosolic calcium [Ca<sup>2+</sup>]<sub>i</sub> was measured in Ca<sup>2+</sup> free KRB on human islets loaded with Fura-2 AM. Thapsigargin, a SERCA pump blocker, was used to release reticular calcium [Ca<sup>2+</sup>]<sub>ER</sub>.

**Results:** In human islets, UCP2 mRNA level increased in HG conditions (x2.5;p<0.05), while Losartan prevented this effect (p<0.05). HG induced a significant reduction in mitochondrial respiratory chain complex I protein levels (p<0.01), complex III (p<0.05) and Complex V (p<0.05) as compared to control islets. Addition of Losartan up-regulated complex I (p<0.01) and complex V (p<0.05) subunits but not complex III. HG reduced the expression of ATP5B as compared to control islets (p<0.05). Losartan up-regulated this effect (p<0.01). The amounts of SERCA2b protein, the predominant SERCA isoform in islets with the highest Ca<sup>2+</sup> affinity, were decreased with high glucose (p<0.01). Losartan partially reversed this effect. [Ca<sup>2+</sup>]<sub>i</sub> and [Ca<sup>2+</sup>]<sub>ER</sub> contents were decreased in HG condition (0.39 $\pm$ 0.01 vs 0.52 $\pm$ 0.02; p<0.001; 0.14 $\pm$ 0.05 vs 0.47 $\pm$ 0.26; p<0.0001, respectively). Losartan rescued [Ca<sup>2+</sup>]<sub>i</sub> content (0.45 $\pm$ 0.02; N.S. vs controls), and partially [Ca<sup>2+</sup>]<sub>ER</sub> content (0.25 $\pm$ 0.04;p<0.01). AT1R activation stimulates PLC, a major calcium signalling pathway. Acute addition of U-73122 to HG had no effect on [Ca<sup>2+</sup>]<sub>i</sub> concentrations but restored [Ca<sup>2+</sup>]<sub>ER</sub> content (0.44 $\pm$ 0.05; N.S. vs controls). In Min6B1 cells, HG increased the ER intracellular Ca<sup>2+</sup>-releasing channel IP3R2 protein expression (p<0.02 vs controls) and chronic exposure to U-73122 reversed this effect as Losartan.

**Conclusion:** Chronic HG exposure of human islets induces oxidative stress by UCP2 activation, leading to ROS production. HG induced SERCA2b dysregulation and reduction in calcium content. Losartan prevents these deleterious effects by maintaining a robust pool of reticular Ca<sup>2+</sup>, which has a key role in beta cell function as insulin secretion and ER health. The PLC/IP3R2 calcium pathway is involved in this AT1R-blocker protective effect.

### Pancreatic beta cell failure mediated by mTORC1 hyperactivity and autophagic impairment

A. Bartolome<sup>1,2</sup>, M. Kimura-Koyanagi<sup>1</sup>, S. Shimizu<sup>1</sup>, A. Kanno<sup>1</sup>, C. Guillen<sup>2</sup>, M. Benito<sup>2</sup>, S.-I. Asahara<sup>1</sup>, Y. Kido<sup>1</sup><sup>1</sup>Health Sciences, Kobe University, Kobe, Japan, <sup>2</sup>Biochemistry and Molecular Biology, Universidad Complutense, Madrid, Spain.

**Background and aims:** Hyperactivation of the mammalian target of rapamycin complex 1 (mTORC1) in  $\beta$  cells is usually found in progression to type 2 diabetes. Although it has an essential role in  $\beta$  cell compensatory mechanisms, mTORC1 negatively regulates autophagy, a cytoprotective process. mTORC1 hyperactivity is also a well-described cause of endoplasmic reticulum stress and insulin resistance. We focused on the role that mTORC1 hyperactivation might be having on  $\beta$  cell failure.

**Materials and methods:** Using a mouse model with  $\beta$  cell specific deletion of TSC2 ( $\beta$ TSC2KO) and consequently mTORC1 hyperactivation, processes such as autophagy, mitophagy and ER stress were analyzed. Pancreatic sections or isolated islets were used for western blot, immunohistochemistry and laser scanning confocal microscopy of single intact islets for tomographic imaging of whole islets or single  $\beta$  cells within the islet.

**Results:** mTORC1 hyperactivation drives an increase in  $\beta$  cell mass mediated by cell hypertrophy. But from 40 weeks of age  $\beta$  cell mass decline and hyperglycemia appears, as we described before using  $\beta$ TSC2KO. We found FoxO1 nuclear accumulation through life, together with several apoptosis and ER-stress markers induced in islets of older  $\beta$ TSC2KO, as well as accumulation of p62/SQSTM1 and impaired ex vivo autophagic response of islets to diverse

stimuli. Mitochondrial mass is also increased on  $\beta$  cells of  $\beta$ TSC2KO mice, but interestingly several mitochondria with collapsed mitochondrial potential and positive p62/SQSTM1 staining accumulated in older islets, meaning that mitophagy together with autophagy is defective under mTORC1 hyperactivation in  $\beta$  cells.

**Conclusion:** Here we provide the in vivo evidence of  $\beta$  cell autophagy impairment as a link between mTORC1 hyperactivation and mitochondrial dysfunction, probably contributing to  $\beta$  cell failure.

### 14-3-3 proteins are required for pancreatic beta cell survival and glucose homeostasis

G.E. Lim<sup>1</sup>, M. Piske<sup>1</sup>, H.S. Ramshaw<sup>2</sup>, M.A. Guthridge<sup>3</sup>, A.F. Lopez<sup>2</sup>, J.D. Johnson<sup>1</sup>;

<sup>1</sup>Cellular and Physiological Sciences, University of British Columbia,

Vancouver, Canada, <sup>2</sup>Centre for Cancer Biology, Adelaide, Australia,

<sup>3</sup>Monash University, Melbourne, Australia.

**Background and aims:** Diabetes is caused by pancreatic  $\beta$ -cell death and dysfunction, which are regulated by survival and apoptotic signaling pathways. 14-3-3 proteins are molecular adaptors that integrate signaling pathways, but their roles in  $\beta$ -cell survival and glucose homeostasis are unknown. We previously reported that insulin protects  $\beta$ -cells by Raf1-mediated inhibition of Bad, both of which bind to 14-3-3 proteins. Furthermore, 14-3-3 proteins interact with effectors in insulin signaling pathways that mediate cell survival and glucose uptake. Therefore, we hypothesized that 14-3-3 proteins are crucial for  $\beta$ -cell survival and glucose homeostasis.

**Materials and methods:** To test the role of 14-3-3 proteins in  $\beta$ -cell fate and function, protein over-expression and siRNA were used in MIN6  $\beta$ -cells and mouse islets. Quantitative PCR and fluorescent microscopy were used to detect mRNA, protein localization, cell death, and proliferation. Insulin secretion was measured by RIA. Protein interactions and phosphorylation were detected by biochemical techniques. Systemic 14-3-3 $\zeta$  knockout (KO) mice were subjected to intraperitoneal glucose (2 g/kg) and insulin (0.75 U/kg) tolerance tests.

**Results:** All 14-3-3 isoforms are present in primary mouse islets with distinct patterns of distribution. Expression of difopein, a pan-14-3-3 inhibitor, promoted  $\beta$ -cell apoptosis, as observed by a 1.5-fold elevation ( $p<0.05$ ) in cleaved caspase-3 levels and increased localization of pro-apoptotic Bad in mitochondrial fractions. Difopein expression also attenuated insulin release from MIN6 cells and mouse islets. Isoform-specific knockdown revealed the involvement of the  $\zeta$ ,  $\theta$ , and  $\gamma$  isoforms in  $\beta$ -cell survival and proliferation. No effects on insulin release were observed after knockdown of each isoform, but up to 1.8-fold ( $p<0.05$ ) increases in insulin content were observed among isoforms. Over-expression of 14-3-3 $\zeta$  promoted survival following pro-inflammatory cytokine or thapsigargin exposure, in addition to decreased Bad and Bax in mitochondrial fractions. Exposure to insulin or GLP-1 increased binding of Bad and Bax with 14-3-3 $\zeta$ , suggesting their cytosolic sequestration. The inhibitory role of 14-3-3 $\zeta$  on Bad was further tested with 14-3-3 $\zeta$  binding-deficient Bad mutants, which increased cell death by up to 4-fold ( $p<0.05$ ) and promoted their mitochondrial localization. Over-expression of 14-3-3 $\zeta$  also significantly reduced the induction of pro-apoptotic DP5/Hrk and PUMA by cytokines. To examine its role in glucose homeostasis, 14-3-3 $\zeta$  KO were characterized. At 8 weeks of age, KO mice were glucose intolerant with normal insulin sensitivity, which deteriorated at 26 weeks of age. KO mice weighed 1.4-fold ( $p<0.05$ ) more than control mice. Random-fed plasma insulin and triglyceride levels were increased by 2.1- and 1.4-fold ( $p<0.05$ ), respectively, in KO mice.

**Conclusion:** The present study represents the first systematic analysis of the 14-3-3 protein family in  $\beta$ -cells. 14-3-3 $\zeta$  exerts its protective effects by affecting the localization and expression of apoptotic Bcl-2 proteins. Furthermore, loss of 14-3-3 $\zeta$  is associated with glucose intolerance and insulin resistance. Alterations in the expression of 14-3-3 proteins may represent a novel therapeutic approach to modulate insulin signaling and promote beta cell survival and function.

### Serine/threonine protein phosphatase 5 is involved in pancreatic beta cell apoptosis induced by dexamethasone

L. Fransson, Å. Sjöholm, H. Orsäter;

Department of Clinical Science and Education, Södersjukhuset, Unit for Diabetes Research, Karolinska Institutet, Stockholm, Sweden.

**Background and aims:** Patients subjected to long term treatment with glucocorticoids (GCs) are at risk of developing steroid induced diabetes. Insulin production, insulin secretion and  $\beta$ -cell viability are all parameters that are negatively affected by GC treatment. GCs exert their action by binding to the GC receptor (GR). However, several GR interacting proteins modulate GR activity in response to hormone binding. Non active GR in the cytosol is bound to an Hsp90 complex associated with serine/threonine protein phosphatase 5 (PP5; *Ppp5c*) and it has been proposed that PP5 can affect the phosphorylation status of the GR, and thus affect GR signalling. It has also been shown in lymphoid cells that activation of p38 MAPK is induced in response to GC exposure and that serine 211 of the human GR is a target for p38 MAPK. Thus PP5 and p38 MAPK may reciprocally control the phosphorylation status of the GR. This study was undertaken to monitor activation of p38 MAPK in response to a GC challenge and to investigate the role of PP5 for GC activity in pancreatic  $\beta$ -cells.

**Materials and methods:** MIN6 cells were exposed to 100 nmol/l of the GC dexamethasone (dexa) with or without 1  $\mu$ mol/l of the GR antagonist RU486 for 30 h or 100 nmol/l dexa with or without 10  $\mu$ mol/l of the p38 MAPK inhibitor SB203580. Apoptosis was evaluated by measuring cytoplasmic DNA-histone complexes with ELISA. Other MIN6 cells were transfected with an siRNA targeting PP5 or a non targeting siRNA and cultured with or without 100 nmol/l dexa for 30 h. Pancreatic islets from *Ppp5c*<sup>-/-</sup> mice and *Ppp5c*<sup>+/-</sup> littermates were isolated and exposed to 200 nmol/l dexa for 48 h. Proteins were extracted and levels of cleaved caspase 3 (CC3), as a measure of apoptosis, and phosphorylation of p38 MAPK were determined with Western blotting. Data are presented as mean $\pm$ SEM. Student's *t*-test or one way ANOVA was used for statistical comparison.

**Results:** Dexa significantly induced apoptosis in MIN6 cells, both as measured with ELISA and with levels of CC3. Dexa also significantly increased phosphorylation levels of p38 MAPK. These effects were mediated via the GR since it could be fully prevented by RU486. The apoptotic effect of dexa could also be partly prevented by the p38 MAPK antagonist. MIN6 cells with reduced levels of PP5 (mean PP5 down regulation 70%) were more sensitive to the apoptotic effect of dexa, both as measured with ELISA (neg. siRNA 185.7 $\pm$ 4.6% and PP5 siRNA 277.5 $\pm$ 14.3%  $p<0.05$ ) and levels of CC3 (neg. siRNA 734.0 $\pm$ 110.4% and PP5 siRNA 1040.0 $\pm$ 160.4%  $p<0.05$ ) compared to control cells. Also phosphorylation of p38 MAPK was induced by dexa to a greater extent in cells with reduced levels of PP5 (neg. siRNA 368.9 $\pm$ 70.71% and PP5 siRNA 523.6 $\pm$ 131.9%) compared to untreated cells. The same trend was seen in isolated islets from *Ppp5c*<sup>-/-</sup> mice, they were more sensitive to dexa induced apoptosis as measured with levels of CC3 (*Ppp5c*<sup>+/-</sup> 136.0 $\pm$ 32.7% and *Ppp5c*<sup>-/-</sup> 233.5 $\pm$ 57.1%) and they showed increased p38 MAPK phosphorylation (*Ppp5c*<sup>+/-</sup> 104.8 $\pm$ 7.9% and *Ppp5c*<sup>-/-</sup> 146.0 $\pm$ 13.7%) compared to control islets.

**Conclusion:** Our data show that MIN6 cells with reduced levels of PP5 and isolated pancreatic islets lacking PP5 are more sensitive to the cytotoxic effects of dexa, as seen by increased apoptosis. This increased sensitivity is mediated via a mechanism that involves enhanced activation of p38 MAPK. Thus PP5 is a regulator of GC action in pancreatic  $\beta$ -cells.

### Paracrine signalling loops in adult pancreatic islets: SLIT-ROBO signalling modulates adult beta cell survival

Y.H.C. Yang, J.D. Johnson;

Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, Canada.

**Background and aims:** Adult pancreatic islets contain multiple cell types that secrete well characterized hormones. Although it is becoming increasingly apparent that islets release and respond to more secreted factors than previously thought, systematic analyses are lacking. We have previously compiled a list of secreted factors and receptors that are expressed in adult mouse or human islets and discovered novel paracrine signaling loops within the islets,

including axon guidance factors important for neuronal development. The aim of the current study was to examine the pro-survival roles of SLIT-ROBO signaling in beta-cells. In addition to axon guidance, SLIT-ROBO signaling has also been implicated in the regulation of cell migration, angiogenesis and cell death during development of lung, kidney, liver and mammary glands.

**Materials and methods:** The expression of SLIT and ROBO family members were analyzed by quantitative RT-PCR, immunostaining, and western blotting. Mouse islet and MIN6 cells were treated with 10 nmol/L of SLIT-1 or SLIT-2 recombinant proteins in 5, 15, or 20 mmol/L glucose containing media. ER (endoplasmic reticulum) stress induced cell death was assessed by incorporation of propidium iodide, western blotting for members of the apoptosis pathway and qRT-PCR of ER stress related genes. Changes in cytosolic and ER luminal calcium levels were assessed by ratiometric imaging of cells loaded with Fura-2AM and transfected with FRET-based DIER camaleon, respectively.

**Results:** Immunostaining of adult islets revealed SLIT-2 expression exclusively in beta-cells, while ROBO1 and ROBO2 receptors were detected in beta-cells and alpha-cells. Exposing beta-cells to recombinant SLIT-2 under hyperglycemic conditions decreased thapsigargin induced cell death and down-regulated cleaved caspase-3 and CHOP protein levels. This was correlated with the decrease in Ask1-p38MAPK pathway activation and Xbp1 expression. SLITs are known to trigger repulsive axon guidance signals by regulating intracellular  $\text{Ca}^{2+}$  levels. In beta-cells, recombinant SLIT-1 and SLIT-2 treatments could deplete ER  $\text{Ca}^{2+}$  levels and increase cytosolic  $\text{Ca}^{2+}$  oscillations under 15 mmol/L glucose conditions, suggesting that  $\text{Ca}^{2+}$  is involved in SLIT induced downstream signaling.

**Conclusion:** Together, our results point to a possible context-dependent pro-survival role for SLIT-ROBO signaling in the adult pancreatic beta-cells. Since diabetes results from a deficiency in functional beta-cell mass, these studies could potentially contribute to the development of novel therapies to improve beta-cell survival.

### Effects of pancreatic stellate cell on islet amyloid deposition

J.M. Yin<sup>1,2</sup>, Z.L. Sun<sup>1,2</sup>, F.F. Li<sup>1,2</sup>, Q. Zhai<sup>1,2</sup>

<sup>1</sup>Department of Endocrinology, Zhongda Hospital, <sup>2</sup>Institute of Diabetes, Medical School, Southeast University, Nanjing, China.

**Background and aims:** Islet amyloid deposition is a pathological hallmark of type 2 diabetes, which mainly consists of islet amyloid polypeptide, also called amylin. However, its pathogenesis has not been fully understood. Activated pancreatic stellate cell (PSC) plays a vital role in pancreatic fibrosis and increasing evidences show that it also has additional effects on islets. Therefore, we intend to explore whether activated PSC could affect the expression of amylin.

**Materials and methods:** 1. To establish Ins-1/PSC co-culture system, PSCs were isolated from male Sprague-Dawley rats, Ins-1 cells were incubated in the media containing 5.5 or 16.7 mM glucose, cultured with or without activated PSCs. The supernatants of each group were collected for amylin concentration measurement by ELISA after 1, 2, and 6h. Ins-1 cells were harvested for amylin mRNA expression detection by Real Time-PCR after 6, 12, and 24h. 2. To establish islet/PSC co-culture system, islets and PSCs were isolated from male Sprague-Dawley rats, after overnight recovery, islets were transferred to culture media containing 5.5 or 16.7 mM glucose, cultured with or without activated PSCs. After 6, 12, and 24h, the supernatants of each group were collected for amylin concentration measurement by ELISA. Islets were harvested for amylin mRNA expression detection by Real Time-PCR and amylin protein content detection by ELISA.

**Results:** 1. At the end of each incubation period, the secretion and gene expression of amylin of Ins-1 cells cultured in the media containing 16.7 mM glucose markedly increased compared with those cultured in 5.5mM glucose ( $p<0.05$ ). The secretion of amylin increased by the presence of PSCs, whether cultured in 5.5 or 16.7 mM glucose ( $p<0.05$ ). The gene expression of amylin increased by the presence of PSCs when cultured in 16.7 mM glucose ( $p<0.05$ ). 2. At the end of each incubation period, the secretion of amylin of islets co-cultured with PSCs were significantly higher than those cultured without PSCs, whether treated with 16.7 mM glucose or 5.5mM glucose ( $p<0.05$ ). The amylin protein content and gene expression in the islets were in accordance with the secretion measurement ( $p<0.05$ ).

**Conclusions:** 1. PSC may promote the secretion of amylin in Ins-1 cells. 2. High glucose could promote the secretion and expression of amylin in Ins-1 cells, and PSC may enhance high glucose inducing amylin secretion and ex-

pression. 3. PSC may promote the secretion and expression of amylin in islets. 4. High glucose could promote the secretion and expression of amylin, and PSC may enhance high glucose inducing amylin secretion and expression.

### UCH-L1 deficiency in mice exacerbates human islet amyloid polypeptide toxicity in beta cells: evidence of cross-talk between the ubiquitin/proteasome system and autophagy

S. Costes, T. Gurlo, J.F. Rivera, P.C. Butler;

Larry Hillblom Islet Research Center, UCLA, Los Angeles, USA.

**Background and aims:** Type 2 diabetes (T2DM) is characterized by a deficit in beta-cell mass due to beta-cell apoptosis induced, at least in part, by the toxic forms of misfolded islet amyloid polypeptide (IAPP). We recently reported that increased expression of human-IAPP (h-IAPP) disrupts the ubiquitin/proteasome pathway in beta-cells of individuals with T2DM, as demonstrated by the accumulation of polyubiquitinated proteins associated with the deficiency in the deubiquitinating enzyme UCH-L1 (Ubiquitin C-terminal hydrolase-L1). Using h-IAPP transgenic rodent models, we also recently reported that expression of amyloidogenic h-IAPP in beta-cells compromises the second pathway of protein degradation known as autophagy. In this study, we used mouse genetics to elucidate the potential synergistic effect of UCH-L1 deficiency and excess of oligomerization prone h-IAPP in diabetes progression, and we further investigated whether UCH-L1 deficiency could exacerbate autophagy defects in this mouse model.

**Materials and methods:** Mice overexpressing h-IAPP in UCH-L1-deficient beta-cells (UCH-L1<sup>-/-</sup>, h-IAPP-Tg) were obtained by crossbreeding h-IAPP transgenic mice and the nm3419 mice harboring a deletion mutation in the *Uchl1* gene. Wild type, UCH-L1<sup>+/-</sup> and h-IAPP-Tg mice were used as controls. The study has been carried out along the "Principles of laboratory animal care" (NIH Publication no. 85-23, revised 1985) and according to the national law. UCH-L1 deletion was confirmed by genomic PCR, immunoblotting and measurement of UCH-L1 activity in isolated mouse islets. Fasting blood glucose and body weight were measured weekly starting from 5 weeks. Pancreases were collected from 7-8 week-old mice to evaluate islet morphology, beta-cell mass and beta-cell death (TUNEL) by immunofluorescence. Apoptosis in islets was also evaluated by measuring levels of cleaved caspase-3 by immunoblotting. Autophagy was assessed by immunoblotting and immunofluorescence for LC3-II, a marker of autophagosome number, and for p62, an ubiquitin-binding protein, which interacts with LC3-II, allowing lysosomal degradation of polyubiquitinated proteins and itself.

**Results:** UCH-L1<sup>-/-</sup>, h-IAPP-Tg mice became hyperglycemic at 7 weeks (average glycemia 139 mg/dL,  $p<0.05$  vs h-IAPP-Tg mice), and thereafter exhibited severe diabetes, while control groups remained normoglycemic. Beta-cell mass declined in UCH-L1<sup>-/-</sup>, h-IAPP-Tg mice, showing 61% reduction at 7 weeks of age ( $p<0.001$  vs h-IAPP-Tg mice), accompanied by remodeling of islet architecture and increased beta-cell apoptosis. Analysis of autophagy in UCH-L1<sup>-/-</sup>, h-IAPP-Tg mice revealed an increase in the number of autophagosomes (1.6 fold increase in LC3-II levels,  $p<0.01$  vs h-IAPP-Tg mice) and a major increase in the number and size of cytoplasmic inclusions positive for p62 and ubiquitin (28.8% of beta-cells positive for inclusions vs 3.51% in h-IAPP-Tg mice,  $p<0.001$ ).

**Conclusion:** These data suggest that UCH-L1 deficiency exacerbated h-IAPP-induced beta-cell death caused at least in part by the amplified altera-

tion of the lysosome-dependant degradation. This study reveals a previously unrecognized role for UCH-L1 in the regulation of autophagy in beta-cells exposed to misfolded h-IAPP.

## 539

### The role of chaperones in the ER stress response induced by human IAPP overexpression

L. Cadavez<sup>1,2</sup>, P. Casini<sup>1,2</sup>, M. Soty<sup>1,2</sup>, M. Visa<sup>1,2</sup>, R. Gasa<sup>1,2</sup>, V. Petegnief<sup>3</sup>, A. Novials<sup>1,2</sup>;

<sup>1</sup>Diabetes and Obesity Laboratory, IDIBAPS, Hospital Clinic, <sup>2</sup>Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM), <sup>3</sup>Department of Brain Ischemia and Neurodegeneration, CSIC, Barcelona, Spain.

**Background and aims:** Human islet amyloid polypeptide (hIAPP) has been found as a principal constituent of islet amyloid deposits. The process of hIAPP aggregation is also a common mechanism with neurodegenerative diseases in which proteins adopt non-native conformation. In many cases, misfolding is a natural consequence of protein biogenesis, but in T2D, it may contribute to  $\beta$ -cell apoptosis. In addition, accumulation of misfolding proteins perturbs the endoplasmic reticulum (ER) homeostasis activating the unfolded protein response (UPR). Molecular chaperones have been described to be important for regulation of ER signaling in response to ER stress, among others. The aim of the present work is to investigate the UPR in a cellular model of hIAPP overexpression.

**Materials and methods:** Rat pancreatic  $\beta$ -cell line INS1E was stably transfected with hIAPP plasmid (INS1E\_hIAPP cells) under the cytomegalovirus (CMV) promoter. To evaluate ER stress response, INS1E\_hIAPP cells were culture with pharmacological (0.5  $\mu$ M thapsigargin) and non-pharmacological (25 mM glucose and 400  $\mu$ M palmitic acid) ER stress inducers in a time-dependent manner. Liposome-mediated transient BiP/GRP78 overexpression was performed in INS1E\_hIAPP cells. To mimic the plausible protective role of endogenous chaperone BiP/GRP78 during ER stress, INS1E\_hIAPP cells were pre-treated with the chemical chaperone taurine-conjugated ursodeoxycholic acid (TUDCA). Gene expression and protein levels of ER stress markers (CHOP, ATF3 and spliced XBP1) and BiP/GRP78 were analysed by real-time RT-PCR and western blot respectively.

**Results:** INS1E\_hIAPP cells cultured at 11 mM glucose did not show changes in the ER stress markers compared to INS1E control cells. Both cells were exposed to 0.5  $\mu$ M thapsigargin, an inducer of ER stress, for 8h. Interestingly, the expression of ER stress genes was higher in INS1E\_hIAPP (CHOP 11.2-fold, ATF3 42.3-fold and spliced XBP 8.3-fold) over untreated cells ( $p < 0.001$ ) compared to INS1E cells (CHOP 5.9-fold, ATF3 18.5-fold and spliced XBP1 4-fold) over untreated cells ( $p < 0.001$ ). At 24h, thapsigargin-treated INS1E\_hIAPP cells showed an increase in CHOP and ATF3 protein levels in relation to INS1E cells. INS1E\_hIAPP cultured at 25 mM glucose did not show changes in gene expression compared to basal glucose (11 mM). The addition of 400  $\mu$ M palmitic acid to 25 mM glucose induced an increase of ATF3 and spliced XBP1 mRNA expression levels of 4.2-fold, and 3.5-fold, respectively compared to basal conditions. At 24h INS1E\_hIAPP showed an increase in BiP protein levels compared to INS1E cells. Overexpression of BiP in INS1E\_hIAPP cells cultured with high glucose and palmitic acid did not modify the expression profile of ER stress markers. However, cells exposed to high glucose and palmitic acid treated with 200  $\mu$ M of TUDCA, showed a small but statistically decrease of ATF3 and spliced XBP1 genes (13%,  $p < 0.05$  and 18%,  $p < 0.05$  respectively).

**Conclusion:** Overexpression of hIAPP is sensed by ER and triggers the activation of UPR and enhances chaperone expression. Thereby, TUDCA seems to ameliorate ER stress, suggesting that improving chaperone capacity can be important to the folding of hIAPP.

### Role of the $\beta$ -secretase BACE2 in the mechanism of hIAPP-induced beta cell dysfunction

G. Alcarraz-Vizán<sup>1,2</sup>, P. Casini<sup>1,2</sup>, L. Cadavez<sup>1,2</sup>, M. Visa<sup>1,2</sup>, J.M. Servitja<sup>1,2</sup>, A. Novials<sup>1,2</sup>;

<sup>1</sup>Diabetes & Obesity Laboratory, IDIBAPS, Hospital Clinic, <sup>2</sup>Spanish Biomedical Research Centre in Diabetes and Associated Metabolic Disorders (CIBERDEM), Barcelona, Spain.

**Background and aims:** BACE2 ( $\beta$ -site APP-cleaving enzyme 2) is a  $\beta$ -protease that has been found in the brain, where it plays a role in the development of Alzheimer's disease (AD). It has also been localized in the pancreas, although its biological function is not fully known. A recent report demonstrated that BACE2-KO mice showed improved control of glucose homeostasis. Moreover, amyloidogenic diseases, including AD and type 2 diabetes (T2D), have been reported to share the accumulation of abnormally folded and insoluble proteins within or around cells that interfere with cell function. In the case of T2D, amylin (IAPP) deposits have been shown to be a key feature of the disease, although the mechanism of IAPP aggregation is poorly understood. In this framework, we have found that human IAPP (hIAPP) overexpression specifically induced BACE2 upregulation, therefore the aim of the present study was to investigate the implication of the  $\beta$ -secretase BACE2 in the  $\beta$ -cell alterations induced by hIAPP overexpression.

**Materials and methods:** The rat pancreatic  $\beta$ -cell line INS1E was stably transfected with hIAPP under the control of CMV promoter (INS1E-hIAPP cells). BACE2 expression was downregulated in INS1E-hIAPP using siBACE2. A liposome-mediated transient BACE2 overexpression was performed in INS1E cells. The enzymatic activity of BACE2 was detected in protein extracts with a fluorometric  $\beta$ -secretase proteolytic activity assay. The ability to secrete insulin in response to glucose (GSIS), as well as insulin content, was quantified with an ELISA kit. Proliferation was analyzed by BrdU assay, and mitochondrial metabolism measured as ROS production.

**Results:** hIAPP-INS1E cells presented a 4.5-fold increase of BACE2 expression with respect to INS1E cells ( $p < 0.05$ ). This increase was not observed in INS1E cells overexpressing rat IAPP. Insulin secretory response to glucose was 30% lower in hIAPP-INS1E cells than in INS1E cells ( $p < 0.05$ ). INS1E cells transfected with a transient overexpression of BACE2 showed a 1.3-fold increase in BACE2 activity ( $p < 0.05$ ). These cells presented a 3-fold increase in ROS production ( $p < 0.05$ ), as well as a 40% decrease in proliferation ( $p < 0.05$ ). Insulin secretory response to glucose in INS1E cells overexpressing BACE2 was 25% lower ( $p < 0.05$ ) than in control cells. When endogenous BACE2 was silenced in hIAPP-INS1E cells, there was a significant improvement in GSIS (3-fold increase in insulin secretory response stimulated by glucose with respect to hIAPP-INS1E cells,  $p < 0.05$ ), indicating the significant effect of BACE2 expression on  $\beta$ -cell function.

**Conclusion:** BACE2 levels are increased in  $\beta$ -cell dysfunction induced by hIAPP overexpression, and its downregulation improves insulin secretory response in rat pancreatic  $\beta$ -cells.

### Fibroblast growth factor-21 (FGF-21) synergizes with insulin in human adipose stem cell-derived (hASC) adipocytes

M.B. Brenner, D.V. Lee, B. Bernardo, S. Talukdar;  
CVMED, Pfizer, Cambridge, USA.

Over the past years FGF21, a member of the FGF19 subfamily, has evolved as a major metabolic regulator with beneficial effects on insulin sensitivity and glucose tolerance in rodents and other species. So far, in-vitro studies studying the effects of FGF-21 on insulin sensitivity have mostly been limited to observations in rodent cells after chronic treatment with FGF-21. Our study focuses on the acute effects of FGF-21 on insulin signaling using a human model of adipocytes, with the aim of providing insights on the crosstalk between FGF-21 and insulin signaling. Human adipose stem cell-derived (hASC) adipocytes were acutely treated with FGF-21 alone, insulin alone, or in combination. Insulin signaling under these conditions was characterized by measuring [<sup>14</sup>C]-2DG uptake, tyrosine phosphorylation of insulin receptor (InsR), insulin receptor substrate-1 (IRS-1), and serine 473 phosphorylation of Akt. FGF-21 alone caused a modest increase of glucose uptake, but acute treatment of FGF-21 in combination with insulin had a synergistic effect on glucose uptake in hASC-adipocytes. The presence of FGF-21 also effectively lowered the insulin concentration required to achieve the same level of glucose uptake as in the absence of FGF-21 by 10-fold. This acute effect of FGF-21 on insulin signaling was not due to InsR, IGF-1R, or IRS-1 activation. We do observe a substantial increase in basal S473-Akt phosphorylation by FGF-21 alone, in contrast to the minimal shift in basal glucose uptake. We conclude that acute co-treatment of hASC-adipocytes with FGF-21 and insulin synergistically improves maximal glucose uptake, and the mechanism of action lies downstream of Akt or outside the canonical insulin signaling pathway.

### IRS (insulin receptor substrate) -2 protein stability is increased by PKA-dependent 14-3-3 binding

S.S. Neukamm<sup>1,2</sup>, J. Ott<sup>3</sup>, S. Dammeier<sup>3</sup>, R. Lehmann<sup>1,2</sup>, H.-U. Haering<sup>1,2</sup>, E.D. Schleicher<sup>1,2</sup>, C. Weigert<sup>1,2</sup>;

<sup>1</sup>Internal Medicine IV, Division of Endocrinology, Diabetology, Vascular Medicine, Nephrology and Clinical Chemistry, University Hospital Tuebingen, <sup>2</sup>Paul Langerhans Institute, Member of the German Diabetes Centre, Institute for Diabetes Research and Metabolic Diseases of the Helmholtz Centre Munich at the University of Tuebingen, <sup>3</sup>Institute for Ophthalmic Research, University of Tuebingen, Germany.

**Background and aims:** IRS-1 and -2 as intermediate docking platforms transduce the insulin/IGF-1 signal to intracellular effector molecules that regulate glucose and lipid metabolism. Binding of 14-3-3 proteins can modify the activity of the binding partner, influence trafficking or obscure other nearby motifs for other interaction partners. 14-3-3 proteins bind their target protein via phosphorylated serine/threonine residues located within distinct motifs. Additionally, IRS-2 is regulated on the mRNA and protein level. Insulin suppresses IRS-2 mRNA expression, whereas glucagon promotes IRS-2 mRNA expression. Here we studied the regulated binding of 14-3-3 to IRS-2 upon PKA (protein kinase A) activation, determined the residues that mediate this interaction and the physiological consequences thereof.

**Materials and methods:** Fragments spanning different regions of the IRS-2 molecule and mass spectrometry were used to narrow down the 14-3-3 binding region on IRS-2 and potential PKA phosphorylation sites herein. Loss of function mutants and GST (glutathion S-transferase) and co-immunoprecipitation assays were applied to confirm the responsible residues for PKA-dependent 14-3-3 binding. Flp-In HEK293 cells stably expressing IRS-2 and primary hepatocytes were employed to investigate the potential biological importance of this interaction.

**Results:** Activation of PKA by forskolin increased 14-3-3 binding to IRS-2, whereas inhibition of PKA activity by the compound H89 blocked 14-3-3 binding to IRS-2 in transiently transfected HEK293 and rat hepatoma (Fao) cells. The area behind amino acid 952 on IRS-2 could be identified as 14-3-3 binding region and mass spectrometric analyses revealed serine 1137 and serine 1138 as potential PKA phosphorylation sites. This was tested by application of an antibody that recognizes potential PKA phosphorylation sites.

GST pulldown and co-immunoprecipitation assays confirmed serine 1137 and serine 1138 to be part of 14-3-3 binding to IRS-2. Flp-In HEK293 cells stably expressing IRS-2 showed a reduction in IRS-2 content of 90 % ± 3 % (n=8) after 3 and 6 hours of cycloheximide treatment. Contrary, cells that were treated in combination with forskolin showed only a reduction in IRS-2 protein content of about 30 % ± 10 % (n=8) after 3 and 6 hours of treatment, thus IRS-2 protein showed increased stability.

**Conclusion:** We present a novel regulatory mechanism of IRS-2 protein stability - the PKA-dependent 14-3-3 binding to IRS-2.

### Knockdown of PRAS40 promotes proteasomal degradation of IRS1 and insulin resistance in human skeletal muscle cells

C. Wiza, D. Herzfeld de Wiza, S. Lehr, D.M. Ouwens;

Institute of Clinical Biochemistry and Pathobiochemistry, German Diabetes Center, Duesseldorf, Germany.

**Background and aims:** Insulin resistance is a hallmark of type 2 diabetes and characterized by alterations in Akt- and mammalian target of rapamycin complex 1 (mTORC1) signaling. In rodent models of insulin resistance, hyperactivation of the mTORC1/p70S6K-axis is linked to inhibition or even degradation of the insulin receptor substrate 1 (IRS1). The proline-rich Akt substrate of 40kDa (PRAS40) is a component of the mammalian target of rapamycin-complex 1 (mTORC1) and one the most prominent Akt substrates in skeletal muscle. Studies in cultured cell lines ascribed both inhibitory and stimulatory roles to PRAS40 in the regulation of mTORC1 activity and insulin action. Genetic evidence from *Drosophila* indicated that the regulation of mTORC1 activity is tissue-specific and dependent on post-translational modification of PRAS40. This study aimed to detail the function of PRAS40 in insulin action in primary human skeletal muscle cells (hSkMC) under normal conditions and following monocyte chemo-attractant protein 1 (MCP1) induced insulin resistance.

**Materials and methods:** Primary hSkMC from different donors were differentiated *in vitro* for 7 days. On day 3 of differentiation, cells were transfected with either a non-target siRNA or specific PRAS40-siRNAs. On day 6 of differentiation, myocytes were incubated with 2 ng/ml MCP1 (24h) prior to stimulation with 100 nM insulin for 10 min. For inhibition of the proteasome, PRAS40 knockdown (PRAS40 KD) and control cells were treated with 3 μM MG-132 for 24h. Alterations in the phosphorylation and protein expression of targets of Akt- and mTORC1 signaling were analyzed by Western blotting, real-time PCR or bead-based multiplex assays.

**Results:** Knockdown of PRAS40 in hSkMC decreases insulin-mediated phosphorylation of Akt by 50% ( $P<0.05$ ) and abrogated insulin action downstream of Akt, as illustrated by diminished insulin-stimulated phosphorylations of glycogen synthase kinase 3 (40%) and tuberous sclerosis complex 2 (32%) (both  $P<0.05$ ). Furthermore, in the absence of changes in Glut4 protein expression, insulin-stimulated glucose uptake was reduced by 20% in PRAS40KD versus non-target myocytes ( $P<0.05$ ). Finally, PRAS40-KD affected mTORC1 signaling as illustrated by inhibition of insulin-mediated phosphorylation of mTOR (30%), and its substrates p70S6K (47%) and 4E-BP1 (30%), as well as by reducing the protein expression of the newly identified mTORC1 target growth factor receptor bound protein 10 (Grb10) (35%) (all  $P<0.05$ ). Comparable results were obtained with two distinct PRAS40-siRNAs in cells from different donors. Exposing PRAS40KD-myocytes to MCP1 caused no further deterioration of insulin action. The abrogation of insulin action by PRAS40KD and MCP1 could be ascribed to a proteasome-mediated reduction in IRS1 protein levels (60% reduction after PRAS40KD and 55% after MCP1 treatment) (both  $P<0.05$ ). Accordingly, pharmacological inhibition of the proteasome by MG-132 restored IRS1-abundance and insulin sensitivity induced by both PRAS40 KD and MCP1.

**Conclusion:** Collectively, this study identifies PRAS40 as a modulator of insulin action in primary human skeletal muscle cells. In these cells, the absence of PRAS40 abrogates insulin action by promoting the proteasome-mediated degradation of IRS1 rather than by hyperactivation of the mTOR-p70S6K/Grb10 negative feedback loop.

### Analysis of signalling pathways stimulated by insulin, AspB10, insulin glargine and its metabolites in human colon cancer cell lines

J. Raschert, S. Welte, G. Tschanke, N. Tennagels;

Sanofi, Frankfurt, Germany.

**Background and aims:** Insulin glargine (GLA) is a long-acting insulin analogue that, in contrast to X10, did not show an increased incidence of mammary tumours in rats and mice in 2-year carcinogenicity studies. *In vivo*, GLA is rapidly and significantly metabolised into metabolite M1 that has a metabolic profile like GLA but a mitogenic profile identical to human insulin (HI). Our aim was to compare the mitogenic activity and signalling behaviour of GLA and M1 with IGF-1, HI and X10 in human colon cancer cell lines that

have different IGF-1 receptor (IGF1R)/insulin receptor (IR) and IR-A/IR-B ratios.

**Materials and methods:** The stimulation of IR and IGFR autophosphorylation and AKT and ERK1/2 phosphorylation as well as thymidine incorporation by HI and insulin analogues was investigated in the human colon cancer cell lines HCT116, DLD1, HT29, SW480, Colo205 and LoVo.

**Results:** X10 was the most potent stimulator of IR and IGFR autophosphorylation and AKT phosphorylation in all cell lines studied. No differences were observed between the signalling behaviour of M1 and HI in any of the cell lines. GLA displayed IR activity comparable with HI in all cell lines studied. IGFR phosphorylation was also comparable, except for an increase in HT29 and Colo205 cells compared with 50 nM HI (GLA: 1.7- and 1.5-fold; IGF-1: 5.1- and 3.2-fold), that was also reflected in decreased EC50 values for AKT phosphorylation in the 2 cell lines (GLA: 4- and 1.7-fold; IGF-1: 4- and 19-fold, respectively). ERK1/2 phosphorylation and radioactive thymidine incorporation were unaffected by insulin or analogue treatment in all cell lines. However, poly (ADP-ribose) polymerase (PARP) cleavage was significantly decreased, reflecting an anti-apoptotic response, in HCT116 cells exposed to X10 and IGF1 but not GLA or M1.

**Conclusion:** The data indicate that *in vitro* M1 displays an IR- and IGFR-mediated profile comparable with HI for all colon cancer cell lines investigated. GLA was also comparable to HI, except for an increase in IGFR and AKT phosphorylation in 2 cell lines. This emphasises the importance of studying the multiple steps in the action of an insulin analogue and its metabolites *in vitro* and *in vivo*.

### Insulin affects tyrosine hydroxylase expression in neuronal PC12 cells through Hif-1alpha activation

F. Fiory<sup>1</sup>, P. Mirra<sup>1</sup>, C. Nigro<sup>1</sup>, L. Ulianich<sup>1</sup>, M. Lucariello<sup>1</sup>, F. Zatterale<sup>1</sup>, A. Leone<sup>1</sup>, P. Formisano<sup>2</sup>, F. Beguinot<sup>1,2</sup>, C. Miele<sup>1</sup>;

<sup>1</sup>IEOS, CNR, <sup>2</sup>University Federico II, Naples, Italy.

**Background and aims:** Dopamine plays a key role in regulating behavior and cognition, sleep, mood and learning. Dysfunctions of the dopamine system lead to neurodegenerative disease such as Parkinson's disease, an age-related degenerative condition causing tremor and motor impairment. It has been recently shown that streptozotocin-diabetic rats have lower catecholamines levels in the corpus striatum and immunoreactive tyrosine hydroxylase (TH), the rate limiting enzyme in catecholamines synthesis, is decreased in nigrostriatal neurons of the genetically diabetic BB Wistar rats. Recent studies show that diabetes represents a risk factor for dementia and is associated to an increased risk of Parkinson's disease. Moreover, impairment of insulin synthesis or action is associated with neurodegenerative diseases and with a decline in cognitive function.

**Materials and methods:** TH protein and mRNA levels in PC12 cells were evaluated by Western blot and RT-PCR respectively. Chlp experiments and luciferase assays were performed to evaluate Hif-1alpha role in regulating TH expression in response to insulin.

**Results:** We have evaluated insulin ability to regulate TH levels in PC12 cells. TH mRNA levels are increased by 50% upon 1-2 h of 100 nM insulin treatment and return to basal values after 6-8 h of insulin stimulation. Prolonged incubation (16-24h) of PC12 cells with insulin induces a further gradual increase in TH mRNA expression. By contrast, TH protein levels are increased after 1 hour of insulin stimulation and are still elevated upon 24h of insulin treatment. Pharmacological inhibition of the transcription factor Hif-1alpha, a known regulator of TH expression, almost completely abolishes insulin positive effect on TH mRNA. Moreover, insulin stimulation increases the binding of Hif-1alpha and of its cofactor p300 to TH promoter and induces the reporter gene activity of a TH promoter-luciferase construct in HeLa cells. This effect is lost when cells are transfected with a dominant negative of Hif-1alpha or with a vector containing the mutagenized Hif-1alpha binding sequence.

**Conclusion:** These results suggest that insulin regulates TH mRNA expression by activating Hif-1alpha. Improvement of insulin signal transduction in brain could preserve neurotransmitters content in diabetic condition.

## 546

**Impact of exogenous follistatin on primary human myotubes**P. Plomgaard<sup>1,2</sup>, B.K. Pedersen<sup>1</sup>, P.A. Halban<sup>3</sup>, K. Bouzakri<sup>3</sup><sup>1</sup>Centre of Inflammation and Metabolism, Rigshospitalet, Copenhagen, Denmark, <sup>2</sup>Department of Clinical Biochemistry, Rigshospitalet, Copenhagen, Denmark, <sup>3</sup>Department of Genetic Medicine and Development, Medical Centre, Geneva University, Switzerland.

**Background and aims:** Follistatin is a protein found in the circulation. It has recently been demonstrated that plasma follistatin increases rapidly after an acute bout of exercise. This finding indicates a new role for follistatin, which so far mainly has been investigated in reproduction physiology. Follistatin antagonises and neutralises several members of the TGF- $\beta$  family in the circulation. Of particular interest in relation to exercise is myostatin or GDF-8. Myostatin is produced and secreted by the skeletal muscle, where it suppresses growth and hypertrophy, and is believed to be neutralised in the circulation by follistatin. Here we investigate the effect of exogenous follistatin on human skeletal muscle cells.

**Materials and methods:** Recombinant human follistatin was used to treat human primary myotubes. Myoblasts were isolated from human abdominal skeletal muscle. These were grown into confluence and differentiated for 5 days with and without 50 ng/ml recombinant human follistatin. mRNA was measured by qRT-PCR. Glucose uptake was measured by incorporation (10 min) of 3H-2-deoxyglucose.

**Results:** Human primary myotubes differentiated in the presence of human recombinant follistatin resulted in a hypertrophic myotube when compared to the non-treated condition. mRNA was isolated from the differentiated myotubes and a higher level of MEF2A (1.6  $\pm$  0.14 fold,  $P < 0.05$ ) and MEF2C (3.8  $\pm$  1.2 fold,  $P < 0.05$ ) was found in the follistatin differentiated myotubes. Differentiation with follistatin suppressed MEF2D mRNA 1.9 fold ( $P < 0.05$ ). Interestingly GLUT1 mRNA was suppressed 1.4 fold ( $P < 0.05$ ) whereas GLUT4 was increased 1.6 fold ( $P < 0.05$ ), after differentiation with follistatin. Because follistatin changed the expression of the glucose transporters, glucose uptake was measured with 0, 10 and 100 nM insulin. Without insulin a 1.7 fold reduction in glucose uptake was observed after differentiation with follistatin. A low dose of insulin (10 nM) elicited a 1.4 fold ( $P < 0.05$ ) increase in glucose uptake only in the follistatin treated but not control myotubes, whereas at 100 nM insulin similar absolute levels of glucose uptake were seen.

**Conclusion:** These data indicate that increased exogenous follistatin during muscle differentiation results in a more insulin sensitive cellular phenotype. Furthermore, as models of follistatin over-expression within skeletal muscle have also demonstrated, exogenous follistatin can induce skeletal muscle cell hypertrophy. Taken together these data suggest that exogenous follistatin has a beneficial impact on the skeletal muscle and support the idea that follistatin could have a therapeutic potential.

## 547

**LY2881835: a potent, efficacious and selective GPR40 agonist stimulates insulin and GLP-1 secretion normalising glucose levels in preclinical models of type 2 diabetes**A. Reifel Miller<sup>1</sup>, A. Cox<sup>1</sup>, D. Briere<sup>1</sup>, M. Marcelo<sup>1</sup>, S. Rani S.N.<sup>2</sup>, R. Padmaja.<sup>2</sup>, K. Wilbur<sup>1</sup>, E. Osborne<sup>1</sup>, R. Zink<sup>1</sup>, D. Jett<sup>1</sup>, C. Montrose-Rafizadeh<sup>1</sup>, M. Michael<sup>1</sup>, K. Bokvist<sup>1</sup>, P. Matti<sup>2</sup>, C. Hamdouch<sup>1</sup><sup>1</sup>Endocrinology, Lilly Research Laboratories, Indianapolis, USA, <sup>2</sup>Jubilant BioSys Ltd, Bangalore, India.

**Background and aims:** GPR40, also known as free fatty acid receptor 1 (FFAR1), is located primarily on endocrine cells of the pancreas and in the gastrointestinal (GI) tract. Engagement of GPR40 by native and synthetic ligands activates the G-protein heterotrimer G $\alpha$ q/11 resulting in elevated intracellular calcium levels. In pancreatic islet beta cells, activation of this pathway results in glucose-dependent insulin secretion (GDIS). Thus, an orally available synthetic GPR40 agonist would be expected to lower glucose levels only in the setting of hyperglycemia, potentially providing an efficacious therapeutic approach for the treatment of type 2 diabetes (T2D) that avoids hypoglycemia.

**Materials and methods:** LY2881835 is a novel spiro[indene-1,4'-peperidine] identified via a medium throughput screen followed by rationale design optimization. This molecule was characterized in-vitro for GPR40 activity and selectivity plus in-vivo as a potential therapeutic option for T2D.

**Results:** LY2881835 is a potent (233nM) and efficacious (92%) GPR40 full agonist when compared with the native ligand, linoleic acid, in a calcium flux assay (FLIPR) assay using a recombinant hGPR40/HEK293 cell line. This member of a new structural class of GPR40 agonists demonstrates selectivity against PPARs and stimulates glucose dependent insulin secretion (GDIS) in the mouse insulinoma cell line Min6, and in primary islets from mice, rats and humans. When administered orally at 3 mg/kg to Sprague Dawley rats 60 minutes prior to the start of a hyperglycemic (250 mg/dl) clamp, LY2881835 produced an immediate and prolonged increase in insulin secretion and required a significant elevation (3-fold) in the glucose infusion rate thus confirming in-vivo target engagement and activation of GPR40. After four days of oral administration of LY2881835 to normal mice, potent dose dependent reductions in glucose levels ( $ED_{50} = 0.58$  mg/kg) along with significant increases in insulin secretion were seen during an ipGTT. When chronically administered to Zucker fa/fa rats, glucose levels during an OGTT were dose dependently lowered with similar  $ED_{50}$ s on days 1 and 21 indicating that desensitization of the receptor did not occur after chronic activation. Cell-based and in-vivo studies were performed to explore the ability of LY2881835 to activate GPR40 in the GI tract. An immediate and prolonged increase in GLP-1 secretion was seen when LY2881835 was administered orally to normal mice at 30 mg/kg, plus a dose dependent increase in GLP-1 secretion was seen in the mouse gut tumor cell line, STC-1.

**Conclusion:** Synthetic, orally available GPR40 agonists that simulate GDIS plus GLP-1 secretion make excellent clinical candidates for the early and aggressive treatment of T2D without the liability of hypoglycemia

## 548

**Different acetylation patterns determine the translocation behaviour of FOXO1**M.A. Osterhoff<sup>1,2</sup>, C. Bumke-Vogt<sup>2,1</sup>, S. Schiess<sup>2</sup>, V. Baehr<sup>1</sup>, D. Schmoll<sup>3</sup>, A.F.H. Pfeiffer<sup>1,2</sup><sup>1</sup>Endocrinology, Diabetes and Nutrition, Charité - University Medicine Berlin, CBF, Berlin, <sup>2</sup>Clinical Nutrition, German Institute of Human Nutrition, Potsdam-Rehbruecke, Nuthetal, <sup>3</sup>Sanofi-Aventis Germany GmbH, Frankfurt am Main, Germany.

**Background and aims:** FOXO1 is a transcription factor ubiquitously expressed in human cells which facilitates different tasks like metabolic and energy homeostasis, development, and protection to cellular stress. The proper and specific function of FOXO is mediated by a set of post-translational modifications like phosphorylation, acetylation, ubiquitinylation, and sumoylation. While it is well known that phosphorylation at ser256 is the gate-keeper for the dissociation of FOXO from DNA and, thus, for its inactivation, there is only insufficient knowledge of the function of different acetylation patterns. The aim of this study is to investigate the function of these acetylation patterns on FOXO activity and localization.

**Materials and methods:** A FOXO translocation assay has been established using FOXO1 with a C-terminal GFP-tag which is constitutively expressed in stably transfected U-2OS (human osteosarcoma cell line) or transiently transfected into HepG2 (human hepatoma) cells and detected by fluorescent microscopy in real-time. Site directed mutagenesis was used to create different constructs where lysine is mutated to arginine to mimic de-acetylated sites. Nuclear exclusion was initiated by use of 100 nmol/L insulin, nuclear import by use of 50  $\mu$ mol/L resveratrol or luteolin.

**Results:** While the nuclear exclusion of w.t. FOXO1-GFP with 100 nmol/L insulin was accomplished in approx. 10 min, a construct where lysine 245, 248 and 265 were mutated to arginine needed nearly 30 min for nuclear export under the same conditions. Interestingly, a construct where lysine 245 and 265 were mutated to arginine translocated more slowly into the cytosol compared to the w.t. FOXO1-GFP and accumulated in a peri-nuclear manner. The w.t. and mutated constructs stably re-translocated into the nucleus with resveratrol or luteolin. Mutation of lysine 274 and 294 resulted in nuclear exclusion of FOXO1-GFP after administration of 100 nmol/L insulin in a similar time-course as the w.t. FOXO1-GFP. Luteolin caused a nuclear re-import of the K274R/K294R construct but in contrast to the constructs tested before this one re-translocated into the cytosol after 20 min without adding any additional stimulus.

**Conclusion:** The experiments support the hypothesis that acetylation of FOXO1 facilitates an easier phosphorylation of FOXO1 leading to a faster dissociation of FOXO1 from DNA and faster nuclear exclusion. Constructs where several acetylation sites were mutated showed a delayed translocation. Acetylation patterns also seem to define the subcellular localization of

FOXO1. Therefore, analysis of FOXO1-acetylation pattern might be a valuable tool to determine FOXO1 function and the metabolic state of a cell.

### Cyclosporin A and tacrolimus can reduce GLUT4 at the cell surface via increased endocytosis and this leads to impaired cellular glucose uptake

M.J. Pereira<sup>1,2</sup>, J. Palming<sup>1</sup>, M. Rizell<sup>3</sup>, M. Aureliano<sup>2</sup>, E. Carvalho<sup>4</sup>, M.K. Svensson<sup>5</sup>, J.W. Eriksson<sup>1,6</sup>

<sup>1</sup>The Lundberg Laboratory for Diabetes Research, Department of Molecular and Clinical Medicine, Sahlgrenska Academy at University of Gothenburg, Sweden, <sup>2</sup>Center for Marine Sciences (CCMar), DCBB/FCT, University of Algarve, Faro, Portugal, <sup>3</sup>Department of Surgery, Sahlgrenska Academy at University of Gothenburg, Sweden, <sup>4</sup>Center of Neuroscience and Cell Biology, University of Coimbra, Portugal, <sup>5</sup>Department of Molecular and Clinical Medicine, Sahlgrenska University Hospital, Gothenburg, Sweden, <sup>6</sup>AstraZeneca R&D, Mölndal, Sweden.

**Background and aims:** The immunosuppressive agents (IA), cyclosporine (CsA) and tacrolimus (FK), are both calcineurin inhibitors and they are associated with several side effects including hyperglycaemia and new-onset diabetes after organ transplantation. We investigated the direct effects of therapeutic concentrations of CsA and FK on glucose uptake and insulin signalling in human adipocytes and on regulation of cellular trafficking of the glucose transporter GLUT4.

**Materials and methods:** Glucose uptake and protein expression of insulin signalling proteins were measured in isolated subcutaneous adipocytes, obtained from 42 healthy volunteers, incubated in the absence and presence of CsA or FK and insulin (1000 µU/mL). Effects of IA on cellular distribution of GLUT4 in human preadipocytes differentiated into adipocytes, was evaluated by immunohistochemistry and confocal microscopy. In addition, effects of IA on endocytotic and exocytotic rates of the transporter were studied in L6 myoblasts stably expressing GLUT4 with an exofacially directed Myc-tag by an enzyme-linked immunosorbent-like assay.

**Results:** CsA and FK both had a concentration dependent inhibitory effect on basal and insulin-stimulated <sup>14</sup>C-glucose uptake in adipocytes (1nM-1µM: ~10 to 40%, p<0.05). Although the phosphorylation of IR at Tyr1146 was inhibited by CsA and FK, phosphorylation and/or protein levels of proximal insulin signalling proteins (IRS1/2, p85-PI3K, PKB, AS160, mTOR1C) and GLUT1 and 4 content were not changed upon incubation of adipocytes with IA. Furthermore, incubation of differentiated human adipocytes with CsA or FK led to a reduction of GLUT4 localized at the cell surface (by 50–80%, p<0.05). In addition, CsA and FK similarly reduced the cell surface levels of GLUT4 in L6 muscle cells, by ~20% (p<0.05), and increased the GLUT4 endocytosis rate, by up to 30% (p<0.05), with no change in exocytosis rate.

**Conclusion:** In conclusion, these results suggest that therapeutic concentrations of cyclosporin A and tacrolimus, inhibit glucose uptake by removing GLUT4 from the cell surface via increased endocytosis and this is independent of the insulin signalling cascade. It is believed that the described effects of immunosuppressive agents on adipocytes and other insulin-sensitive cells may contribute to the development of insulin resistance and new-onset diabetes associated with immunosuppressive therapy in organ-transplanted patients, particularly in regard to those known as calcineurin inhibitors.

### Flavonoids like apigenin and luteolin induce FOXO1 translocation and differential gene expression patterns in human cells

C. Bumke-Vogt<sup>1,2</sup>, M.A. Osterhoff<sup>2,1</sup>, V. Guzman-Perez<sup>1</sup>, S. Schiess<sup>1</sup>, A. Borchert<sup>1</sup>, V. Baehr<sup>2</sup>, A.F.H. Pfeiffer<sup>2,1</sup>

<sup>1</sup>Clinical Nutrition, German Institute of Human Nutrition, Potsdam-Rehbrücke, Nuthetal, <sup>2</sup>Endocrinology, Diabetes and Nutrition, Charité – University Medicine Berlin, Germany.

**Background and aims:** Modulation of insulin signalling by nutritional components is a feasible method to prevent insulin resistance, increase of gluconeogenesis and the development of type 2 diabetes. We screened micronutrients by analyses of FOXO1 translocation as a mediator of insulin effects. To this end we established a stably transfected human cell line (U-2OS-FOXO1-

GFP) with constitutive expression of FOXO1 with a C-terminal GFP-tag for fluorescent-microscopic detection. Micronutrients with potential FOXO1 translocation activity were further analysed for modulating expression of FOXO1 target genes in human hepatoma cells (HepG2) which express gluconeogenic, antioxidative, and cell cycle modulating genes.

**Materials and methods:** Cell cultures of U-2OS-FOXO1-GFP were treated with natural compounds of plant extracts for 2h in a range of 1 to 100µmol/L. Cells were fixed and stained with DAPI for defining nuclear areas during fluorescence microscopy followed by segmentations of cells for intracellular FOXO1-GFP localization. FOXO1 translocation was determined by calculating the ratio of GFP intensities in nuclear and cytoplasmic areas. Reversibility of FOXO1 nuclear translocation was examined in the presence of insulin 100nmol/L. Additionally intracellular trafficking of FOXO1 was visualized using live cell imaging. Gene expression profiling was performed with HepG2 cells. Following starvation cells were treated with 0.5 to 100µmol/L of apigenin and luteolin for 2h and 24h, respectively. RNA was extracted and gene expression determined by qRT-PCR for phosphoenolpyruvatecarboxykinase (PEPCK), glucose-6-phosphatase (G6Pase), catalase (CAT), superoxide-dismutase (SOD), cyclinG2 (CCNG2), cyclin dependent kinase inhibitors 1A/B (p21CIP/p27KIP), and GADD45 for growth arrest and DNA damage repair.

**Results:** Apigenin induced a significant dose dependent nuclear translocation of FOXO1 within the range of 2 to 100µmol/L while the induction by luteolin was already significant from 1 to 100µmol/L. This nuclear import of FOXO1 was reversed by stimulating cells with insulin 100nmol/L. Despite FOXO1 accumulation in the nuclei by apigenin and luteolin, a dose dependent decrease of mRNA expression after 24h was obtained for PEPCK (being significant for apigenin A ≥ 10µmol/L, luteolin L ≥ 20µmol/L), G6Pase (A ≥ 10µmol/L, L ≥ 20µmol/L), CAT (A ≥ 10µmol/L, L ≥ 20µmol/L), SOD (A ≥ 10µmol/L, L ≥ 20µmol/L), CCNG2 (A ≥ 10µmol/L, L ≥ 30µmol/L), p27KIP (A ≥ 20µmol/L, L ≥ 25µmol/L), whereas p21CIP and GADD45 were induced with apigenin 10µmol/L and luteolin 20µmol/L. After 2h treatment with flavonoids downregulation was less pronounced for PEPCK, CyclinG2 and p27KIP. CAT and SOD were not modulated and an upregulation of p21CIP and GADD45 was not detectable in short term expression.

**Conclusion:** Apigenin and luteolin induce an intranuclear accumulation of the transcription factor FOXO1. The FOXO1 targets p21CIP leading to G1 arrest and GADD45 inducing G2 delay and DNA-repair are upregulated by both flavonoids facilitating antiproliferative effects. In contrast, FOXO1 targets like PEPCK and G6Pase responsible for gluconeogenesis are downregulated by apigenin and luteolin with a potential antidiabetic effect.

### Transgenic overexpression of Nrf2 ameliorates oxidative stress and several components of the metabolic syndrome in the spontaneously hypertensive rats

O. Oliyarnyk<sup>1</sup>, H. Malinska<sup>1</sup>, L. Kazdova<sup>1</sup>, M. Pravenec<sup>2</sup>;<sup>1</sup>Department of Metabolism and Diabetes, IKEM, <sup>2</sup>Institute of Physiology, Academy of Sciences, Prague, Czech Republic.

**Background and aims:** Nuclear factor-erythroid 2-related factor-2 (*Nrf2* or *Nfe2l2*) is a key transcription factor responsible for constitutive and inducible expression of ARE (antioxidant response element)-regulated genes of antioxidant enzymes. To test the role of this transcription factor in the pathogenesis of metabolic disturbances associated with metabolic syndrome, we investigated the effect of *Nrf2* transgenic expression in spontaneously hypertensive rats (SHR) on the activity of antioxidant enzymes in liver, myocardium, aorta and renal cortex, lipid peroxidation, and carbohydrate and lipid metabolism. **Materials and methods:** Transgenic line of SHR rats was derived by microinjecting zygotes with the mix of the Sleeping Beauty (SB) construct containing *Nfe2l2* cDNA under control of the CAGGS universal promoter and the SB100X transposase. Activity of antioxidant enzymes was measured using kits of Cayman Chemicals, MI, USA.

**Results:** The *Nrf2* transgene was significantly expressed in multiple tissues which was associated with tissue-specific activation of antioxidant enzymes. Compared to SHR controls superoxide dismutase (SOD) activity was elevated in renal cortex (0.060±0.004 vs. 0.039±0.003 U/mg protein, *p*<0.01). Glutathione peroxidase (GSH-Px) activity was increased in plasma, liver, myocardium and aorta (Table), glutathione transferase (GST) was activated in all investigated tissues. Glutathione (GSH) concentration was increased in plasma (6.55±0.18 vs. 5.53±0.19 μM/ml, *p*<0.01) and renal cortex (15.9±0.9 vs. 11.7±1.4 mM/mg, *p*<0.05). Lipid peroxidation products-thiobarbituric acid reactive substances were significantly reduced compared to SHR controls in plasma (1.070±0.101 vs. 1.701±0.110 nM/mg, *p*<0.001), liver (0.96±0.10 vs. 1.64±0.17 nM/mg, *p*<0.05), aorta (0.471±0.035 vs. 0.632±0.060 nM/mg, *p*<0.05) and renal cortex (0.55±0.04 vs. 0.69±0.05 nmol/mg, *p*<0.05). Transgenic rats exhibited increased basal (19.9±2.3 vs. 36.3±4.4 nmol gl./mg prot./2h, *p*<0.01) and insulin stimulated lipogenesis (90±17 vs. 43±6 nmol gl./mg prot./2h, *p*<0.05) measured as incorporation of <sup>14</sup>C-U- glucose into epididymal fat triglycerides and adrenalin stimulated lipolysis (5.2±0.7 vs. 3.2±0.6 μM/g NEFA, *p*<0.05) which suggests higher metabolic activity of adipose tissue. In addition, insulin stimulated incorporation of glucose into diaphragm glycogen was significantly increased (313±48 vs. 151±35 nM gl./g/2h, *p*<0.05) in transgenic rats.

**Conclusion:** Results indicate that *Nrf2* transgenic expression in SHR rats ameliorate oxidative stress in plasma, liver, myocardium, aorta and kidney and improved some features of the metabolic syndrome. Given the role of *Nrf2* as a regulator of antioxidant system, insulin sensitivity and lipid homeostasis, the pharmacological manipulation of *Nrf2* might be beneficial in treatment metabolic disorders related to insulin resistance.

### Insulin-receptor substrate-2 (IRS-2) is necessary to maintain the glucokinase and glucokinase regulatory protein expression in mouse liver

E. Blazquez<sup>1,2</sup>, I. Roncero<sup>1,2</sup>, E. Alvarez<sup>1,2</sup>, C. Acosta<sup>3</sup>, C. Sanz<sup>1,2</sup>, P. Barrio<sup>1,2</sup>, V. Hurtado-Carneiro<sup>1,2</sup>, D. Burks<sup>3</sup>;<sup>1</sup>University Complutense of Madrid, <sup>2</sup>Centro de Investigación Biomédica en Red de Diabetes y Enfermedades Metabólicas (CIBERDEM), Madrid,<sup>3</sup>Centro de Investigación Príncipe Felipe, Valencia, Spain.

**Background and aims:** Because IRS-2 plays an important role on hepatic nutrient homeostasis, we investigate the expression of GK and GKR in liver, with the use of two experimental models of insulin receptor substrate-2 deficiency in mice. One of these models correspond to IRS-2(-/-) deficient mice and the second ones IRS-2(-/-) deficient mice with IRS-2 specifically reintroduced into pancreatic β-cells, using rat insulin promoter [RIP-Irs-2/IRS-2(-/-)].

**Materials and methods:** Plasma glucose and insulin concentrations were determined using a glucose oxidase method or by immunoassay, respectively. Detection of GK and GKR were done by Western blotting. mRNA levels were determined by quantitative real-time PCR. Glucose-phosphorylating activities were measured using a spectrophotometric assay with two glucose concentrations: 0.3mM for low-Km hexokinase activities, a concentration at which GK is essentially inactive, and 30 mM a concentration at which all phosphotransferase activities were measured.

**Results:** In female mice of both groups of IRS-2 KO animals, plasma glucose and insulin concentrations increase significantly. Liver GK activities were significantly lower (*p*<0.0001) in IRS-2 (-/-) mice. This finding was not found in RIP-Irs-2/IRS-2(-/-) animal because no differences with wild type mice were found. No changes in hypothalamus GK activities of IRS-2 (-/-) animals were found. In addition, liver GK and GKR mRNA levels of IRS-2 (-/-) were significantly lower, while in RIP-Irs2/IRS-2(-/-) animals both GK and GKR increased up to the levels of wild type animals. Also, liver protein content of GK was lower in IRS-2(-/-) mice than in wild type animals, but GK levels does not recover in RIP-Irs2/IRS-2(-/-).

**Conclusion:** These results suggest that IRS-2 is important to maintain the activity of liver GK and then the metabolic function of this organ. Also, these findings suggest that the differences between liver and brain GKs may be explained because the expression of hepatic but not brain GK is controlled by insulin. Thus, when β-cell recovers the presence of IRS-2 in KO mice the reduction of GK activity and protein content were not observed.

### Bscl2<sup>-/-</sup> mice are lipodystrophic, hypotriglyceridaemic and displayed diabetic cardiomyopathy

X. Prieur<sup>1</sup>, M. Takahashi<sup>2</sup>, M. Nemani<sup>3</sup>, L. Dollet<sup>1</sup>, B. Pillot<sup>1</sup>, C. Mounier<sup>4</sup>, J. Capeau<sup>3</sup>, M. Lathrop<sup>3</sup>, G. Toumaniantz<sup>1</sup>, T. Le Tourneau<sup>1</sup>, B. Cariou<sup>1</sup>, P. Costet<sup>1</sup>, J. Magré<sup>1</sup>;<sup>1</sup>UMR 1087, Nantes, France, <sup>2</sup>CEA, Evry, France, <sup>3</sup>UMR 938, Paris, France,<sup>4</sup>UQAM, Montreal, Canada.

**Aim:** Berardinelli-Seip congenital lipodystrophy (BSCL) is a rare recessive disorder characterized by a near total absence of adipose tissue and severe insulin resistance. Patients with mutations in *BSCL2*, the gene encoding seipin, used to display also cardiomyopathy. We aimed to understand the physiopathological mechanism of BSCL linked to seipin deficiency.

**Method:** *Bscl2*-deficient mice (*Bscl2*<sup>-/-</sup>) were generated and phenotyped. An adipocyte differentiation model has been developed using mouse embryonic fibroblast.

**Results:** *Bscl2*<sup>-/-</sup> mice showed a massive and early loss of adipose tissue, with plasma leptin and adiponectin levels decreased by ≈ 80%. Using embryonic fibroblasts from these mice, we found that lipotrophy is due to a combination of both impaired adipocyte differentiation and increased lipolysis. The adipogenesis impairment was partially rescued with PPARγ agonist rosiglitazone. In addition, the adipocyte differentiation rate improved when phosphatidic acid (PA) production was inhibited with lisofylline P, which suggests that abnormal PA accumulation might partially explain the adipogenesis default caused by seipin-deficiency. *Bscl2*<sup>-/-</sup> mice displayed glucose intolerance, insulin resistance and hepatic steatosis. Surprisingly, *Bscl2*<sup>-/-</sup> mice exhibited hypotriglyceridemia in the fed state (0.74 mg/ml vs 0.99 mg/ml in wild-type mice, *p*< 0.05) that became much more severe after 12 hours of fasting (0.14 mg/ml vs 0.43mg/ml in

wild-type mice,  $p < 0.001$ ). Using kinetic experiments with radiolabelled VLDL, we showed that hypotriglyceridemia is likely due to an acceleration of hepatic VLDL clearance and fatty acid uptake in *Bscl2*<sup>-/-</sup> mice. Finally, using echocardiography, we have shown that *Bscl2*<sup>-/-</sup> mice exhibited impaired left ventricular diastolic function classic of diabetic cardiomyopathy from the age of 2 months that got worse with age. At 10 months old, *Bscl2*<sup>-/-</sup> mice display an increase of heart weight ( $230 \pm 38$  mg vs  $178 \pm 19$  mg in wild-type mice,  $p < 0.05$ ) associated with a tendency in ventricular cavity dilatation.

**Conclusion:** Collectively our data suggest that seipin plays a key role in adipose tissue function and in adipocyte storage capacity and *Bscl2*<sup>-/-</sup> mice constitute a new monogenic model of diabetic cardiomyopathy.

### Effect of chronic caffeine administration on Glut-4, AMPK expression and plasma catecholamines in age-induced insulin resistance

J.F. Sacramento<sup>1</sup>, M.J. Ribeiro<sup>1</sup>, C. Gonzalez<sup>2</sup>, D.D. Antunes<sup>1</sup>, M.P. Guarino<sup>1</sup>, S.V. Conde<sup>1</sup>;

<sup>1</sup>Farmacologia, CEDOC, Faculdade Ciências Médicas, Universidade Nova de Lisboa, Lisboa, Portugal, <sup>2</sup>Bioquímica y Biología Molecular y Fisiología, Facultad Medicina, Universidad Valladolid, IBGM, CSIC, Spain.

**Background and aims:** Our group has recently shown that chronic caffeine intake prevents the development of insulin resistance in high fat and high sucrose rats through a mechanism related with a decrease in sympathetic nervous system activity. We have also showed that chronic caffeine administration reverses IR in aged rats. Herein we investigated if the mechanism behind caffeine reversion of age-induced insulin resistance involves effects on sympathetic nervous system activity, measured as plasma catecholamines, and/or altered expression of GLUT-4, AMPK expression and AMPK activity in insulin-sensitive tissues.

**Materials and methods:** Six groups of rats were used: 3 months old (3M), 3 months caffeine-treated (3MCaf), 12 months old (12M), 12 months caffeine-treated (12MCaf), 24 months old (24M) and 24 months caffeine-treated (24MCaf). Caffeine was administered in drinking water (1g/l) during 15 days. The insulin tolerance test (ITT) was used to measure insulin sensitivity. Catecholamines were measured in serum by HPLC with electrochemical detection. GLUT-4, AMPK $\alpha$ 1 and AMPK $\alpha$ 1 Thr172 expression was determined by Western Blot in skeletal muscle and adipose tissue and normalized to loading protein.

**Results:** The decrease in insulin sensitivity induced by aging was reversed by chronic caffeine intake. Circulating catecholamines were diminished at 12M and 24M rats by 27.2 and 63.8%, respectively and caffeine intake did not alter those values. Glut4 expression decreased by 60.5% in skeletal muscle in 24M rats and chronic caffeine intake restored Glut4 to control levels. AMPK  $\alpha$ 1 expression in skeletal muscle significantly decreased in both 12M and 24M rats by 59.8% and 58.6% respectively, and chronic caffeine intake did not modify those values. Furthermore, caffeine intake did not change AMPK activity in skeletal muscle measured as AMPK $\alpha$ 1 Thr172 expression.

**Conclusion:** Chronic caffeine intake reverses age-induced insulin resistance in rats, an effect that was independent of sympathetic nervous system activity and AMPK expression and activity in skeletal muscle. Our results suggest that the effect of caffeine on insulin sensitivity in aged rats involves an increase in skeletal muscle glucose uptake.

### Effect of reducing PP2A expression in central and peripheral insulin signalling

P.K. Picardi, J. Caldeira, R. Bortolatti, A. Caricilli, M. Saad; Morphology and Pathology, Faculty Medicine of Jundiaí, Brazil.

**Background and aims:** Protein phosphatase 2A (PP2A) is a multimeric serine/threonine phosphatase which has multiple functions. However, the potential involvement of PP2A in insulin's metabolic signaling pathway is presently unknown. Brain insulin resistant state is characterized by disturbances in transducing the signal from IR/IRS/AKT, changing feeding behaviour and body weight. We showed that diet induced obese rats (DIO) have a marked increase in PP2A protein expression in the hypothalamus.

**Materials and methods:** Thus, we generated a selective, transient reduction in PP2A by infusion of an antisense oligonucleotide designed to blunt the

expression of PP2A in rat hypothalamic areas surrounding the third ventricle in control and obese rats. Insulin signaling was evaluated by western blot.

**Results:** The selective decrease in hypothalamic PP2A resulted in decreased food intake, reduced body weight, reduced adiposity after high-fat feeding, improved insulin action and signaling in hypothalamus and muscle. Central and peripheral insulin signaling was increased by phosphorylation of AKT in PP2A ASO treated rats. No significant changes in the activation of the IR and IRS-1. To assess the impact of hypothalamic PP2A down-regulation on the peripheral action of insulin, we performed hyperinsulinemic-euglycemic clamp studies. The insulin action on peripheral glucose uptake was increased.

**Conclusion:** We have demonstrated an important role of hypothalamic PP2A in the modulation of energy balance, insulin action, and glucose metabolism. Thus, the reduction in hypothalamic PP2A should be sufficient to promote an appreciable weight reduction and access to the brain may also be necessary to optimally improve insulin sensitivity and glucose homeostasis.

### Inhibition of 72k-5ptase improves insulin signal transduction and corrects defective glucose homeostasis in diet-induced obesity

L.A. Velloso, D. Bertelli, E.R. Roman, E.P. De Arujo; University of Campinas, Brazil.

**Background and aims:** The 72 kDa inositol polyphosphate 5-phosphatase E (72k 5ptase) controls signal transduction through the catalytic dephosphorylation of the 5-position of membrane-bound phosphoinositides. The reduction of 72k 5ptase expression in the hypothalamus, results in improved hypothalamic insulin signal transduction and reduction of food intake and body mass.

**Materials and methods:** Here, we evaluated the tissue distribution and the impact of obesity on the expression of 72k 5ptase in peripheral tissues of experimental animals. In addition, insulin signal transduction and action were determined in an animal model of obesity and insulin resistance treated with an antisense oligonucleotide that reduce 72k 5ptase expression.

**Results:** In lean Wistar rats, 72k 5ptase mRNA and protein are found in highest levels in heart, skeletal muscle and white adipose tissue. In three distinct models of obesity, Wistar rats and Swiss mice fed on high fat diet and leptin deficient ob/ob mice, the expression of 72k 5ptase is increased in skeletal muscle and adipose tissue. The treatment of obese Swiss mice with an anti-72k 5ptase antisense oligonucleotide results in significant reduction of 72k 5ptase catalytic activity, which is accompanied by reduced food intake and body mass and improved insulin signal transduction and action as determined by immunoblotting and clamp studies, respectively.

**Conclusion:** The 72k 5ptase is expressed in several tissues of rodents; obesity is accompanied by an increase on its expression in insulin sensitive tissues while the inhibition of 72k 5ptase reduces body mass and improves whole body insulin action.

### Cyclosporine A and sirolimus treatments impair glucose and lipid metabolism in vivo

P.C.M. Lopes<sup>1</sup>, J. Sereno<sup>2</sup>, A. Furhmann<sup>1</sup>, J.R. Pedro<sup>1</sup>, F. Reis<sup>2</sup>, E. Carvalho<sup>1,3</sup>; <sup>1</sup>Zoology, Center for Neuroscience and Cell Biology, Coimbra, <sup>2</sup>Medicine Faculty, Institute of Pharmacology & Experimental Therapy, Coimbra, <sup>3</sup>The Portuguese Diabetes Association (APDP), Lisbon, Portugal.

**Background and aims:** Immunosuppressive agents (IA) are important in preventing allograft rejection after organ transplantation. Cyclosporine A (CsA), a calcineurin inhibitor, is one of the most effective and used drugs in this field but promotes serious undesirable side effects, including post-transplant diabetes (PTD). Discovering new and more effective drugs has been a challenge. Sirolimus (SRL) is a new option presenting an identical efficacy with apparent less side effects. Nonetheless, their cellular and molecular mechanisms remain to be fully elucidated. The aim of this study was to assess, in Wistar rats, the effects of CsA and SRL treatments for 3 and 9 weeks, as well as, the putative benefits of replacement of CsA with SRL.

**Material and methods:** Rats were treated with CsA (5 mg/kg/day) or SRL (1 mg/kg/day) alone for either 3 or 9 weeks, in combination (CsA for 3 weeks followed by SRL for 6 weeks) or vehicle alone. At the end of treatments, glucose tolerance tests (GTT) were performed. After sacrifice, insulin-stimulated

glucose uptake was measured in isolated epididymal adipocytes, tissues were harvested for PCR and WB analysis and blood was collected to evaluate biochemical parameters.

**Results:** During a GTT, CsA 5 mg/kg/day caused a significant increase ( $287,8 \pm 31,9$  mg/dl vs. vehicle -  $183 \pm 33,9$  at 15 min;  $p < 0,01$ ) in blood glucose at 3 weeks, worsening the effect for the 9 weeks treatments ( $462,2 \pm 51,2$  mg/dl) compared to vehicle ( $375,8 \pm 22,4$  mg/dl,  $p < 0,01$ ) at 15 min, and at 30 min ( $484,2 \pm 50,9$  vs.  $313,4 \pm 15,3$ ,  $p < 0,001$ ). This effect was not significantly different with either SRL or for the combined treatments compared to control. In addition, insulin-stimulated glucose uptake is significantly impaired at both 3 and 9 weeks exposure to either drug compared to vehicle treated animals (presenting a decrease of 20% for the insulin response). In addition, while there is no difference in IRS1 gene expression in fat at 3 weeks, GLUT4 gene expression was decreased for the SRL treatment ( $25,91 \pm 3,3$  vs. vehicle  $52,24 \pm 4,2$ ;  $p < 0,001$ ). At 9 weeks serum triglycerides are increased with CsA treatment ( $196,04 \pm 18,03$  mg/dl) compared to either SRL ( $130,6 \pm 13,6$  mg/dl) or vehicle ( $107,4 \pm 5,7$ ;  $p < 0,05$ ). However, in liver, we observed an increase in lipids for SRL treated animals ( $5,5 \pm 0,6$  mg/dl) compared to vehicle ( $3,7 \pm 0,7$  mg/dl).

**Conclusion:** These results demonstrate that *in vivo* treatment of rats with either CsA or SRL impairs lipid metabolism, insulin-stimulated glucose uptake in isolated adipocytes and CsA causes glucose intolerance. These effects may be responsible for the development of post-transplant diabetes.

**The triglyceride content in skeletal muscle is associated with hepatic but not peripheral insulin resistance in elderly twins**

L.G. Grunnet<sup>1</sup>, E. Laurila<sup>2</sup>, O. Hansson<sup>2</sup>, P. Almgren<sup>2</sup>, L. Groop<sup>2</sup>, P. Poulsen<sup>3</sup>, A. Vaag<sup>1</sup>;

<sup>1</sup>Diabetes and Metabolism, Rigshospitalet, Copenhagen N, Denmark,

<sup>2</sup>Department of Clinical Sciences, Diabetes and Endocrinology, Malmö University Hospital, Sweden, <sup>3</sup>Novo Nordisk A/S, Bagsværd, Denmark.

**Background and aims:** Intramyocellular triglycerides (IMTG) have been associated with insulin resistance. We investigated the predictors and impact of IMTG on several metabolic parameters including peripheral and hepatic insulin resistance in elderly twins.

**Materials and methods:** Seventy-four elderly same-sex twins underwent hyperinsulinaemic euglycaemic clamps preceded by an intravenous glucose tolerance test. Aerobic capacity ( $VO_{2max}$ ) and body composition (DEXA scan) was determined in all twins. A biopsy from the vastus lateralis muscle was excised in the fasting state. The muscle triacylglycerol content was analysed by biochemical extraction from these biopsies.

**Results:** The percentage of total body fat was the only independent predictor of IMTG content. After adjustment for trunk fat percentages and sex, IMTG level was significantly associated to fasting plasma levels of glucose and insulin as well as hepatic insulin resistance. However, the association was weakened after adjustment for total fat percentages. A 1 SD (34.5 mmol/kg dry weight) increase in IMTG content was associated with a 24% increase of hepatic insulin resistance. No association between IMTG content and peripheral insulin sensitivity was observed.

**Conclusion:** IMTG content is associated with hepatic but not peripheral insulin resistance in elderly twins. We speculate that IMTG content may reflect the general ectopic accumulation of triglycerides including fat in the liver.

**Diacylglycerol activation of PKC $\theta$  mediates insulin resistance in hyperlipidaemic, obese and type 2 diabetic states**

J. Szendroedi<sup>1</sup>, T. Yoshimura<sup>2</sup>, E. Phielix<sup>1</sup>, M. Marcucci<sup>2</sup>, D. Zhang<sup>2</sup>,

C. Herder<sup>1</sup>, P. Nowotny<sup>1</sup>, G. Shulman<sup>2</sup>, M. Roden<sup>1</sup>;

<sup>1</sup>German Diabetes Center, Duesseldorf, Germany, <sup>2</sup>Yale School of Medicine, New Haven, USA.

**Background and aims:** Lipotoxicity may lead to systemic subclinical inflammation and/or raise myocellular lipid metabolites [ceramides, diacylglycerols (DAGs)] both of which may also explain insulin resistance associated with obesity and type 2 diabetes (T2D). Here we examine the mechanisms underlying (i) lipid-induced muscle insulin resistance in healthy humans (CON,  $n=12$ ,  $30 \pm 5$  years, BMI:  $24 \pm 2$  kg/m<sup>2</sup>) and (ii) insulin resistance in obese, glucose tolerant humans (OB,  $n=5$ ,  $26 \pm 2$  years,  $45 \pm 3$  kg/m<sup>2</sup>) and patients with T2D (T2D,  $n=4$ ,  $61 \pm 1$  years,  $35 \pm 3$  kg/m<sup>2</sup>).

**Materials and methods:** We measured circulating cytokines (TNF $\alpha$ , IL-6, sICAM, adiponectin, RBP-4), intramuscular DAG and ceramide contents, activities of protein kinase C isoforms (PKC  $\beta$ ,  $\delta$ ,  $\theta$ ) before, at 2.5 h and 4 h lipid or glycerol infusion in CON and at baseline in OB and T2D. We measured insulin sensitivity employing hyperinsulinemic-euglycemic clamps combined with [6,6-<sup>2</sup>H<sub>2</sub>]glucose.

**Results:** Whole-body insulin-stimulated glucose disposal was 57% lower during lipid infusion ( $P < 10^{-6}$ ) than during glycerol infusion. Myocellular total DAG content increased ~2 fold ( $P < 0.005$ ) at 2.5 h and remained ~1.4 fold higher ( $P < 0.05$ ) at 4 h of the lipid infusion. Muscle PKC $\theta$  activity increased by 64% ( $P < 0.005$ ) at 4 h of the lipid infusion. Muscle ceramides and circulating cytokines content did not change. Insulin-stimulated glucose disposal was 78% and 88% lower in OB and T2D (both  $P < 0.005$  vs. CON). Cytosolic DAGs were 180% and 220% greater in OB and T2D than in CON (both  $P < 0.0001$  vs. CON), while muscle ceramide content was not increased compared to CON. Muscle PKC $\theta$  activity was 39% higher in OB and 125% higher in T2D compared to CON ( $P < 0.05$ ).

**Conclusion:** In conclusion, these data support the hypothesis that DAG-induced activation of PKC $\theta$  is responsible for muscle insulin resistance during lipid infusion as well as for the insulin resistance observed in human obesity and type 2 diabetes.

### One week of treatment with the IL-1 receptor antagonist anakinra improves insulin sensitivity in patients with type 1 diabetes mellitus: results from a clinical trial

E.J.P. van Asseldonk, P.C. van Poppel, D.B. Ballak, R. Stienstra, M.G. Netea, C.J. Tack;

General Internal Medicine, Radboud University Nijmegen Medical Centre, Netherlands.

**Background and aims:** Although typically associated with type 2 diabetes, insulin resistance may also play an important role in the pathophysiology of type 1 diabetes mellitus. Once diabetes has emerged chronically elevated glucose levels further induce insulin resistance (glucose toxicity). We and others have found strong evidence that obesity induces inflammatory changes involving release of the potent pro-inflammatory cytokine Interleukin-1 $\beta$  (IL-1 $\beta$ ) at the level of the fat tissue, which is partly triggered by elevated glucose levels. We hypothesized that treatment with an IL-1 $\beta$  receptor antagonist should improve obesity- and hyperglycemia-associated insulin resistance. Glucose toxicity affects both beta cell function as well as insulin sensitivity. As patients with longstanding type 1 diabetes have no residual beta cell function, any improvement in insulin sensitivity must be a direct effect and cannot be secondary to reduced glucose toxicity leading to improved beta cell function. In the present study we investigated whether the IL-1 receptor antagonist anakinra was able to improve insulin sensitivity in insulin resistant patients with longstanding, type 1 diabetes.

**Materials and methods:** Subjects with type 1 diabetes were treated with anakinra 100 mg s.c. once daily for 1 week. Before, at the end of the treatment week and four weeks later a set of measurements were performed. Inclusion criteria: age  $\geq 18$ ,  $\leq 65$  yrs, type 1 diabetes  $> 5$  years, BMI  $\geq 25$  kg/m<sup>2</sup> insulin requirement  $> 0.5$  IE/kg bodyweight and HbA1c  $> 7.5\%$  with stable glycemic control. A total of 14 patients were included in the study. Insulin sensitivity (primary endpoint) was evaluated using a euglycemic hyperinsulinemic clamp. Patients recorded at least four times daily glucose levels and insulin usage before, at the end of the treatment period and four weeks later.

**Results:** All subjects (F:M = 4:10) completed the study. The subjects did not experience any side effect. Average BMI at baseline was  $31 \pm 1$  kg/m<sup>2</sup> and this did not change during the study. Insulin sensitivity numerically improved after 1 week of anakinra, which effect was sustained over the 4 weeks after the intervention (glucose disposal rate before anakinra treatment  $34.4 \pm 3.7$ , directly after anakinra  $39.0 \pm 4.0$  (P vs baseline 0.22), four weeks after anakinra  $39.3 \pm 3.2$   $\mu$ mol/kg/min (P vs baseline  $< 0.05$ )). Patients reported significantly lower glucose levels at the end and four weeks after anakinra treatment, while using significantly less insulin (mean glucose level at baseline  $9.73 \pm 0.49$ , directly after anakinra  $8.50 \pm 0.43$  (P vs baseline  $< 0.01$ ), four weeks after anakinra  $8.29 \pm 0.59$  mmol/l (P vs baseline  $< 0.05$ ), insulin usage at baseline  $80 \pm 9$ , at the end of anakinra treatment  $68 \pm 7$  (P vs baseline  $< 0.05$ ), four weeks after anakinra  $68 \pm 8$  IE/day (P vs baseline  $< 0.05$ ). HbA1c was  $8.57\%$  at baseline and did not change during the study. Leukocyte and neutrophil counts significantly decreased at the end and four weeks after anakinra treatment.

**Conclusion:** One week of treatment with the IL-receptor antagonist anakinra improves insulin sensitivity and glycemic control in subjects with type 1 diabetes mellitus, which effect is sustained for at least four weeks. These results support an important role for IL-1 in insulin resistant type 1 diabetes and suggest that interventions aimed at blocking its effects may be beneficial.

### Impact of low birth weight on insulin signalling in muscle precursor cells

N. Schultz<sup>1</sup>, M. Friedrichsen<sup>1</sup>, C. Broholm<sup>1</sup>, B. Mortensen<sup>2</sup>, B. Pedersen<sup>3</sup>, A. Vaag<sup>1</sup>;

<sup>1</sup>Department of Endocrinology, Rigshospitalet, Copenhagen, <sup>2</sup>Steno Diabetes Center, Gentofte, <sup>3</sup>Centre of Inflammation and Metabolism, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** Low birth weight (LBW) is a marker of an adverse intrauterine environment and is associated with an increased prevalence of Type 2 Diabetes (T2D). Insulin resistance in skeletal muscle represents a key player in T2D development and has previously been associated with birth weight. Studies of muscle biopsies obtained from young men with LBW documented a range of molecular changes relevant to risk of T2D including reduced expression of genes and proteins involved in insulin signaling, altered fiber type composition and more recently differential epigenetic changes, indicating more profound and fundamental changes of their muscle cell functions. We hypothesize that the metabolic and structural changes observed in skeletal muscle of individuals with LBW is associated with an altered function of muscle precursor cells.

**Materials and methods:** Young males with either LBW ( $\leq 10^{\text{th}}$  percentile, n=10) or normal birth weight (NBW) ( $50^{\text{th}} \leq \text{birth weight} \leq 90^{\text{th}}$  percentile, n=9) were studied. Clinical and metabolic characteristic were obtained, and skeletal muscle biopsies were taken. Primary human differentiated myotubes were established from isolated muscle precursors cells, and their differentiation potential and insulin-signaling were investigated. Gene expression of several molecular markers of muscle precursor cell differentiation, including MyoD, Myogenin and Myosin Heavy Chain, were analyzed by rtPCR. Insulin signaling was evaluated by western blotting of p85 and Akt (total Akt and pAkt<sup>Thr308</sup>).

**Results:** LBW subjects displayed a lower weight, height and lean body mass, compared to NBW subjects. The insulin response in the cultured human myotubes, calculated as the fold change of Akt-Thr308 phosphorylation (pAkt<sup>Thr308</sup>) from basal levels, was reduced in LBW individuals (p=0.01). No significant difference in basal and insulin stimulated p85 and Akt protein levels were seen between the two groups. No difference in the differentiation potential between the LBW and NBW group was seen.

**Conclusion:** The findings support the view of fundamental molecular changes of cell functions including defective insulin signaling at the level of pAkt<sup>Thr308</sup> in LBW subjects, contributing to the decreased insulin sensitivity and increased risk of T2D in LBW individuals.

### Iron metabolism-related gene expressions in human adipose tissue in association with obesity and insulin sensitivity

J.M. Fernández-Real<sup>1</sup>, J. Moreno-Navarrete<sup>1</sup>, V. Catalan<sup>2</sup>, F. Ortega<sup>1</sup>, J. Gomez-Ambrosi<sup>2</sup>, M. Moreno<sup>3</sup>, M. Serrano<sup>1</sup>, W. Ricart<sup>1</sup>, C. Diéguez<sup>3</sup>, G. Frühbeck<sup>2</sup>;

<sup>1</sup>Hospital of Girona, <sup>2</sup>Clínica Universitaria de Navarra, Pamplona,

<sup>3</sup>University of Santiago de Compostela, Spain.

**Background and aims:** Recent studies have shown a strong link among iron, obesity-related metabolic disturbances and insulin resistance. To the best of our knowledge, no studies have explored the gene expression of iron related genes in human adipose tissue in association with insulin resistance. To gain insight in the possible effects of iron in adipose tissue physiology, we aimed to investigate iron related genes in human adipose tissue according to obesity, insulin resistance and type 2 diabetes.

**Materials and methods:** Ferroportin 1 (FPN1), transferrin (TF), L-ferritin (FTL) and iron regulatory protein 1 (IRP1) expression (Real Time PCR) were analyzed in three independent cohorts of subjects with different degrees of obesity: cohort 1 [91 visceral (VAT) and 89 subcutaneous (SAT) adipose tissue samples]; cohort 2 [69 VAT samples]; and in a third cohort of morbidly obese subjects with different degrees of insulin action (measured using euglycemic clamp) [32 paired SAT and VAT samples]. Circulating levels of total and unsaturated transferrin were also measured.

**Results:** TF, IRP1, FTL and FPN1 gene expression were detected at high levels in both SAT and VAT. In the first and second cohort, in both VAT and SAT, TF and IRP1 gene expression were significantly and negatively associated with BMI, HOMA<sub>IR</sub> and fasting triglycerides and positively associated with adipogenic genes [PPAR $\gamma$ , GLUT4, IRS1, FASN and ACC1 (r coefficients

between 0.35 and 0.66, *p* values between 0.005 and 0.0001). FTL and FPN1 gene expression were significantly and positively associated with BMI, HO-MA<sub>IR</sub> and negatively associated with adipogenic genes [GLUT4, IRS1, FASN and ACC1 (*r* coefficients between -0.31 and -0.57, *p* values between 0.007 and 0.0001)]. Finally, in the third cohort, TF and FTL1 gene expression in VAT were oppositely linked to insulin action (*r*= 0.45, *p*=0.02 and *r*= -0.53, *p*= 0.002, respectively). Interestingly, circulating unsaturated transferrin (iron free) concentration was negatively associated with fasting triglycerides (*r*= -0.30, *p*= 0.006) and glucose (*r*= -0.29, *p*= 0.007), and positively associated with insulin sensitivity (*r*= 0.46, *p*<0.0001).

**Conclusion:** In summary, adipogenic gene expression was positively linked to TF and IRP1 (directly or indirectly associated with iron uptake) while expression levels of FPN1 (an iron export mediator) and FTL (a marker of intracellular iron accumulation) were negatively associated. These data confirms iron as necessary in adipose tissue physiology, while iron in excess could contribute to obesity-associated adipose tissue dysfunction. The strong association of adipose tissue TF gene expression with insulin sensitivity hints at a potential role in the relationship between iron homeostasis and insulin resistance.

### Novel index of insulin sensitivity from fasting biomarkers: validation in the ACT NOW study

W. Gall<sup>1</sup>, N. Musi<sup>2</sup>, R. DeFronzo<sup>2</sup>, D. Tripathy<sup>2</sup>;

<sup>1</sup>Metabolon Inc, Durham, <sup>2</sup>University of Texas Health Science Center, San Antonio, USA.

**Background and aims:** Although insulin sensitivity measured with the euglycemic hyperinsulinemic clamp remains the gold standard, several simple indices from plasma glucose and insulin concentrations have been proposed as surrogate measures. Of the known indices, the Matsuda insulin sensitivity index correlates well with insulin sensitivity measured with the insulin clamp and has been widely used. We describe a new index of insulin sensitivity derived from fasting insulin and novel insulin sensitivity metabolites (alpha-hydroxybutyrate (α-HB), linoleoyl-GPC (L-GPC), oleate), developed from the RISC clamp study, and validate the results in the ACT NOW study. **Materials and methods:** 602 IGT subjects (FPG=105, 2-h PG [OGTT]=168 mg%) were randomized to PIO (45 mg/day) or placebo (PLAC) and followed for 2.4 years. The Matsuda index of insulin sensitivity was derived from the plasma glucose and insulin concentrations during the OGTT at baseline and at study end. Using mass spectrometry, we measured top-ranking insulin sensitivity metabolites (plasma α-HB, L-GPC, oleic acid), before and after treatment with pioglitazone or placebo. The new index of insulin sensitivity was calculated from an algorithm as part of a novel diagnostic test for insulin resistance, Quantose™-IR, and was validated against the Matsuda insulin sensitivity index.

**Results:** 50 PLAC-treated subjects developed diabetes versus 15 PIO-treated subjects (hazard ratio=0.28; 95% CI= 0.16–0.49; *p*<0.0001). The improvement in Matsuda insulin sensitivity index in PIO-treated subjects ( $3.9 \pm 0.2$  to  $7.6 \pm 0.3$ , *p*<0.0001) was significantly greater than in PLAC-treated subjects ( $3.9 \pm 0.2$  to  $5.2 \pm 0.3$ ) (*p* <0.0001 PIO vs PLAC). At baseline there was no difference in the estimated glucose disposal rate, termed Quantose-M, between the PLAC and PIO groups. PIO treatment led to improvement in Quantose-M ( $5.58 \pm 0.1$  to  $7.31 \pm 0.2$ , *p*<0.001), while no change was observed in the PLAC-treated group ( $5.69 \pm 0.1$  to  $5.69 \pm 0.2$ , *p*=ns). The Quantose-M correlated strongly with the Matsuda insulin sensitivity index both at baseline (*r*=0.791, *p*<0.005) and at study end (*r*=0.829, *p*<0.005). The improvement in Quantose-M also correlated well with the improvement in Matsuda index (*r*=0.783, *p*<0.005) and the decrease in α-HB (*r*=0.464, *p*<0.005), a top biomarker of insulin resistance and glucose intolerance.

**Conclusion:** The Quantose-M insulin sensitivity index, derived from a single fasting plasma sample, correlates strongly with the Matsuda index of insulin sensitivity and parallels the change in insulin sensitivity with a therapeutic intervention, pioglitazone, in IGT subjects. This index provides an excellent measure of insulin sensitivity and may have utility in clinical practice, as well as for large scale research studies.

### Pioglitazone decreases hepatic insulin resistance index and improves hepatic metabolic biomarkers in IGT subjects: the ACTNOW study

A. Gastaldelli<sup>1,2</sup>, D. Tripathy<sup>2</sup>, W. Gall<sup>3</sup>, R.A. deFronzo<sup>2</sup>, ACT NOW Investigators<sup>2</sup>;

<sup>1</sup>Metabolism Unit, CNR Institute of Clinical Physiology, Pisa, Italy, <sup>2</sup>Division of Diabetes, University of Texas Health Science Center, San Antonio, USA,

<sup>3</sup>Metabolon, Inc. Diagnostic, Durham, USA.

**Background and aims:** The aim of the study was to examine the effect of insulin sensitizer pioglitazone (PIO) on hepatic insulin resistance (Hep\_IR) and a set of novel biomarkers associated with hepatic oxidative pathway.

**Materials and methods:** 602 IGT subjects were randomized to PIO (45 mg/day) or placebo (PLAC) and followed for an average of 2.4 years (ACT NOW Study). OGTT screening was performed at baseline and at the end of study in the 441 subjects that completed the study (213 PIO and 228 PLAC). Indices of insulin resistance, both peripheral (by Matsuda index, MI) and hepatic (Hep\_IR, according to Vangipurapu), were calculated from OGTT data. Top-ranking insulin sensitivity metabolites, including plasma alpha-hydroxybutyrate (α-HB), linoleoyl-GPC (L-GPC), oleoyl-GPC (O-GPC), glycine (GLYC), glutamic acid (GLUT), serine, betaine, decanoylcarnitine, and oleic acid, were measured before and after treatment with PIO/PLAC.

**Results:** Of the 441 subjects that completed the study 50 (21.9%) PLAC-treated subjects developed type 2 diabetes versus 15 (7.0%) PIO-treated subjects (*p*<0.005). Pioglitazone significantly improved MI (from  $3.9 \pm 0.2$  to  $7.5 \pm 0.3$ , *p*<0.0001), reduced ALT (from  $30 \pm 1$  to  $24 \pm 1$  U/l, *p*<0.0001), AST (from  $26 \pm 1$  to  $22 \pm 1$  U/l, *p*<0.0007) and induced a small but significant improvement in Hep-IR (-4%, *p*<0.0001 vs placebo). There was no significant difference between groups in plasma metabolite concentrations at baseline. At study end PIO-treated individuals had significantly lower α-HB, oleic acid, GLUT, α-HB/GLYC and higher GLYC, serine, O-GPC and L-GPC (all *p*<0.005 vs PLAC). In PIO-treated subjects the improvement in Hep-IR was associated with improvement in FPG (*r*=0.26, *p*<0.0001), 2h-PG (*r*=0.28, *p*<0.0001), MI (*r*=-0.71, *p*<0.0001), and among the metabolites with reduction in GLYC (*r*=-0.19, *p*=0.01). In a multivariate model, in PIO, after accounting for age, gender and center, decrease in Hep-IR (partial *r*=0.20, *p*=0.02), GLUT (partial *r*=0.13, *p*=0.008), α-HB/GLYC (partial *r*=0.31, *p*=0.001) and increase in MI (partial *r*=0.23, *p*<0.001) were significantly associated with protection from development of type 2 diabetes.

**Conclusion:** PIO improves hepatic and peripheral insulin resistance index and modulates novel oxidative stress biomarkers related mainly to hepatic metabolism which may in part explain the beneficial effects of PIO on hepatic insulin sensitivity.

*Clinical Trial Registration Number: NCT00220961*

## 565

### Distinct effects of insulin on bone marrow metabolism in humans

R. Kiviranta<sup>1,2</sup>, T.T. Pham<sup>3</sup>, J.C. Hannukainen<sup>3</sup>, A. Karmi<sup>3</sup>, H. Immonen<sup>3</sup>, M. Soinio<sup>2</sup>, P. Salminen<sup>4</sup>, P. Nuutila<sup>2,3</sup>;

<sup>1</sup>Medical Biochemistry and Genetics, University of Turku, <sup>2</sup>Department of Medicine, Turku University Hospital, <sup>3</sup>Turku PET Centre, <sup>4</sup>Department of Surgery, Turku University Hospital, Finland.

**Background and aims:** In adults, majority of bone marrow space of long bones is filled with fat tissue. Significant amounts of adipocytes are also present among bone and hematopoietic cells within trabecular bone areas such as vertebral bodies. Despite the advances made in understanding the metabolic activity of other fat depots, very little is known about bone marrow fat, its functional role or glucose metabolism. To characterize bone marrow metabolic activity we measured regional glucose uptake in femoral and vertebral bone marrow during fasting and insulin stimulation in normal weight healthy subjects.

**Materials and methods:** Nine healthy adults (Age  $47 \pm 6$  yr, 2 males, 7 females, BMI  $23.7 \pm 1.9$  kg/m<sup>2</sup>) volunteered for the study. The subjects were imaged with positron emission tomography (PET) using <sup>18</sup>F- fluorodeoxyglucose (<sup>18</sup>F-FDG) tracer to measure glucose uptake (GU) in skeletal muscle, abdominal subcutaneous fat, abdominal visceral fat and vertebral and femoral bone marrow. PET imaging was performed at fasting state and during hyperinsulinemic euglycemic clamp to measure basal and insulin-stimulated glucose uptake.

**Results:** Fasting GU in femoral bone marrow that consists mainly of fat tissue was significantly higher than in subcutaneous (sc) fat ( $4.93 \pm 1.58$  μmol/l/

min in femur vs  $2.82 \pm 0.38 \mu\text{mol/l/min}$  in sc fat,  $p < 0.05$ ) but did not significantly differ from visceral fat. Skeletal muscle GU was 56% higher than that of femoral bone marrow ( $p < 0.01$ ). Interestingly, glucose uptake in vertebral bone marrow that contains bone and hematopoietic cells as well as some adipocytes, was five-fold higher than in femur ( $24.78 \pm 4.59$  vs.  $4.93 \pm 1.58 \mu\text{mol/l/min}$ ,  $p < 0.001$ ). Insulin stimulation during clamp induced a four-fold increase in femoral bone marrow GU ( $20.43 \pm 6.00 \mu\text{mol/l/min}$ ,  $p < 0.001$  vs. fasting state), which remained higher than that of subcutaneous and visceral fat. Skeletal muscle showed an expected robust nine-fold increased in GU to  $69.73 \pm 34.42 \mu\text{mol/l/min}$  that was significantly higher than femoral bone marrow. Surprisingly, insulin did not stimulate glucose uptake in vertebral bone marrow ( $25.98 \pm 3.46$  clamp vs  $24.78 \pm 4.59 \mu\text{mol/l/min}$  at fasting) demonstrating that these two bone marrow compartments differ in their metabolic activity.

**Conclusions:** This study shows that glucose metabolism differs significantly between vertebral and femoral bone marrow. Vertebral bone marrow consists of bone and hematopoietic cells and some adipocytes and the glucose uptake of these cells appears to be insulin independent. Conversely, insulin stimulates glucose uptake in the mainly fatty femoral bone marrow to similar extent than it does in brown fat. Moreover, glucose uptake in femoral bone marrow both in fasting state and during hyperinsulinemic euglycemic clamp is higher compared to either subcutaneous or visceral fat underlining the difference between these fat depots. Thus, our data supports the hypothesis of bone marrow fat as functionally distinct “yellow fat”.

### Prevention of obesity and insulin resistance by estrogens: crucial role of ER $\alpha$ activation function 2 (AF-2)

S. Handgraaf<sup>1</sup>, E. Riant<sup>1</sup>, A. Fabre<sup>1</sup>, A. Waget<sup>2</sup>, M.-J. Fouque<sup>1</sup>, A. Krust<sup>3</sup>, P. Chambon<sup>3</sup>, R. Burcelin<sup>2</sup>, J.-F. Arnal<sup>1</sup>, P. Gourdy<sup>1,4</sup>;

<sup>1</sup>Equipe9, Institut of Metabolic and Cardiovascular Diseases, Toulouse,

<sup>2</sup>Equipe2, Institut of Metabolic and Cardiovascular Diseases, Toulouse,

<sup>3</sup>IGBMC, Illkirch, France, <sup>4</sup>Diabetology department, Toulouse, France.

**Background and aims:** Estrogens prevent visceral adiposity, insulin resistance and type 2 diabetes through estrogen receptor alpha (ER $\alpha$ ) activation. This receptor is known to modulate the transcription of many genes through two activation functions (AF-1 and AF-2). We recently demonstrated that, although ER $\alpha$ -AF-1 is absolutely required for the uterine proliferative action of estrogens, it is dispensable for their beneficial effects on atherosclerosis but also on body composition and glucose homeostasis.

**Material and methods:** In order to characterize the involvement of ER $\alpha$ -AF-2 domain in the beneficial effects of estrogens on metabolism, ER $\alpha$ -deficient (ER $\alpha^{-/-}$ ) and AF-2 deficient (AF-2<sup>0</sup>) female mice, have been maintained under high-glucose high-fat-diet until 16 weeks of age, and compared to their respective littermates wild type controls in terms of weight gain, body composition, glucose tolerance and insulin sensitivity ( $n = 8-10$  per genotype). Then, to avoid interference with endogenous steroid levels, female mice were ovariectomized at 4 weeks of age and were implanted with subcutaneous pellets allowing a chronic and stable administration of  $17\beta$ -estradiol (E2,  $80 \mu\text{g/kg/day}$ ) for 12 weeks.

**Results:** As compared to their littermates, ER $\alpha^{-/-}$  and AF-2<sup>0</sup> female mice were both characterized by significantly accelerated weight gain (+111% and +82% in ER $\alpha^{-/-}$  and AF-2<sup>0</sup> mice respectively), massive accumulation of adipose tissue in subcutaneous (+79% and +65% in ER $\alpha^{-/-}$  and AF-2<sup>0</sup> mice) and perigonadic (+104% and +74% in ER $\alpha^{-/-}$  and AF-2<sup>0</sup> mice) sites, glucose intolerance (IPGTT, AUC: +68% and +70% in ER $\alpha^{-/-}$  and AF-2<sup>0</sup> mice) and insulin resistance (ITT, AUC: +40% and +27% for ER $\alpha^{-/-}$  and AF-2<sup>0</sup> mice). Since it was confirmed that ER $\alpha^{-/-}$  mice, and in lesser extent, AF-2<sup>0</sup> mice exhibit a significant increase of endogenous levels of sex steroids, we then studied the effects of chronic E2 administration in ovariectomized female mice under high-fat-diet. As expected, E2 exerted a strong preventive effect against fat mass accumulation in wild-type mice (-77% SC and -81% PG,  $p < 0.001$ ), but also on insulin sensitivity (Hyperinsulinemic clamps, GIR: +50%,  $p < 0.001$ ). This beneficial action on body composition and insulin sensitivity was totally abolished in ER $\alpha^{-/-}$  and AF-2<sup>0</sup> mice.

**Conclusion:** As previously demonstrated for the vasculoprotective action of estrogens, we now provide evidence that ER $\alpha$ -mediated beneficial effects on body composition and glucose tolerance are independent of the AF-1 function, but dependent of the AF-2 function of ER $\alpha$ . These results open the way to a specific modulation of ER $\alpha$  aiming to uncouple the metabolic and vasculoprotective actions from undesired proliferative effects on reproductive tissues.

### Influence of meal timing on glucose metabolism and hyperandrogenism in lean women with polycystic ovary syndrome

J. Wainstein, M. Boaz, Y. Bar-Dayana, D. Jakubowicz;

Diabetes Unit, E. Wolfson Medical Center Tel Aviv University, Holon, Israel.

**Background and aims:** In obese women with polycystic ovary syndrome (PCOS), weight loss improves insulin resistance and hyperandrogenism, resulting in improvement of clinical symptoms. Weight loss is not required in lean PCOS patients; nevertheless, the influence of meal timing and composition on glucose metabolism and hyperandrogenism may have clinical value. In this study we investigate the effects of two isocaloric diets with different meal timing distribution on insulin resistance and hyperandrogenism in lean PCOS patients.

**Methods:** 60 lean PCOS patients (mean age  $29.4 \pm 6.5$  yrs, mean BMI  $22.7 \pm 0.64 \text{ kg/m}^2$ ) were randomized to one of two isocaloric 1500 kcal/day diets

with different meal timing distribution: Subjects in the High Calorie Breakfast Diet (HCB) consumed a 700 kcal breakfast with the macronutrient distribution: carbohydrate:protein:fat: 50:30:20%. Subjects in the High Calorie Dinner diet (HCD) group consumed this identical meal but at dinner. Insulin and glucose response to OGTT and free testosterone were measured at baseline, and after 90 days of dietary intervention.

**Results:** In the HCB group, area under the curve (AUC) glucose decreased from  $708.8 \pm 145.8$  mg/dl/hr at baseline to  $582.6 \pm 134.3$ ,  $p < 0.0001$  at day 90. Similarly, AUC insulin decreased from  $335.3 \pm 161.0$   $\mu$ U/L/hr to  $102.4 \pm 55.2$ ,  $p < 0.0001$ . Additionally, serum testosterone levels decreased from  $3.8 \pm 1.0$  ng/ml vs.  $1.26 \pm 0.68$ ,  $p < 0.0001$ . These values did not change in the HCD group, and change in BMI was not detected in either group.

**Conclusions:** Isocaloric diets with different meal timing distribution influence glucose metabolism and free plasma testosterone levels in lean women with PCOS. High caloric protein and carbohydrate intake at breakfast with reduced intake at dinner results in improved insulin sensitivity and decreased hyperandrogenism. This meal pattern may facilitate the therapeutic management in women with PCOS

### Impaired hepatic lipid homeostasis plays a key role in the development of glucose intolerance induced by testosterone deficiency

T. Senmaru, M. Fukui, H. Okada, Y. Mineoka, M. Asano, M. Yamazaki, G. Hasegawa, N. Nakamura;

Department of Endocrinology and Metabolism, Kyoto Prefectural University of Medicine Graduate School of Medical Science, Japan.

**Background and aims:** Low serum testosterone concentrations are associated with metabolic disorders such as type 2 diabetes and metabolic syndrome, dramatically illustrated by androgen deprivation in men with prostate cancer. However, the precise mechanism is unknown. On the other hand, previous studies suggest that hepatic triglyceride (TG) accumulation is directly responsible for the subsequent development of hepatic insulin resistance and increment of glucose production. In this study, we sought to determine whether the mechanism by which testosterone deficiency causes metabolic disorders is through impaired hepatic lipid homeostasis.

**Materials and methods:** Male C57BL/6J mice aged 7 weeks were either castrated (CX) or sham-operated (SHAM), and then were fed a high-fat diet (HFD: 507.6 kcal/100 g, fat kcal 56.7%) or a normal diet (ND: 346.8 kcal/100 g, fat kcal 10%) for 3 weeks starting at 8 weeks of age. Glucose tolerance was assessed by IPGTT at 11 weeks of age. Serum lipids concentrations and hepatic lipids contents were measured by HPLC and enzyme assay, respectively. Hepatic gene expression involved in glucose and lipid metabolism was analyzed by quantitative RT-PCR.

**Results:** In ND-fed mice, castration did not affect all metabolic parameters. As expected, HFD-feeding increased body weight, fasting blood glucose and serum insulin levels in both SHAM and CX mice. Fasting blood glucose levels were higher in CX mice than SHAM mice ( $189.4 \pm 11.4$  vs  $121.0 \pm 9.3$  mg/dL,  $p < 0.05$ ,  $n = 7$ ). In IPGTT, blood glucose levels at 30, 60 and 120 min after glucose load were also significantly higher in CX mice. It was noteworthy that, under HFD-feeding conditions, serum TG and VLDL levels were markedly lower in CX mice than SHAM mice (TG:  $18.9 \pm 2.2$  vs  $84.1 \pm 3.7$  mg/dL,  $p < 0.01$ ,  $n = 5$ ). Inversely, hepatic TG contents were significantly higher in CX mice than SHAM mice ( $169.3 \pm 10.8$  vs  $100.5 \pm 15.1$  mg/g liver weight,  $p < 0.05$ ,  $n = 5$ ). These findings were consistent with the results of histological analysis showing increased lipid droplets in the liver of HFD-fed CX mice. Furthermore, the expression of lipogenic genes, including sterol regulatory element binding protein-1c, fatty acid synthase and peroxisome proliferator-activated receptor- $\gamma$ , was up-regulated in HFD-fed mice. The upregulation of these genes was enhanced in CX mice. Inversely, the expression of microsomal triglyceride transfer protein, which is closely related to hepatic VLDL-TG secretion, was down-regulated in HFD-fed CX mice. Moreover, the expression of insulin receptor substrate-2 was down-regulated in those mice. These results of gene analysis suggest that the inhibition of hepatic TG release along with the increment of TG production causes the hepatic TG accumulation in HFD-fed CX mice, leading to the development of hepatic insulin resistance. Testosterone supplementation using slow-release pellets ameliorated glucose intolerance and hepatic steatosis in HFD-fed CX mice.

**Conclusion:** Hepatic TG accumulation due to impaired hepatic lipid homeostasis and the subsequent hepatic insulin resistance may play a pivotal role in the development of glucose intolerance induced by testosterone deficiency. A high-fat diet could be an initiating factor for those changes.

## 569

### Gender difference in bone - energy homeostasis: adiponectin versus testosterone mediated osteocalcin action in women versus men?

B. Buday<sup>1</sup>, P.F. Pach<sup>2</sup>, B. Literáti-Nagy<sup>1</sup>, M. Vitai<sup>1</sup>, Z. Vecsei<sup>1</sup>, É. Péterfai<sup>1</sup>, L. Korányi<sup>1</sup>;

<sup>1</sup>Metabolism, DRC, Balatonfüred, <sup>2</sup>Statormine Consulting, Balatonfüzfő, Hungary.

**Background and aims:** The osteoblast-specific protein osteocalcin (OCN) has been found to be involved in glucose metabolism by increasing insulin secretion and improving insulin sensitivity by upregulating the insulin sensitizing adiponectin gene in adipocytes. Recently OCN was also found to enhance testosterone production in the Leydig cells of male mice so OCN might be linked to energy metabolism through testosterone in men. Based on these data it is plausible to suppose that there is a gender difference between the metabolic effect of OCN in humans. Our aim was to compare the metabolic links of OCN between the two genders since there are only few data about the specific gender related aspects of the bone - energy homeostasis.

**Materials and methods:** Our study included 136 women (aged  $49 \pm 9$  years) and 155 men (aged  $42 \pm 13$  years). Glucose tolerance was assessed by OGTT, categorized as normal (NGT), or impaired (IFG, IGT or drug naïve 2DM) glucose tolerance. All subject underwent an IVGTT to assess insulin secretion and a hyperinsulinemic clamp to measure insulin sensitivity (IS). For clamp index whole body ( $M_1$ ) and muscle glucose uptake ( $M_2$ ) values were used. Glucose, insulin values, basic lipid parameters and adipokine levels were measured besides OCN and testosterone values. Body composition was measured by DEXA.

**Results:** For glucose tolerance both female and male populations were heterogeneous. OCN levels did not differ significantly between the NGT and GI groups (IFG, IGT or 2DM subjects). Testosterone levels were significantly lower in GI than NGT men ( $15.51 \pm 5.21$  vs.  $13.44 \pm 6.24$  ng/ml,  $p = 0.03$ ), while no difference was observed in women. OCN showed a strong positive correlation with the adiponectin levels only in females ( $r = 0.254$ ,  $p = 0.0029$ ) independent of age, BMI and body fat percent (BFP), and a positive correlation with clamp measured IS, i.e.  $M_1$  ( $r = 0.22$ ,  $p = 0.009$ ) and  $M_2$  ( $r = 0.21$ ,  $p = 0.015$ ) values, and negative one with HBA1c ( $-0.27$ ,  $p = 0.0015$ ) and the OGTT glucose AUC ( $-0.18$ ,  $p = 0.04$ ), after the adjustment with age. No correlation was found between OCN and adiponectin levels in men. On the other hand, OCN values showed a strong positive correlation with the testosterone levels in males ( $r = 0.243$ ,  $p = 0.0023$ ) which was also independent of age, BMI and BFP. OCN showed positive association with the  $M_1$  ( $r = 0.23$ ,  $p = 0.004$ ) and  $M_2$  ( $r = 0.202$ ,  $p = 0.01$ ) values and negative with BFP ( $r = -0.199$ ,  $p = 0.013$ ), BFP ( $r = -0.23$ ,  $p = 0.004$ ), waist to hip ratio ( $r = -0.41$ ,  $p < 0.0001$ ) and leptin levels ( $r = -0.185$ ,  $p = 0.02$ ) in men. When data were adjusted with testosterone most of these relationships became weaker and disappeared with  $M_2$ , BMI and BFP.

**Conclusion:** The expected, 'classic' adiponectin mediated insulin sensitizing effect of OCN was only supported in females in our study. In men a testosterone mediated metabolic effect of OCN is more probable based on our data. The possible existence of OCN - adiponectin vs. OCN - testosterone axis in females vs. males has to be further investigated in gender specific studies in the future.

### Leptin therapy reverses streptozotocin-induced diabetes by suppressing hepatic glucose production and does not require parasympathetic innervation

H.C. Denroche<sup>1</sup>, E. Tudur<sup>1</sup>, U.H. Neumann<sup>1</sup>, S.D. Covey<sup>2</sup>, T.J. Kieffer<sup>1</sup>;

<sup>1</sup>Cellular and Physiological Sciences, <sup>2</sup>Biochemistry and Molecular Biology, University of British Columbia, Vancouver, Canada.

**Background and aims:** Leptin therapy is capable of normalizing fasting glucose levels in rodent models of insulin-deficient diabetes, independent of increases in circulating insulin levels; yet the mechanisms of this action remain unclear. Hepatic glucose production is a key diabetogenic pathway that contributes to hyperglycemia in insulin-deficient diabetes, and can be down-regulated in part through parasympathetic innervation. We hypothesized that leptin therapy reverses fasting hyperglycemia in insulin-deficient diabetic rodents by suppressing hepatic glucose production, possibly by enhancing parasympathetic tone to the liver.

**Materials and methods:** Blood glucose during a prolonged fast, and liver metabolic parameters were assessed in streptozotocin (STZ)-treated C57BL/6 male mice infused with leptin (STZ-leptin) or vehicle (STZ-vehicle) continu-

ously for 1 week via subcutaneous osmotic pump implants; non-diabetic controls received buffer instead of STZ injection, and sham surgery instead of pump implantation. Secondly, we used this same mode of leptin therapy in STZ-treated C57Bl/6 mice that received either a subdiaphragmatic vagotomy or sham surgery to determine whether leptin therapy could lower blood glucose in STZ-diabetic mice in the absence of hepatic vagal innervation.

**Results:** Ten µg/day leptin administration partially reduced 4 hour fasted blood glucose levels within 5 days of leptin therapy ( $15.3 \pm 0.8$  mmol/l STZ-leptin vs  $24.4 \pm 1.1$  mmol/l STZ-vehicle,  $P < 0.0001$ ) but did not normalize blood glucose concentrations to non-diabetic levels ( $9.0 \pm 0.5$  mmol/l). Interestingly, STZ-diabetic mice treated with leptin showed a robust and progressive fall in blood glucose levels during a prolonged fast from  $16.2 \pm 2.9$  mmol/l at 4 hours, to  $4.6 \pm 0.8$  mmol/l by 15 hours fasting ( $P = 0.004$ ), a total decrease of  $11.6$  mmol/l. In contrast, during this same time frame non-diabetic and STZ-vehicle controls only showed a decrease of  $2.2 \pm 1.0$  and  $3.8 \pm 2.3$  mmol/l respectively, suggesting that leptin therapy dramatically suppresses hepatic glucose production in this model. Moreover, unlike controls, STZ-leptin treated mice were unable to raise plasma ketones during prolonged fasting. Four-hour fasted STZ-leptin treated mice also displayed a ~55% reduction in hepatic *Glut2* expression compared to STZ-vehicle controls, and a severe depletion of hepatic glycogen content ( $0.058 \pm 0.007$  mg/g tissue) compared to STZ-vehicle ( $4.7 \pm 1.2$  mg/g tissue,  $P = 0.003$ ) and non-diabetic controls ( $4.4 \pm 0.9$  mg/g tissue,  $P = 0.0004$ ). We next examined whether the glucose lowering effect of leptin may be mediated by vagal innervation, by determining whether leptin therapy could lower blood glucose in STZ-diabetic mice with a subdiaphragmatic vagotomy. Interestingly, loss of parasympathetic innervation did not block leptin action in this model, as vagotomized mice had a more robust glucose lowering in response to leptin than sham operated controls ( $4.7 \pm 1.6$  mmol/l vs  $18.1 \pm 1.5$  mmol/l on day 3,  $P = 0.0006$ ).

**Conclusion:** Collectively, our data indicate that leptin therapy may lower blood glucose levels in STZ-diabetic mice by suppressing hepatic glucose production, and that the glucose lowering action of leptin in this model of insulin-deficient diabetes is independent of vagal innervation.

*Supported by: Work funded by CIHR. HCD is supported by NSERC. TJK is supported by MSFHR.*

$9.4$  vs  $58.1 \pm 8.3$  years,  $p = 0.001$ ), with earlier diabetes debut ( $40 \pm 10$  vs  $49 \pm 9$  years,  $p = 0.002$ ), higher  $HbA_{1c}$  ( $8.5$  (1.6) vs  $7.3$  (1.6),  $p = 0.014$ ), lower BMI ( $28.7 \pm 4.0$  vs  $33.2 \pm 4.7$ ,  $p = 0.001$ ) and waist circumference ( $100.0$  (10.6) vs  $115.5$  (17.3) cm,  $p < 0.001$ ), and lower 25(OH)D-levels ( $42$  (10) vs  $36$  (14),  $p = 0.015$ ). Ethnicity (beta =  $-6.5$ ,  $p = 0.008$ ) and waist-to-hip ratio (beta =  $-35.5$ ,  $p = 0.012$ ) explained 17% of the variation in 25(OH)D levels.

**Conclusion:** In a bi-ethnic group of patients with type 2 diabetes and hypovitaminosis D we found no correlation of 25(OH)D to insulin resistance or first phase insulin secretion, measured by euglycemic clamp and IVGTT. Despite selecting subjects with 25(OH)D  $< 50$  nmol/l, there were still marked ethnic differences in 25(OH)D levels and anthropometrical measurements, but these differences did not influence insulin sensitivity or insulin secretion. These results do not disprove a relationship between vitamin D and diabetes, but such a relationship, if it exists, is probably more complex than a direct effect on insulin sensitivity or -secretion. It remains to be seen whether a high-dose vitamin D intervention will improve insulin secretion and/or insulin sensitivity in these patients.

*Clinical Trial Registration Number: NCT00992797*

### Effect of 25-hydroxyvitamin D levels on insulin sensitivity and insulin secretion in subjects with type 2 diabetes. Baseline results from a vitamin D intervention trial

C. Wium<sup>1,2</sup>, H.L. Gulseth<sup>3</sup>, E.F. Eriksen<sup>3,2</sup>, K.I. Birkeland<sup>3,2</sup>;

<sup>1</sup>Hormone Laboratory, Oslo University Hospital, <sup>2</sup>University of Oslo,

<sup>3</sup>Department of Endocrinology, Oslo University Hospital, Norway.

**Background and aims:** Emerging evidence suggests a possible link between vitamin D deficiency and type 2 diabetes, although positive results from epidemiological studies and trials with surrogate end points like the HOMA indexes are proving difficult to confirm in RCTs using gold standard methods like the euglycemic clamp. The DIVINE study is an ongoing intervention trial with vitamin D in patients with type 2 diabetes and vitamin D deficiency. We here present baseline data on insulin sensitivity and insulin secretion in relation to 25-hydroxyvitamin D (25(OH)D) levels.

**Materials and methods:** 28 men and 14 women of Nordic ethnicity, and 9 men and 10 women of South Asian ethnicity, with confirmed type 2 diabetes and 25(OH)D levels below 50 nmol/l were included. They underwent an IVGTT with glucose bolus of 0.3 g/kg body weight, followed by a euglycemic, hyperinsulinemic clamp with insulin infusion of 80 mIU/m<sup>2</sup>/min and measurement of endogenous glucose production (EGP) by tracer dilution method, using 6,6-deuterated glucose. The Acute Insulin Response to glucose (AIRg) was calculated as the incremental AUC for insulin from time 0–10 minutes. Insulin sensitivity was expressed as Glucose Infusion Rate (GIR) in µmol/m<sup>2</sup>/min and Insulin Sensitivity Index (ISI =  $100 \times \text{GIR}/\text{s-Insulin}$ ). Anthropometrical measurements and  $HbA_{1c}$  (%) were also taken. Student's *t* test or Mann Whitney U-tests, as appropriate, Spearman's correlations and multiple regression analyses were performed. A *p*-value  $< 0.05$  was regarded as significant.

**Results:** Median (IQR) AIRg was 135 (294), and mean  $\pm$  SD GIR and ISI were  $785 \pm 448$  and  $73.5 \pm 54.3$  respectively, for the whole group. Deuterated glucose measurements were not yet available for all patients, but preliminary calculations from a subgroup indicated similar results when EGP was included. There was no significant correlation of 25(OH)D to AIRg ( $r = -0.06$ ,  $p = 0.66$ ), GIR ( $r = 0.09$ ,  $p = 0.50$ ) or ISI ( $r = 0.03$ ,  $p = 0.82$ ). There were no significant differences in GIR, ISI or AIRg between the sexes, nor between the two ethnicities, despite South Asians being significantly younger ( $49.7 \pm$

### Glucagon, GLP-1 and oxyntomodulin increase resting energy expenditure in man

J.I. Bagger<sup>1,2</sup>, T. Viltsbøll<sup>1</sup>, J.J. Holst<sup>2</sup>, F.K. Knop<sup>1</sup>;

<sup>1</sup>Diabetes Research Division, Gentofte University Hospital, Hellerup,

<sup>2</sup>Biomedical Science, University of Copenhagen, Denmark.

**Background and aims:** The satiety hormone oxyntomodulin (OXM) is a pro-glucagon product with body weight lowering effect. It binds to the glucagon-like peptide-1 (GLP-1) receptor and the glucagon receptor, but the mechanisms behind the body weight reducing effect of OXM remain elusive. We measured the resting energy expenditure (REE) during infusions of saline, GLP-1, glucagon, OXM, and GLP-1+glucagon in healthy subjects.

**Materials and methods:** Indirect calorimetry was used to measure oxygen consumption (VO<sub>2</sub>), carbon dioxide production (VCO<sub>2</sub>), respiratory quotient (RQ) and REE after a 3h-continuous double-blinded infusion of either saline, GLP-1 (1 pmol×kg<sup>-1</sup>×min<sup>-1</sup>), glucagon (0.86pmol×kg<sup>-1</sup>×min<sup>-1</sup>), OXM (3 pmol×kg<sup>-1</sup>×min<sup>-1</sup>) or glucagon+GLP-1 (same doses) in 15 healthy male volunteers (age: 22±2 years (mean±SEM); BMI: 23±0.5 kg/m<sup>2</sup>; HbA<sub>1c</sub>: 5.8±0.1%).

**Results:** Plasma glucose (5.1±0.1 mmol/l) and triglyceride (1.0±0.1 mmol/l) concentrations were similar during the calorimetric measurements. REE was significantly (p<0.05) elevated in response to all peptide infusions compared to saline, with OXM eliciting the most pronounced increase in REE (1,850±124 kcal/day (mean±SD) (saline), 2,004±125 (GLP-1), 1,974±109 (glucagon), 2,057±132 (OXM), 2,014±113 (GLP-1+glucagon)). GLP-1 alone and in combination with glucagon elevated RQ significantly compared to saline whereas OXM tended to decrease RQ (0.85±0.02 (saline), 0.86±0.02, 0.86±0.02 (GLP-1), 0.84±0.02 (OXM), 0.88±0.02 (GLP-1+glucagon)).

**Conclusion:** These data suggest that GLP-1, glucagon and OXM increase REE. Also, our RQ results indicate that OXM increases REE by other mechanisms than GLP-1.

### Preserved postprandial GLP-1 responses in cholecystectomised subjects: no evidence of a physiological role of gallbladder emptying in postprandial GLP-1 release

D.P. Sonne<sup>1</sup>, K.J. Hare<sup>1</sup>, P.C. Martens<sup>2</sup>, J.J. Holst<sup>3</sup>, T. Viltsbøll<sup>1</sup>, F.K. Knop<sup>1</sup>;

<sup>1</sup>Department of Internal Medicine F, Hellerup, <sup>2</sup>Department of Radiology,

Hellerup, <sup>3</sup>Department of Biomedical Sciences, the Panum Institute, Copenhagen, Denmark.

**Background and aims:** Besides their well-established roles in dietary lipid absorption and cholesterol homeostasis, bile acids are increasingly being recognized for their function as metabolic regulators. Preclinical studies suggest that gallbladder emptying - via bile acid-induced activation of the G protein-coupled receptor TGR5 in intestinal L cells - plays a significant role in the secretion of the incretin hormone glucagon-like peptide-1 (GLP-1) and postprandial glucose homeostasis. We hypothesized that human gallbladder emptying potentiates postprandial release of GLP-1 and aimed to evaluate whether cholecystectomized patients exhibit impaired postprandial GLP-1 secretion.

**Materials and methods:** Ten cholecystectomized subjects (age: 49±4 years (mean±SEM); BMI: 25±0.4 kg/m<sup>2</sup>; HbA<sub>1c</sub>: 5.9±0.1%) and 10 healthy age-, gender- and BMI-matched control subjects (age: 48±4 years; BMI: 24±0.5 kg/m<sup>2</sup>; HbA<sub>1c</sub>: 5.7±0.1%) were studied. None had any family history of diabetes and all had normal oral glucose tolerance according to 75 g-oral glucose tolerance test (OGTT). Subjects received a 2,200 kJ-standardized fat-rich liquid meal (with acetaminophen for evaluation of gastric emptying) during which blood samples were drawn and duodenal aspirate (for evaluation of intraduodenal bile acid concentrations) was collected through a duodenal tube placed fluoroscopically.

**Results:** Similar fasting plasma glucose levels were observed in the two groups (5.4±0.1 (mean±SEM) vs. 5.2±0.1 mmol/l, P=0.2) whereas postprandial plasma glucose (PPG) excursions were exaggerated in the cholecystectomized group compared to control subjects (1,431±31 vs. 1,313±36 mmol/l×240 min, P=0.023). Similar fasting plasma GLP-1 concentrations were observed in the two groups, and subjects without a gallbladder exhibited pre-

served postprandial responses of GLP-1 compared to the carefully matched healthy control subjects (3,707±400 vs. 3,165±287 pmol/l×240 min, P=0.29). **Conclusion:** In conclusion, cholecystectomized subjects exhibit preserved postprandial GLP-1 responses suggesting that the physiologically important role of gallbladder emptying for postprandial GLP-1 release indicated by preclinical studies is of less importance in humans. Thus, the physiological relevance of potentiation of GLP-1 release via bile acid-induced activation of TGR5 in small intestinal L cells is still questionable in humans.

### CART is expressed in endocrine cells, including K-cells and L-cells, in the human gastrointestinal tract, and CART is released after a carbohydrate-rich meal in humans

L. Shcherbina<sup>1</sup>, E. Östman<sup>2</sup>, J.F. Rehfeld<sup>3</sup>, N. Wierup<sup>1</sup>;

<sup>1</sup>Lund University Diabetes Centre, Malmö, Sweden, <sup>2</sup>Division of Applied

Nutrition and Food Chemistry, Lund, Sweden, <sup>3</sup>Department of Clinical Biochemistry, Rigshospitalet, Copenhagen, Denmark.

**Background and aims:** Cocaine- and amphetamine-regulated transcript (CART) is a regulatory peptide with insulinotropic, glucagonostatic, and anorexigenic properties. We have found CART expression in a hitherto unidentified cell population in human and rodent gastrointestinal (GI) tract. The function and regulation of CART in gut endocrine cells are unknown. The aim of this study was to establish the presence of CART producing endocrine cells along the human GI-tract, as well as to unravel the cellular identity of the CART-expressing cells. A secondary aim was to study regulation of CART expression *in vitro* and CART secretion *in vivo* in humans.

**Materials and methods:** Human specimens covering all parts of the GI-tract (n=10) were examined for CART expression using immunohistochemistry and *in situ* hybridization. Double-immunohistochemistry for all major gastrointestinal hormones was used to identify the CART expressing cells. CART plasma levels were assessed in 14 healthy subjects after a carbohydrate-rich meal. In addition, GLUTag cells were used as an *in vitro* model to study regulation of CART gene expression by QRT-PCR.

**Results:** CART expressing endocrine cells were most prominent in the duodenum and in the antrum part of the stomach, whereas such cells were rare in other parts of the GI-tract. In human duodenum CART was expressed in all the main enteroendocrine cell types studied. Thus, of all CART-expressing cells 75±8% were GIP-producing K-cells, 47±0.4% were serotonin-producing EC-cells, and 36±19% were CCK-producing I-cells. CART was also expressed in minor proportions of GLP-1-producing L-cells, as well as in somatostatin-producing D-cells, neurotensin-producing NT-cells and motilin-producing Mo-cells. In the antrum, the majority of the CART expressing cells was identical to gastrin-producing G-cells. Human plasma CART levels were increased after a carbohydrate-rich meal, with the peak at 60 min. In addition, CART levels correlated positively with glucose and insulin levels 15-30 min after the meal. CART expression was evident in GLUTag cells; therefore this cell line was used to study CART gene regulation. CART mRNA in GLUTag cells was increased by 1mM palmitate, but was not affected by either glucose or oleate. On the other hand, addition of GIP, forskolin and IBMX provoked increased CART mRNA levels.

**Conclusions:** CART is expressed in G-cells in the antrum, as well as in Mo-, NT-, EC-, D-, I-, L-, and K-cells in the duodenum. CART mRNA is increased by palmitate, GIP, and cAMP-elevating agents in GLUTag cells. In humans, CART plasma levels are elevated after a meal, however its origin needs further investigation.

### Effects of advanced glycation end-products on GLP-1 secreting cells

A. Puddu, R. Sanguineti, G.L. Viviani;

Department of Internal Medicine and Medical Specialties, University of Genova, Italy.

**Background and aims:** Glucagon-like peptide-1 (GLP-1), an intestinal hormone involved in glucose homeostasis, is synthesized by posttranslational processing of proglucagon and is secreted from specialized intestinal neuroendocrine cells, in response to dietary nutrients, and to neural and hormonal

signals, like insulin. Hyperglycemia accelerates formation and accumulation of Advanced Glycation End-Products (AGEs), a heterogeneous group of compounds derived from the non-enzymatic reaction of reducing sugars with proteins, lipids or nucleic acids. AGEs are implicated in diabetic complications, in pancreatic  $\beta$ -cell dysfunction, and in induction of insulin resistance. The aim of this study is to investigate whether AGEs can affect function of GLP-1 secreting cells and their responsiveness to insulin.

**Materials and methods:** Glycated serum (GS), prepared by incubating FBS with 50 mmol/l ribose at 37°C for 7 days, was employed to replace part of FBS in the culture medium. The murine enteroendocrine cell line GLUTag cells (kindly provided by Dr Drucker) were cultured for 5 days in the presence of 2 concentrations of AGEs (GS, and 2GS). At the end of the culture: total RNA was extracted and mRNA expression of proglucagon was evaluated by RT-PCR; GLP-1 release was measured following 2 hours incubation with or without 100 nM insulin; insulin-induced phosphorylation of IRS-1, one of the substrate of insulin receptor, was evaluated by Western blot after stimulation with 10 nM insulin for 5'.

**Results:** Exposure of GLUTag cells to AGEs results in increased mRNA expression of proglucagon (GS:  $104.7 \pm 9.24$  %,  $p > 0.05$  vs CTR; 2GS:  $164.7 \pm 8.74$  %,  $p < 0.05$  vs CTR). This change is accompanied to a significant increment of GLP-1 release by cells cultured in presence of AGEs in comparison to cells cultured in standard medium (CTR:  $835.3 \pm 30.75$  fmol/mg prot; GS:  $1023 \pm 6.25$  fmol/mg prot  $p < 0.05$  vs CTR; 2GS:  $1257 \pm 98.96$  fmol/mg prot,  $p < 0.01$  vs CTR). Insulin-induced GLP-1 secretion results in a 1.4 fold increase of GLP-1 secretion in GLUTag cells cultured in standard condition, whereas insulin was unable to stimulate increment of GLP-1 secretion in cells cultured in presence of AGEs (insulin-induced GLP-1 secretion % vs basal: CTR  $141.3 \pm 4.67$ ; GS  $110.5 \pm 9.89$  %,  $p < 0.05$  vs CTR; 2GS  $105.3 \pm 5.31$  %,  $p < 0.05$  vs CTR). Insulin-stimulated IRS-1 phosphorylation at Tyr895 was abrogated by culture with AGEs (insulin-induced IRS-1 phosphorylation % vs unstimulated: CTR  $249 \pm 39$ ; GS  $107 \pm 13$  %,  $p < 0.05$  vs CTR; 2GS  $130 \pm 2$  %,  $p < 0.05$  vs CTR). These data show that AGEs impair GLUTag cell function by: (1) up-regulating the proglucagon gene expression; (2) affecting secretion of GLP-1; and (3) interfering with insulin signal.

**Conclusion:** These results suggest that exposure of GLUTag cells to AGEs, by increasing GLP-1 secretion, could lead the cells to a condition of exhaustion, contributing to the reduced levels of GLP-1 in subjects with T2DM. Moreover abrogation of insulin-stimulated GLP-1 secretion and IRS-1 phosphorylation suggest that AGEs may induce insulin resistance also in GLP-1 secreting cells. It can be speculated that the altered GLP-1 secretion due to AGEs exposure, coupled to reduced insulin-induced GLP-1 secretion, may contribute to the development and worsening of type 2 diabetes and its complications.

## 576

### Cannabinoid receptor 1 activation inhibits secretion of glucose-dependent insulinotropic polypeptide from intestinal K-cells

C.E. Moss<sup>1</sup>, W.J. Marsh<sup>2</sup>, H.E. Parker<sup>1</sup>, E. Ogunnowo-Bada<sup>2</sup>, C.H. Riches<sup>2</sup>, A.M. Habib<sup>1</sup>, M.L. Evans<sup>1</sup>, F.M. Gribble<sup>1</sup>, F. Reimann<sup>1</sup>

<sup>1</sup>Clinical Biochemistry, <sup>2</sup>Medicine, University of Cambridge, UK.

**Background and aims:** Glucose-dependent insulinotropic polypeptide (GIP) is an enteroendocrine hormone which stimulates insulin secretion, and promotes glucose and triglyceride storage. GIP is secreted from K-cells in the duodenum in response to luminal nutrients in a cyclic AMP-dependent manner. As GIP receptor knock-out or pharmacological inhibition and ablation of K-cells have all been shown to be protective in rodent models of obesity, it has been postulated that GIP may serve to link overnutrition to obesity. The aim of this study was to determine if  $G_{q_i}$ -protein coupled receptors could be recruited to lower cyclic AMP levels in and inhibit GIP secretion from K-cells.

**Materials and methods:** Expression of  $G_{q_i}$ -coupled receptors in K-cells (isolated by fluorescent assisted cell sorting from mice expressing yellow fluorescent protein under the control of the GIP-promoter) was detected by Affymetrix 430 2.0 array hybridisation and confirmed by SYBR green qPCR. Hormone secretion from mixed murine intestinal epithelial cultures and in response to an oral glucose tolerance test in rats was assessed by ELISA or MesoScale.

**Results:** Expression analysis revealed expression of the  $G_{q_i}$ -coupled receptor cannabinoid receptor 1 (CNR1) in duodenal K-cells. Isobutyl methyl xanthine (IBMX, 100  $\mu$ M) stimulated GIP secretion from mixed duodenal cultures  $2.9 \pm 0.3$ -fold ( $n=26$ ;  $p < 0.001$  by one way ANOVA with post hoc Bonferroni test), an effect strongly impaired by addition of the cannabinoid receptor 1 (CNR1) agonist methanandamide (mAEA, 10  $\mu$ M,  $89 \pm 9\%$  inhibition,  $n=27$ ,  $p < 0.001$ ). The reverse agonist AM251 (1  $\mu$ M) had no significant

effect on its own but partially prevented mAEA inhibition ( $48 \pm 10\%$  inhibition,  $n=27$ ,  $p < 0.05$ ). Although CNR1 mRNA expression was also detected in small intestinal L-cells, no effect of either mAEA or AM251 was observed on IBMX-stimulated glucagon-like peptide-1 (GLP-1) secretion assayed in parallel from the same samples. Consistent with the in vitro findings, mAEA (10 mg/kg administered 30 minutes before an oral glucose tolerance test in rats) inhibited GIP (area under curve (AUC)  $2900 \pm 400$  ( $n=8$ ) and  $4300 \pm 200$  ( $n=5$ )  $\text{pmol} \cdot \text{min}^{-1} \cdot \text{l}^{-1}$ ;  $p < 0.05$  by Student's t-test), but not GLP-1 secretion (AUC:  $0.14 \pm 0.02$  ( $n=8$ ) and  $0.13 \pm 0.02$  ( $n=5$ )  $\text{pg} \cdot \text{min}^{-1} \cdot \text{l}^{-1}$ , without significantly delaying gastric emptying, monitored by the plasma appearance of acetaminophen co-applied by gavage.

**Conclusion:** GIP secretion can be inhibited by activation of CNR1, demonstrating a previously unreported cross talk between the intestinal endocannabinoid and enteroendocrine systems. CNR1-dependent inhibition of GIP may act to enhance sensitivity to nutrient stimulation, as endocannabinoid levels fall rapidly after feeding. The observed divergence of mAEA effects on GIP and glucagon-like peptide 1 (GLP-1) secretion might allow selective inhibition of K- over L-cell secretion in the treatment of obesity.

### Lower GIP and glucagon responses in metabolically healthy but obese (MHO) subjects in comparison with at risk obese individuals

S. Calanna, S. Piro, A. Di Pino, R.M. Zagami, F. Urbano, F. Purrello, A.M. Rabuazzo;

Clinical and Molecular Biomedicine, University of Catania, Italy.

**Background and aims:** Obesity is widely acknowledged as a crucial risk factor for metabolic complications. Among obese subjects, there is a phenotype of metabolically healthy but obese (MHO) individuals that shows a favorable cardio- metabolic risk profile. We aimed to evaluate the potential mechanisms underlying the metabolic profile of this subset, including alpha and beta cell function and entero-insular axis.

**Materials and methods:** We studied 129 obese and 24 non-obese subjects. Obese participants were defined as MHO or at risk obese, according to the HOMA-IR index (MHO: lower tertile of HOMA-IR,  $n=43$ ; at risk: upper tertile of HOMA-IR index,  $n=41$ ). We investigated insulin, glucagon and incretin responses after a 120' oral glucose tolerance test (75g- OGTT).

**Results:** During OGTT, MHO individuals showed in comparison with at risk subjects: lower glucose, insulin and C-peptide fasting plasma levels and responses during the OGTT; higher disposition index; lower fasting ( $p=0.004$ ) and at 30' ( $p=0.01$ ) plasma glucose-dependent insulinotropic polypeptide (GIP) levels; lower AUC (0-30) for GIP ( $p=0.008$ ); higher glucagon-like peptide-1 (GLP-1) plasma levels at 90' ( $p=0.02$ ) and 120' ( $p=0.02$ ); lower glucagon plasma levels at baseline ( $p=0.04$ ) and at 30' ( $p=0.03$ ); appropriate glucagon suppression after the oral glucose load.

**Conclusion:** Metabolically healthy but obese subjects show, as well as normal weight individuals, a lower diabetogenic profile by virtue of higher disposition index and unaffected entero-insular axis. At risk obese individuals present increased GIP levels that might play a role in determining increased glucagon secretion and inappropriate glucagon responses after glucose load, thus contributing to impaired glucose homeostasis.

### Bioactive incretins levels in humans using novel bioassays reveal kinetics that better correlate with insulin levels than traditional assays

T. Yanagimachi<sup>1</sup>, Y. Fujita<sup>1</sup>, J. Honjo<sup>1</sup>, H. Sakagami<sup>1</sup>, H. Kitsunai<sup>1</sup>, Y. Takiyama<sup>1</sup>, A. Abiko<sup>1</sup>, Y. Makino<sup>1</sup>, T.J. Kieffer<sup>2</sup>, M. Haneda<sup>1</sup>;

<sup>1</sup>Department of Medicine, Asahikawa Medical University, Japan,

<sup>2</sup>Department of Cellular & Physiological Sciences, University of British Columbia, Vancouver, Canada.

**Background and aims:** Glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1) are incretins secreted from the gastrointestinal tract that promote insulin secretion from pancreatic  $\beta$ -cells in a glucose-dependent manner. Both hormones are rapidly cleaved by dipeptidyl peptidase-4 (DPP-4) after secretion into truncated forms that are no longer insulinotropic. Therefore, it is desirable to specifically assay the full-length insulinotropic forms of incretins. Although active GLP-1 levels have been measured by RIA and ELISA, it is unclear if the assays only detect biologically active forms and the measured values are quite variable by each method.

Moreover, currently there is no reliable method to measure bioactive GIP levels. Therefore, we determined active GIP and GLP-1 levels from human blood samples using novel cell-based, receptor-mediated bioassays.

**Materials and methods:** We used the cell lines stably co-transfected with human forms of GIP or GLP-1 receptors, and a cyclic AMP-inducible luciferase expression construct. We incubated the cells in 96-well plates with samples 5 h and then measured luciferase activity via luminometer. We performed a 75 g OGTT in six healthy volunteers and measured total incretin, insulin, C-peptide and glucagon levels by ELISA and active incretin levels by the bioassays in plasma samples.

**Results:** To assess the specificity of the bioassays, we assessed their responsiveness with several synthetic incretin agonists. In the GIP bioassay, GIP (1–42) and short-form GIP (1–30) increased luciferase activity in a concentration dependent. GIP (1–30) yielded approximately 90% activity of GIP (1–42). In the GLP-1 bioassay, GLP-1 (7–36 amide) and exendin-4 produced almost equivalent luciferase activity. In contrast, the GLP-1 analog liraglutide was not as active in the bioassay, with ~18% of GLP-1 (7–36 amide) activity at 1000 pmol/l. In samples collected from human subjects during an OGTT, insulin levels were greatest at 30 min, and C-peptide levels peaked at 60 min after glucose load. Glucagon levels were suppressed by the oral glucose load. Total GIP levels rapidly increased from 0 min ( $18.4 \pm 8.8$  pmol/l) to 15 min ( $52.4 \pm 9.2$  pmol/l) and gradually increased up to 120 min ( $68.8 \pm 11.4$  pmol/l). In contrast, active GIP levels peaked at 30 min (0 min:  $20.7 \pm 3.6$  pmol/l, 30 min:  $89.4 \pm 11.2$  pmol/l) and dropped at 60 min ( $56.0 \pm 3.8$  pmol/l). Notably, active GIP had a positive correlation with the insulin levels ( $r = 0.31$ ,  $p = 0.03$ ). Total GLP-1 levels increased from 0 min ( $16.5 \pm 1.8$  pmol/l) to 30 min ( $24.2 \pm 1.8$  pmol/l) and remained at similar levels up to 120 min ( $25.4 \pm 2.7$  pmol/l). In contrast, active GLP-1 levels reached a peak at 30 min (0 min:  $8.9 \pm 1.4$  pmol/l, 30 min:  $19.1 \pm 5.8$  pmol/l) and dropped at 60 min ( $8.4 \pm 1.0$  pmol/l).

**Conclusion:** The bioassay measuring method for active forms GIP and GLP-1 reveals that the peaks in circulating hormone levels are reached more rapidly than total GIP and GLP-1 levels, and thereafter active incretin levels decreased promptly. This profile of circulating active GIP and GLP-1 better correlated with insulin levels compared to results obtained with the total assays, and thus we propose that the bioassays more accurately reflect the contribution of the incretins in the entero-insular axis.

### Glucagon-like peptide-1 receptor activation with liraglutide enhances hippocampal long-term potentiation mediated through Mash1 in obese diabetic (*ob/ob*) mice

V.A. Gault, D. Porter, C. Holscher, P.R. Flatt;

School of Biomedical Sciences, University of Ulster, Coleraine, UK.

**Background and aims:** Studies have shown that consumption of a high fat diet has adverse effects on learning and memory formation in rodents which has been linked to impaired hippocampal function. Activation of the glucagon-like peptide-1 (GLP-1) receptor signaling machinery has been shown to ameliorate the negative effects of obesity-diabetes on learning and memory however, the mechanisms underlying these beneficial actions remain unclear. Therefore, this study examined effects of daily subcutaneous administration of Liraglutide on hippocampal synaptic plasticity, gene expression and metabolic control in adult obese diabetic (*ob/ob*) mice.

**Materials and methods:** Male obese diabetic (*ob/ob*) mice (14 to 16-weeks old; received twice-daily injections (10:30 h and 16:00 h; sc) of Liraglutide (50 nmol/kg;  $n=8$ ) or saline vehicle (0.9% (w/v) NaCl;  $n=8$ ) over a 21-day period. Body weight, non-fasting plasma glucose and insulin concentrations were monitored at 2 to 3-day intervals. Glucose tolerance (18 mmol/kg; *ip*) and insulin sensitivity tests (50 U/kg; *ip*) were performed at the end of the 21-day study period together with measurement of indirect calorimetry, energy expenditure, locomotor activity and food intake using automated Oxymax CLAMS apparatus. Following measurement of metabolic parameters hippocampal synaptic plasticity was determined by *in vivo* electrophysiological recording of long-term potentiation in region CA1. Additionally, hippocampus was excised ( $n=6$ ) and snap frozen prior to extraction of RNA for gene expression analysis

**Results:** Long-term potentiation (LTP) induced in area CA1 was completely abolished in *ob/ob* mice compared with lean controls ( $F=16.2$ ;  $P<0.001$ ). Deleterious effects on LTP were rescued in *ob/ob* mice treated with Liraglutide ( $F=19.1$ ;  $P<0.001$ ) compared to *ob/ob* saline controls. Indeed, Liraglutide-treated mice exhibited superior LTP profile compared to lean controls ( $F=9.2$ ;  $P<0.01$ ). Expression of hippocampal BDNF and NTRK-2 were not significant-

ly different ( $P>0.05$ ), but synaptophysin and Mash1 were decreased in *ob/ob* mice compared to lean littermates. Moreover, treatment with Liraglutide over 21 days increased the expression of Mash1 in *ob/ob* mice (2.0-fold;  $P<0.01$ ). These changes were associated with significantly reduced plasma glucose (21% reduction;  $P<0.05$ ) and markedly improved plasma insulin concentrations (2.1 to 3.3-fold;  $P<0.05$  to  $P<0.01$ ). Liraglutide also significantly reduced the glycaemic excursion following an intraperitoneal glucose load (AUC values: 22%;  $P<0.05$ ) and markedly enhanced the insulin response to glucose (AUC values: 1.6-fold;  $P<0.05$ ).  $O_2$  consumption,  $CO_2$  production, respiratory exchange ratio and energy expenditure were not altered by Liraglutide therapy. Changes observed were not due to simple dietary restriction alone.

**Conclusion:** These data demonstrate that Liraglutide elicits beneficial effects on metabolic control and synaptic plasticity in mice with severe obesity and insulin resistance mediated in part through increased expression of Mash1 believed to improve hippocampal neurogenesis and cell survival.

### Liraglutide increases FGF-21 activity and insulin sensitivity after treated with Acrp30 knockdown

J. Yanjun<sup>1,2</sup>, L. Li<sup>1,2</sup>, G. Yang<sup>3</sup>;

<sup>1</sup>College of Laboratory Medicine, Chongqing Medical University, <sup>2</sup>the Key Laboratory of Laboratory Medical Diagnostics in Ministry of Education, Chongqing Medical University, <sup>3</sup>The Second Affiliated Hospital, Chongqing Medical University, Chongqing, China.

**Background and aims:** Glucagon-like peptide (GLP-1) is a gut hormone secreted in response to ingestion of carbohydrates, lipids, and mixed meals from the L-cells located in the distal jejunum, ileum and colon/rectum. Fibroblast growth factor-21 (FGF-21) is a regulator of insulin action on glucose and lipid homeostasis. In previous studies, we have shown that plasma FGF-21 levels were elevated in patients with T2DM and in diabetic patients with ketosis, and were decreased in response to treatment with rosiglitazone. In this study, we hypothesized that 1) the combination of HFD, hyperlipidemia, and hypoadiponectinemia can cause more severe insulin resistance; 2) that the insulin resistance ameliorating effects of liraglutide were, at least in part, due to increased FGF-21 activity.

**Materials and methods:** ApoE KO and adiponectin (Acrp30) knockdown mice fed a high-fat diet (HFD) were treated with liraglutide (10 mg/kg, twice daily) for 16 weeks. Ad-*shGFP* or Ad-*shAcrp30* was injected by tail vein at the end of the 14th and 15th week of HFD feeding. Liraglutide (1mg/kg) or saline was given intraperitoneally twice daily for 8 weeks. Mice were divided into following groups: regular chow (Control group), high-fat diet (HF, group), high-fat diet and Ad-*shGFP* (Ad-*shGFP* group). Hyperinsulinemic-euglycemic clamp studies were performed. Glucose rates of appearance (G<sub>Ra</sub>) were determined with 3-[<sup>3</sup>H] glucose. Whole body G<sub>Ra</sub> and glucose uptake (G<sub>Rd</sub>) were calculated using the non-steady-state equation. Liver tissue was procured for histological examination, real-time RT-PCR and western blot analysis.

**Results:** The combination of HFD, ApoE deficiency, and hypoadiponectinemia resulted in an additive effect on insulin resistance. FGF-21 mRNA expressions in both liver and adipose tissues were significantly increased while FGF-21 receptor 1 (FGFR-1) and  $\beta$ -Klotho mRNA levels in adipose tissue, as well as FGFR-1-3 and  $\beta$ -Klotho mRNA levels in liver were significantly decreased in this model. Liraglutide treatment markedly improved insulin resistance and increased FGF-21 expression in liver and FGFR-3 in adipose tissue, restored  $\beta$ -Klotho and cFos mRNA expression in adipose tissue as well as FGFR-1-3,  $\beta$ -Klotho levels up to the levels observed in control mice and increased cFos expressions in liver. Liraglutide treatment also further increased FGF-21 proteins in liver and plasma.

**Conclusion:** These data suggested that liraglutide might tissue specifically activate FGF-21 activity in adipose tissue through the  $\beta$ -Klotho-FGFR-3 complex and in liver through  $\beta$ -Klotho-FGFR-1-3 complex. And liraglutide not only restored FGF-21 mRNA and protein expression, but also significantly increased FGF-21R,  $\beta$ -Klotho and further increased cFos, which demonstrated that liraglutide maybe have a direct effects on FGF-21 activity. However, after rosiglitazone treatment, the decreased plasma FGF-21 might be just a response to insulin resistance improving. Our study demonstrated that there have been additive effects of HFD, ApoE deficiency, and hypoadiponectinemia on insulin resistance, that FGF-21 resistance was present in this model and that liraglutide decreased the insulin resistance, at least in part, by increasing FGF-21 action.

**Once weekly GLP-1 receptor agonist albiglutide vs prandial lispro added to basal glargine in type 2 diabetes: similar glycaemic control with weight loss and less hypoglycaemia**

V.L. Fonseca<sup>1</sup>, B. Ahren<sup>2</sup>, F. Chow<sup>3</sup>, J. Gross<sup>4</sup>, R. Ratner<sup>5</sup>, S. Johnson<sup>6</sup>, M. Stewart<sup>7</sup>, F. Yang<sup>7</sup>, L. Leiter<sup>8</sup>, J. Rosenstock<sup>9</sup>;

<sup>1</sup>Tulane University, New Orleans, USA, <sup>2</sup>Lund University, Lund, Sweden, <sup>3</sup>Prince of Wales Hospital, Hong Kong, China, <sup>4</sup>Hospital de Clinicas de Porto Alegre, Rio Grande do Sul, Brazil, <sup>5</sup>MedStar Health Research Institute, Hyattsville, USA, <sup>6</sup>GlaxoSmithKline, Research Triangle Park, USA, <sup>7</sup>GlaxoSmithKline, King of Prussia, USA, <sup>8</sup>St. Michael's Hospital, Toronto, Canada, <sup>9</sup>Dallas Diabetes and Endocrine Center at Medical City, Dallas, USA.

**Background and aims:** GLP-1 receptor agonists (RA) and prandial insulin are 2 options for advancing T2D uncontrolled on insulin glargine (GL) + oral agents. Harmony 6 was a randomized, open-label, active-controlled trial with primary endpoint at week (wk) 26 and continued treatment to wk 52 that tested once-weekly (QW) albiglutide (ALBI), a GLP-1 RA, vs thrice-daily prandial insulin lispro (LIS) both combined with titrated GL.

**Materials and methods:** Basal insulin-treated patients (mean A1C 8.45%, weight 92 kg) with A1C 7–10% ± oral agents (no sulfonylurea) entered a run-in standardization GL period followed by randomization to ALBI 30 mg QW (n = 282) or LIS (n = 281) and continued on metformin and/or TZD. GL was titrated to target FPG 4.44–7.22 mmol/L. LIS was adjusted per pre-specified algorithm based on BG monitoring. ALBI could be uptitrated to 50 mg QW based on progressively lower A1C targets (> 8% for ≥ wk 8 and < wk 12; ≥ 7.5% for ≥ wk 12 and ≤ wk 26; and ≥ 7.0% for > wk 26 and ≤ wk 48). Hyperglycemia rescue was permitted in both treatment arms based on progressively lower A1C thresholds.

**Results:** A1C was reduced from baseline by −0.82% and −0.66% with ALBI and LIS, respectively, meeting primary non-inferiority endpoint at wk 26 with further A1C decreases by week 52 among completers. Weight changes were sustained to wk 52: ALBI, −0.96 kg; LIS, +1.66 kg (Table). Mean GL dose increased in both groups. Adverse events of interest through wk 52 with ALBI/LIS were: nausea (13.0%/2.1%); vomiting (7.0%/1.4%), injection site reactions (9.5%/5.3%), and hypoglycemia (32.6%/49.8%).
